Superintendent G. H. Goodhue, of the Five Bears M. Co., says he has bought the North Canyon cyanide plant of F. W. Day, and will move the same to Genesee valley, near Genesee, as soon as the condition of the roads permit. It will be put up at the site of the Centennial mill, owned by the Five Bears. The company will do its crushing in the present 10-stamp mill, but they are making arrangements to add a grinding mill. After the quartz has been passed through the stamp mill it will be delivered into the grinder and then cyanided. The tunnel of the Centennial, which is being driven to develop the Five Bears, is in 510 feet. It is being run on the hanging wall of the vein. Development of the quartz lode, southeast of the Shoofly bridge, is in progress. The tunnel is in 120 feet, and three shifts are driving. Goodhue says they are ready for resumption of cement crushing at Iron Bar as soon as spring opens.

It is reported work has begun on the Peter quartz mine in the north arm of Indian valley, near Genesee.

San Diego County.

Mining operations at the High Peak mine, near Julian, have been resumed under A. B. Hall, manager of the Julian Con. M. Co. The steam hoisting works at the new shaft of the Helvetia have been moved to the 165-foot shaft at the end of the 425-foot tunnel in the High Peak, to replace the gasoline plant damaged by fire. The management will put in heavier steam hoisting machinery.

W. Z. McDonald, of the Cleveland-Pittsburg mines, near Escondido, says he is preparing to put in heavier hoisting machinery and improved methods of handling the ore. Work will be resumed on the vertical shaft, which it is proposed to sink to depth of 500 feet.

Siskiyou County.

J. Johnston of New York City, of the Headwaters G. M. & M. Co., operating mine at head of main fork of Humbug creek, near Yreka, reports having made a strike 250 feet in on the Terror tunnel. It shows a 4-foot ledge of ore that assayed $10 per ton in free gold. Preparations will be made to open this mine on larger scale and ship the ore to the smelter at Keswick as soon as the roads will permit. The properties owned by the Headwaters M. & M. Co. comprise the Lucky Jack, Terror, Mabel, Kittens, Annie, Lucy, Major, 29th of April and 4th of July quartz mines.——The Van Brunt property, having river frontage of 4 miles, has a water right out of south fork of Indian creek, near Fort Jones, and can be worked early and late in the season, says M. L. Gordon, superintendent. Several improvements have been made. D. I. Jackson is manager.

J. C. Woods, operating the Minetta B, or Suspension Bridge claim, near Fort Jones, on a lease, reports making satisfactory cleanups.——The Gordon mine is in full operation. ——J. Wells of Happy Camp is operating the Doolittle property at Clear Creek.——The Portuguese Creek mines, which are owned by Wood & Cuddihy of Happy Camp, has been leased to Scott Valley parties, and they have put the sluices, ditches and pipe line in condition to work.——The Fort Gough group, owing to short time between sale and opening of the mining season, was not able to equip the plant to work their best ground and are working at the old diggings, which are said to be paying well. J. W. Martin is superintendent.

The heavy rain storms of the past ten days caused heavy freshets and floods in all the streams, which will clean them out, although causing much damage, says the Yreka Journal. In the mining streams all the accumulated tailings and debris have been swept away, leaving the miners a clear field for operations, but filled up many claims, besides washing out dams.

Trinity County.

J. Hughes, F. Farris and J. McDonald have bonded the Gambler mine at Hayfork. They intend running a tunnel in below the former workings.

Tuolumne County.

A strike of miners at the Rawhide and App mines, owned by W. A. Nevills, is reported to have practically tied up business at Jamestown. The strike at the App has been on for several months, but last week the miners walked out at the Rawbide. Most of the strikers are Austrians and but few of them understand English. They are armed and have posted pickets to prevent Nevills sending men to the mine to take their places.

Superintendent De Sallier of the American Exploration Co. says he has men at work at the Kanaka mine, near Groveland, and work preparatory to full operations is going ahead. There are 900 feet of track to be laid.——At the Galena mine, on the Phelan ranch, work is progressing in the tunnel.——Moody & Jones have the mill at Big Creek running on ore from the De Ferrari mine at Deer Flat. The mill is equipped with five stamps, and power is obtained by means of an overshot water wheel. The recent rains have provided an abundance of water and a steady run is expected.

While grading for the foundation for the air compressor at the Longfellow mine, near Groveland, a pocket of gold-bearing quartz was taken out from a few inches below the surface, says the Groveland Prospector. The compresser is in place and two drills will be put to work. An 8x12 Dodge rock breaker has been put in and a 6-foot Frue vanner is being set up. The 5-stamp mill is run by a distillate engine. A pumping plant is in operation at the dam on the flat below the mill. Superintendent Partington expects to start full operations by March 1st.

P. J. Port of Oakland has bought the Contention mine near Columbia, also the Bates millsite.

The Dresden G. M. Co., having headquarters at Jamestown, has been incorporated and is working at the New York tunnel at Table mountain. —— M. R. Clement, of San Francisco, has bought a two-thirds interest in the Toledo mine, 2 miles southwest of Tuttletown, also a two-thirds interest in the Big Indian quartz mine.

Yuba County.

Construction work is under way on two gold mining dredgers on the Hallett place, 10 miles east of Marysville, for the Hammon Co. J. D. Cameron is superintendent. The machinery and all the material is on the ground at the site of the dredgers and twenty-five carpenters are at work, making a total of sixty men. The excavation where the two dredgers are being built is 500 feet in length and 200 feet in width, with a depth sufficient to float them when finished. Three pumps are being run by steam power to keep the water from the excavation while the foundation is being laid.

COLORADO.

Chaffee County.

The damage done to the Buena Vista smelter at Buena Vista by the recent fire has been repaired and the plant resumed operations.

Clear Creek County.

Operations are in progress on Ida May group of the Saxon Mountain M. Dev. Co., near Georgetown. A contract has been let to drive a drift south in the lower workings.

The concentrating tables for the Con. Gem M. Co. mill, the Newton Annex, at Idaho Springs, are being set up. From the batteries the ore will run to ten tables, thence to six slimers, and thence to Frue vanners. The proliminary work of lining the ore chute in the Gem raise from the Newbouse tunnel has been completed, and 380 feet of the lining laid.—— A flat reduction of 50 cents per ton is announced from the scale of treatment charges in use in the Gilpin - Clear Creek section by the Chamberlain - Dillingham samplers.——The City Council of Idaho Springs has granted the K. R. S. Milling Co. a permit to build a plant for treating tailings below the Newton mill. The company has closed a deal for treatment of the tailings from the Renshaw mill. Strange Bros. have charge of the work.

Work is progressing on the Gold Belt tunnel, near Silver Plume. It is expected five lodes will be cut by this tunnel within the next 500 feet, cutting them at a depth of from 100 to 300 feet. As soon as the snow leaves the company will put in a plant of machinery. Men will be put to work in the upper workings of the Mary Etta mine.

Custer County.

The O. W. Murphy M. Co. of Florence, which owns several claims and the Rocky Mountain smelter in Custer county, will improve the smelting plant. A Corliss engine will be used in generating electricity for propelling machinery at the mine, furnishing light, water and power for operating a mill the company is to build at the mine, the capacity of which will be 200 tons a day.

Fremont County.

On Howard creek, in western portion of Fremont county, near Howard, the lime depesits, owned by the Colerado Fuel & Iron Co., are the scene of extensive operations, and machinery is being placed. Improvements to the extent of $75,000 are being added and shipments of lime rock will began this week, says the Times. Last summer, an extension of the Denver & Rio Grande was built to the quarries at Howard. Since the first of the year work has been under management of Superintendent Gerard of Denver. Machinery is being set up, buildings erected and preparations made to handle heavy output. The machinery being placed will have daily capacity of 1000 tons; 100 men will be employed. The lime will be shipped to the Pueblo smelters and steel works.

The United Oil Co. is preparing to drill

four more wells, near Florence. It is the plan of this company to keep four strings of tools in operation all the time.——The National Oil Co., which was organized, expects to begin drilling next week. It bas oil land 3 miles south of Florence.

Gilpin Couoty.

The Stacey group of seven claims between Rollinsville and Gamble gulch has been sold to F. Augustus and others of Centreville, Ia. The group has been developed by shafts and tunnel workings. They will start another tunnel, which will give additional depth.

Denver parties are reported arranging to take hold of the Procunieur mine at Wide Awake, near Central City, under lease and bond. It is equipped with a plant of machinery and top buildings and the main shaft is down 200 feet.——Lefevre & Co. are driving ahead the main tunnel of the Mountain Monarch M. Co., in Gamble gulch, near Rollinsville. The company will also drift on the two veins which they have cut. G. E. Churchill is superintendent and the company expects to start operations on the Colorado-Maurer group, on the opposite side of Gamble gulch.

Stewart & Co. of Denver have a lease and bond for two years for $10,000 on the Smuggler group, in Moon gulch, near Central City, and have started developments. The group will be developed by a tunnel wbich has been driven 150 feet.

Sinking has been resumed at the Shamrock mine, near Russell Gulch, whicb is operated by the Electric Spark G. M. Co. The shaft was 350 feet dcep and will be sunk an additional 100 feet. The shaft shows a 12-inch streak of smelting ore. Drifting is also being carried on in the 350-foot east and west levels. A 6x8 friction hoist has been set up. G. Rogers is superintendent.——The Town Topics G. M. Co. has 20 men at work on the leasing system and regular shipments are being kept up, production being altogether of smelting grade ore, says the Central City Register-Call.

On the Star of Gilpin mine, near Russell Gulch, local and Denver lessees are putting in machinery and will start sinking next week.

The Gauntlet G. M. Co. is extending levels at deptb of 350 feet and indications are said to be improving. They are hoisting copper, iron and lead ores and expect to make shipments next month. The ore carries values in gold and silver. Iowa parties are the owners and operators of this group, which is on the east end of Quartz hill, near Central City, and they are preparing to put in a boiler of 60 H. P. capacity. After the installment of the boiler it is expected arrangements will be made to sink the main shaft another 200 feet. The main shaft is down 375 feet and they are on the Matt France vein. L. D. Hobson is manager.

S. Roberts and T. P. Thomas of Russell Gulch, working in the west 400-foot level of the Old Town mine in Russell district, have received returns from a shipment of 198½ tons, which was sent to tbe Jackson mill at Idaho Springs, and which made 89 tons of concentrates. Tbe returns showed a net return of $9544.37. An addition is being made at the Old Town mine, which will be used for new hoist room and for the compressor and electric plant. The new hoist is of 100 H. P. capacity. The compressor will be 16x18 and will run eigbt drills. Sinking operations are still in effect, the sbaft being down 1480 feet, and it is expected the shaft will be down to 1500 feet by Marcb 1st. The shaft shows a vein 10 feet wide. When the new plant is in running shape the daily output is expected to be 200 tons. Tbe present daily product is 50 tons, which is being divided between the Hidden Treasure mill and the Rocky Mountain concentrator on North Clear creek at Black Hawk. Tbe working force, including leasers, is sixty men. The property, which includes the Old Town and Wautauga groups, is owned and operated by G. K. Kimball, Jr., of Idaho Springs, F. E. Himrod of New York City, and Pittsburg men, who formerly owned the Wautauga.

Gunnison County.

(Special Correspondence.)—The strike made by W. H. Hurley & Co. on the Camp Bird claim is being opened up, making at least four promising properties within a radius of 1 mile. The Camp Bird is 1 mile west of the Independent at Bowerman. The vein is a large one carrying free gold in quartz with copper pyrites, malachite, iron sulpbides and oxides. In running a drift and open cut 15 feet in length seven tons of shipping ore has been taken out, besides milling ore which is on the dump. One wall seems to be a soft diorite.

The I X L group is ½ mile south of the Camp Bird and owned by Morris & Ford.——The Copper Queen is near the Camp Bird.——Little depth has been gained by any properties in tbe district. The surface is broken by rolling hills, covered with growth of white pine and aspen with some white spruce and yellow pine. The country is covered quite deeply with talus and soil. Few veins outcrop and good float is not abundant. Much of the surface for 2 miles from the Independent in every direction is claimed and held by location stakes, the "slide" being from a few feet to more than 20 feet in depth.

The country is granitic, with gneiss, diorite, schists, various porphyrites and dykes of basalt cutting tbrough. To the south and east an area of quartzite prevails. Lime also occurs. This area is somewhat mineralized—containing gold, copper and some silver ores. The granitic area is gold bearing, with copper ores in several of the mines.

Bowerman, Feb. 21.

The Copper Sulphide group in Box Canyon district, near Pitkin, has been bonded to A. Hahnewalt et al. of Leadville. They will start development work this week.——The Golden Islet group is being operated under management of G. Brant, president of the Brant M. & M. Co. of Roosevelt, Idaho, under bond and lease.

Hinsdale County.

In the Pride of America claim, which adjoins the Big Casino, at Lake City, Gannon & Kranichfeld have opened up a body of lead, gray copper and zinc ore, which is 6 feet wide. Assays show values of 100 ounces in silver, 36% lead and some gold. They will sink on the ore body.

Lake County.

The low-grade ores handled at the A. Y. and Minnie mills, in California gulch, Leadville, are complex in character, says the Times, consisting of sulphides contaiuing lead, zinc and iron, with silica. As the ore comes from the mine it is dumped into bins holding 200 tons each, whicb form the upper part of the mill. From the bins, the ore goes through Dodge crushers, thence down a chute to automatic feeder, and into the Huntington mills, where it is ground tbrough a 35-mesh screen. The pulp from the Huntingtons passes through hydraulic sizers, thence onto concentrating tables. Tbe slimes are dried and shipped to Germany, where they are said to be used in manufacture of paint. The daily product of clean concentrates is 100 tons, which is sold to the smelters.——The Wallace mine, under lease to M. Starne, is shipping iron ore from the old workings. Development work is being carried on.

Pitkin County.

All the men are back to work in the Smuggler mine at Aspen, says the Aspen Democrat. Manager Hallett and Superintendent Carey have bulkheaded off the section where the fire started, and since doing so the air in the stopes is said to be better than it has been at any time since last summer. No more trouble is anticipated from this source.

Sao Juan County.

Work has been resumed on the Northern Light group on Boulder mountain, near Silverton, says Manager Sisson. He expects to tap the lead by the crosscut tunnel, which is now in 650 feet. Air drills will be put in.

The Esmeralda mine, in Minnie gulch, near Silverton, is sinking the main shaft with two machine drills and is down 195 feet. Tbis property has been a steady shipper during the past tbree years. Seventeen men are at work under Superintendent J. Glanville. Shipments from the mine the past year averaged twenty-three cars per month, of a value of $35 per ton. The mine is equipped with hoisting and compressor plants. W. R. Hollis is manager.——The lease on the Spotted Pup, on King Solomon mountain, near Silverton, is said to be improving, and tbey have eleven cars of ore broken down and sorted, ready for shipment, that will run $100 per ton. There is exposed in the main drift a shoot of sbipping ore 2 feet wide, from which samples were taken, and the lessees expect to have twenty cars of ore ready for shipment when the trail is opened.

The Lackawanna group, on Kendall mountain, at Silverton, which has been worked the past five years by the Four Metals Co., whose main offices are in Pueblo, has 2500 feet of work in drifts, tunnels, raises, etc., completed. Preparations are being made for a 50-ton concentrating mill to be put up on its millsito on the Animas river. The mill will be connected with the upper workings of the mine by a tramway until the lower crosscut tunnel is completed. This group consists of ten patented claims.

San Miguel County

The power used in the mill of the Double Eagle G. M. Co. in Bridal Veil basin, near Telluride, is water, but it is intended to install electricity in the summer. This will make it possible to continue operations without cessation during the dry period of the year when the water supply may be low. Electric drills will be put in this spring and tbe number of men in the mine increased, says Manager Litchfield.

Saguache County.

T. R. Harpel, president of the Steel Canon M., M. & I Co., operating near Villa Grove, says in sinking 30 feet from tbe breast of a 160-foot tunnel a vein of ore 17 feet wide was opened, carrying $16 in gold, silver, lead and copper. The company has 1000 tons of ore on the dump at another mine. A concentrator is being built.

Summit County.

The Gold Dust-Puzzle lease at Breckenridge, operated by Hoyle & Hoyle, has cut the Gold Dust vein in the crosscut. The crosscut was started from the main level of the Puzzle at 2200 feet from the mouth of the tunnel. It is in 300 feet.——Moon, Weaver & Kerse are driving ahead the lower tunnel of the Carbonate, on Mount Baldy, above timber lino. It is in 315 feet and is expected this week to cut the lead ore shoot which was cut in the upper tunnel. Assays show an increase in the gold values contained in the ore over similar ore taken from the upper tunnel.

Teller County.

The A. E. Carlton Leasing Co. has started up the Hull City placer property at Cripple Creek. The main shaft in the Hull City is down to deptb of 1250 feet. The water is in the shaft for 200 feet. It is thought the leasing company will extend the Hull City levels into tbe Findley, which adjoins on the north. The Hull City will put eighty men at work.

The Milwaukee Mutual G. M. Co. has been organized to operate a lease on the Hoosier claim on Tenderfoot hill, Cripple Creek, and has started operations. The company will sink tbe shaft from the 570-foot level 100 feet deeper, and later the shaft may be sunk to the 1000-foot point.

Lessee Wright, operating the Thompson claim of the Elkton mine, at Cripple Creek, is shipping at rate of 100 tons a day.——Tbe Midget mine on Gold hill, Cripple Creek, is making steady output of forty tons daily. All the ore is of smelting grade. The Midget is owned by F. G. Peck and J. F. Burns et al.

The work of unwatering the upper levels of the Hull City mine, at Cripple Creek, began last week by A. E. and L. G. Carlton, and when finished those levels will be cut up into blocks and leased. The shaft has been sunk to depth of 1250 feet, and tbe water stood at the 1050-foot level. Carlton Bros. and J. S. Murphy hold tbe lease on the Hull City, as well as on the Findley mine, adjoining. They have resumed operations on the Findley with fifty men and will double the number tbis week. The Findley was idle for two months, while a compressor and plant of hoisting machinery was being put in. M. Whelan is building a cyanide mill of 100 tons capacity on his lode claim on eastern slope of Ironclad bill, below tbe W. P. H. mine, at Cripple Creek. A new ore shoot has been cut on the Gregory lease of tbe Elkton Con. G. M. Co. by Lessees W. R. Hughes, G. Birtcber, D. Daniels and J. J. Ford. Returns of $152 per ton were received from a local sampler on a shipment of twenty-four and one-half tons.

The Vindicator mine on Bull bill, Cripple Creek, is sending out an average of forty tons of ore per day, ranging in values from one to three ounces per ton. The production will be increased after tbe trouble with water is overcome, as it is now impossible to work some of the lower levels. There are 200 feet of water in the shaft.——The Tunnel M. & L. Co., operating, under lease, the Abe Lincoln mine in Poverty gulch, is sending out a steady production of a car of ore per day, averaging $30 per ton.

Superintendent Judson, who has charge of driving the Hower tunnel into Trachyte mountain, near Cripple Creek, will put in a heavier plant of machinery, including an air compressor. The tunnel bas been driven from tbe east side of the hill for a distance of 1400 feet. It will require 600 feet more driving before the tunnel is under the crest of the mountain, where they expect to cut the ore body tbat outcropped at surface.

The Four Brothers claim, on the east side of Beacon hill, Cripple Creek, near the St. Thomas, has been leased to Baker, Pearce & Maynard. Work has begun.

The Big Twenty M. Co., which is driving a tunnel into Grouse mountain, near Cripple Creek, reports work progressing. The tunnel is expected to cut one of the water courses. Being 1800 feet below the level of the National Hotel in Cripple Creek, it will drain several mines in the district, says the Times. The company has one machine drill at work and more drills will be put on. The tunnel is in 430 feet from the portal on the south slope of the mountain.

IDAHO.

Ada County.

The Gold Ring and Joe Dandy mining claims, in Deer Creek mining district, have been bonded to W. McKinley of Boise for $45,000. The Comstock, Lucky Bill and Independence mining claims, in same district, have also been bonded to W. McKinley for $30,000. These properties are said to be extensions of the Big Ledge vein. Work will be begun tbis week.

Blaine Couoty.

The Queen of the Hills group of mines, adjoining the Minnie Moore mine, in Wood River district, near Hailey, has been sold to N. Trewoek of Salt Lake City, Utah, and Chicago, Ill., men for $250,000.

Boise County.

Manager Thorne has men at work putting up the mill at tbe English company's group of claims in Gambrinus district, near Idaho City.

The concentrator of the United M. Co. at Horseshoe Bend will be enlarged tbis spring. Two freighters are hauling concentrates from Horseshoe Bend to Emmett, and one car a week is shipped to the smelter at Mackay.

G. Leighton, superintendent of the Idaho G. M. D. Co., operating near Pearl, says he is putting in a steam plant to serve the company pending installation of electrical equipment. In the development of the group ho says he has driven on $20 ore for 350 feet, with an 8-foot breast exposed. A concentrator capable of treating 100 tons daily will be built this year.

Idaho County.

The Rescue mine, in Warren, is now owned by the Ontario M. & M. Co., composed of Ontario and New York men. The mine has been re-named the Pandora, and six otber claims added. A 5-stamp mill is said to be on the mine, with engines, boilers, hoist, etc., and 1000 feet of tunnel.

Lemhi County.

Tbe management of the Gold Dust mines, at Leesburg, proposes doubling the capacity of its mill.

Nez Perces County.

D. Laverty, manago• of the Pittsburg-Idaho M. Co., which owns a group of ten claims in Lolo district, near Kamiab, says tbe company's lower tunnel is in 560 feet, giving a vertical depth of 300 feet. The tunnel will be run in 40 feot farther, when crosscuts will be driven. Tbe workings in tbe lower tunnel are now beneath tbe shoot of gold-copper struck in the upper workings.

Shoshone County.

During the year 1903 the Cœur d'Alene lead-silver mines produced ore of gross value of $10,929,977, exceeding the output of 1902 by $2,600,000. The producing mines were:

Federal M. & S. Co. (four mines)	$4,993,423
Bunker Hill & Sullivan	1,788,344
Morning	1,671,510
Hercules	953,585
Hecia	733,585
Frisco	482,930
Hunter	158,625
Silver King	108,375
California Consolidated	39,600
	$10,929,977

The total tons of lead produced was 104,177 of gross value $7,500,744. The silver content was over 6,000,000 ounces, having market value of approximately $3,400,000, silver averaging a fraction above 53½ cents for the year.

Tho Alabama M. Co. has been incorporated to operate in Beaver mining district by W. Fablo, J. H. Scott, O. E. Trojanowski, R. Campbell, C. and J. Murphy and L. J. Columbus, all of Wallace.

Washington County.

The Mineral City smelter at Mineral City bas blown in. Improvements have been made in tbe motbod of handling ore and waste, and work is under way on a second furnace. In changing the way of handling slag the managoment has done away with six men on each shift. The alteration consists in carrying away the slag by means of water, which is made to pass beneath the furnace in sufficient volume, and with a current strong enough, to keep the slag moving to the waste pile.

MICHIGAN.

Houghton County.

At the Wolverine mine, near Calumet, the mill is stamping 1075 tons of rock daily and thirty power drills are in commission. The lower workings are reported in a good grade of ground. The Wolverino is adding to its ground reserves.

Tbe miners at the Champion mine of the Copper Range C. Co. at Painesdale went out on strike last week because of a cut in wages. They were offered reduced house rent and cheaper fuel by Manager Hubbard, but the men refused to go to work, and, going to the Trimountain and Baltic mines of tho same company, called the men out there, thus tying up the entire Copper Range Con. system and 2500 men are out.

Keweenaw County.

At the Allouez mino at Allouez No. 1 shaft has reached a depth of 430 feet and

sinking is progressing at the rate of 75 feet a month. The shaft is expected to cut the Kearsarge lode in October.

MISSOURI.

Jasper County.

The Waring Chemical Co. is reported building a plant at Joplin for carrying into practical operation experiments which have been made in the extraction or separation of zinc from water pumped from mineral-bearing ground. The company also expects to purify, by the use of chemicals, the zinc ore after it is washed and considered ready for market. The water will be pumped into a receptacle 20 feet above the surface, says Manager G. W. Waring, where the chemicals will be mixed with it, after which the compound will be allowed to flow into a sieve-like receptacle and fall in drops to a receiver at the surface. The separation of zinc particles is supposed to take place during the descent and will settle in the bottom of the receiver, and the water will run off through other receivers, where any remaining particles might settle. The quality of zinc thus produced will be the pure product.

MONTANA.

During month of January $212,161.78 worth of gold and silver passed through the United States Assay Office at Helena. Of that amount $180,710.56 was produced in Montana, against $130,899.63 for the same month last year. Of the total value there was but $1144.71 in silver, the balance being in gold. The report of Assayer B. H. Tatem shows this increase in the total production of the State is due largely to the increase of the gold output from Fergus county. The receipts for January from the counties of Montana were:

	1903.	1904.
Fergus	$52,670 35	$98,499 05
Granite	2,936 32	7,657 43
Lewis and Clarke	22,348 70	25,233 63
Madison	17,423 35	30,577 91
Park	21,498 49	12,147 05
Beaverhead, Jefferson, Broadwater, Deer Lodge, Powell and Silver Bow	14,022 42	5,595 49

The receipts hy States were:

	1903.	1904.
Montana	$130,899 63	$180,710 56
Idaho	6,754 64	3,821 69
British Columbia	18,904 72	22,936 43

Deer Lodge County.

The arsenic plant of the Washoe smelter at Anaconda is expected to be in operation by March 1st. It will operate in connection with the flue and smoke stack system built last year. Owing to a break in the hoist at the Diamond mine in Butte last week, the number of men at the Washoe smelters is temporarily reduced. In the mill the force has been reduced from seven to four crews. Repairs on the Diamond hoist are being made.

Jefferson County.

At Basin, the Basin R. Co. proposes to increase its concentrator of 1500 tons daily capacity to 2500 tons daily. Power is furnished by a 1000 H. P. boiler plant feeding an 800 H. P. cross-compound Corliss engine. Crushing and concentrating equipment consists of four 10x20 crushers, eight sets 16x30 Cornish rolls, ninety jigs, sixty-nine tables, eight Frue vauuers and one slimes table. Water for concentration is supplied by a flume 12,400 feet in length with capacity of 4000 inches, which is supplemented by one duplex power pump of capacity of 300 gallons per minute, one triple power pump of capacity of 800 gallons per minute, and a pump of 300 gallons per minute. An electric lighting plant is maintained at the mill consisting of three dynamos. The mill is on Boulder river, and in view of the large amount of tailings to be disposed of daily plans are being made for a series of dams extending a distance of 8 miles through the canyon below the mill, and the company is securing the land necessary for the construction of these dams.

The Grey Eagle mine, near Basin, is shipping a carload of ore to the smelter daily. The ore is a sulphide, carrying copper, gold and silver, says Superintendent Frecburg. He will increase the output to two cars per day.

J. B. McCabe of Helena has the Robert Emmett mine, near Wickes, under a $20,000 bond. The vein is 10 feet wide. McCahe has also bonded for $25,000 the Nonparoil claim on Granite creek, in Madison county, and placed men at development work.

Madison County.

The Alder M. Co., which owns the Kearsargo mine near Virginia City, has increased its holdings by huying the Rough Rider lode claim for $10,000, the Cora Locke claim for $1200 and the Roosevelt claim for $500. The Alder Co. started up the Kearsarge 60-stamp mill last week.

H. U. Foster, in charge of operations at Washington Bar, 20 miles from Pony, for the Blackhawk M. Co., says during the past two months work has heen in progress on the Bi-Metallic mine, which is hoing developed hy a tunnel now in 500 feet. In running the last 40 feet a shoot of ore was cut 3 feet in width of average value of $20. There are soventy-five tons of ore on the dump, takon out while driving the tunnel. More men are boing put on. It is intended to build a 15-stamp mill in tho spring. The values in tho ore are mostly gold, with some lead.

Park County.

G. R. Tuttle of Butte, president of the Precious Metals M. Co., which owns holdings in the New World mining district at Cooke City, states that two smelters will be built at that plaec in the coming summer. A sawmill is heing huilt at Cooke which will turn out material for the company's buildings. A large numher of men will be put to work in the spring. The smelters will treat custom ores as well as ores from their own mines.

NEVADA.

Esmeralda County.

(Special Correspondence.) — In Gold Mountain mining district tho Kelly's group is heing opened up with satisfactory results. Thoy are down nearly 300 feet on the St. Louis mine and are drifting in ore. L. E. Chiatovich, owner of tho Rattlesnake group of mines, is expected to return from an Eastern trip next month and will start operations on his mill and mines. V. M. Katuricb & Co., leasing on Corbett No. 1 mine, hy the first of April will have 150 tons of good grade free-milling ore ready to mill. This claim is one of the Rattlcsnake group and is 2 miles west of the St. Louis mine. At Tokop no one is working at present.

Camp Kelly (via Lida), Feb. 20.

The Anaconda-Tonopah M. Co. has heen organized at Salt Lake City, Utah, to develop a group of claims in Lone Mountain district, near Tonopah. The officers are H. P. Myton, D. S. Murray, J. W. Langley and E. D. Thompson.

The Goldfield-Vindicator M. Co. has been organized by W. H. King, E. H. Airis, L. H. Farnsworth, W. H. Tihbals, Jr., R. L. Colburn et al. of Salt Lake City, Utah, to operate at Goldfield, south of Tonopah. A. W. Tihbals of Salt Lake City, Utah, is superintendent.

Lincoln County.

Operations at the Bamberger De Lamar mines, at De Lamar, are progressing. The mill is now crushing ore at average of 300 tons daily. Amalgamation plates are heing put in and the quantity of ore treated will be increased.

The Bethel G. M. Co. has been incorporated at Salt Lake City, Utah, to operate a group of claims 70 miles west of Calientes, in an unorganized mining district. The officers are W. D. Colhath, R. E. Ross, W. D. Mathis and H. L. Berkey, the last named being manager.

Nye County.

O. B. Dawson, of Caldwell, N. J., has bought a group of claims south of and adjoining the Halifax, near Tonopah, and expects to begin development on them this week.

The Silver Star-Tonopah M. & M. Co. of Nevada has been organized in Washington, D. C., hy C. D. and F. E. Van Duzer and G. B. Ackerman. The mines are near Tonopah.

Storey County.

O. Belau, who has a lease on the Chollar croppings, near Virginia City, has bought the mill at the Alta mine, and is overhauling it preparatory to putting in electric power. It is reported the Justice, New York and Alta companies will put the shaft of the latter company in repair and prospect their mines from that point.

Drill hole No. 7 in the Occidental ground, near Virginia City, is down 715 feet, with the bottom in quartz and porphyry, the quartz showing some value hy assay.

Superintendent J. R. Ryan of the Ophir mine at Virginia City reports for week ending February 20: 1800 level, the northeast drift following ore vein was advanced 12 feet; total length 362 feet. The ore was too low in value to save for milling. In the stope over this drift they worked on the 2d, 3d, 4th and 5th floors and extracted ore of good quality. A break in the electric power line cut off the power for running hlowers and work was stopped for twenty-four hours.——1900 level, the east crosscut started 200 feet from tho south boundary line of mine was extended 13 feet in porphyry; total length, 30 feet.——On the 2000 level, advanced the northcast drift 14 feet; total length, 718 feet. Ore of good grade was extracted from this drift during its progress. The ore in the vein in the face of drift is second grade. ——Total extraction of ore for the week from the 1800 and 2000-foot levels, 221 mine cars assaying on basis of gold value $78.84 per ton. Shipped to Selby S. & L. Co., four railroad cars of ore in bulk.

NEW MEXICO.

Colfax County.

The Oro Dredge Co. at Elizahethtown is getting its dredger into shape to start operations next month, says the New Mexican. Machinery for the company has hoen shipped into the district, via Springer.

Grant County.

On tho White Pine group of four claims at Fierro, owned by W. D. Murray and J. W. Welch, there are four shafts from 40 to 45 feet deep, all in ore. Ore takon from shaft No. 1 is reported to have given assays of one-half ounce gold, eleven ounces silver and 5% copper: shaft No. 2 shows similar ore.

Otero County.

E. A. Hersporger is shipping ore from the Garnet mino at Jarilla. —— F. B. Schermerhorn, manager of the Three Bears group at Jarilla, is putting in hoisting machinory. The hoist is 20 H. P. Air drills and other equipment are also going in.

Rio Arriba County

A wagon road is heing built to the claims of La Grande Placer M. Co., says J. P. Rinker of Tros Piedras, superintendent. The company will put a dredger on the Rio Grande river.

The Franklin Placer Co. has men at work on its mines at Red Rivor under Manager J. A. Knowland.

The Keystone M. Co. and the Bromide M. Co., near Tres Piedras, have consolidated under name of the Keystone-Bromide M. Co., for running a tunnel from baso of mountain on Bromide claim to cut shaft of the Pay Roll mine. The distance to be covered is 6300 feet and tbe tunnel will crosscut tbe following claims: Hutchinson (formerly the Bromide), Silver Ground, Helen, Silver State, Camp Bird, Blucher, Big Four, 44-49, Central, Hawkeye, Arroya, Oversight and Pay Roll. At the Pay Roll shaft the tunnel will cut 680 feet helow tbe surface. The tunnel is to drain the properties and for development purposes. It will have double tracks. For some distance from its mouth it will follow the Bromide vein, passing under the present shaft workings. Then it will turn off and crosscut tho formation the rest of the distance. The Bromide shaft is down 150 feet and opening up shipping ore. This shaft will he connected with the tunnel by an incline of 65 feet. The mineral is said to he brittle silver and copper. The Pay Roll has been the principal working of the Keystone Co. The shaft is down 250 feet and is in a hody of ore carrying copper and gold. The tunnel will he known as the Dillon development tunnel. J. C. Dillon of Bloomsburg, Pa., is president of tbe Keystone M. Co. Men are putting up buildings and have started work on the tunnel. Machine drills will he used.

San Miguel County.

Las Vegas reports say the new mill of the Bonanza C. Co. started operations last week on ore that has accumulated on the dumps.

Sierra County.

The Prosper G. M. & M. Co. intends to resume operations on its mine near Hillsboro.——Eigbt dry washer claims are being worked in Pittsburg district in Apache canyon. The average yield is said to be eight ounces each day for the entire outfit. No quartz mines have yet been discovered nor any water developed.

The Empire G. M. & M. Co. is developing properties near Hillsboro. J. Churchill of Dodge City, Kans., is part owner. ——H. R. Taylor, manager of the South Percha G. M. & M. Co., says they propose to make improvements on the South Percha mines.

A. G. Brower of Utica, N. Y., president of the Hillshoro G. M. & M. Co., says they will resume operations near Hillsboro as soon as a water supply can be obtained. Surveys have been made for water rights. It is the intention of the company to build a water tank on the highest divide hetween the pumping station on the Percha and the mill on Ready Pay gulch.

Kingston reports say the Lady Franklin mine on Kentuck mountain, near Kingston, which has been in operation for the past two years under Manager Cuns, has closed down.

Socorro County.

E. Craig of Silver City, president of the Ernestine M. Co., operating the Last Chance mine near Mogollon, says his company will resume operations on the Last Chance mine and mill. The leaching plant will be increased from a capacity of 1200 tons a month to 2000 tons, and the output of the mine from 50 to 100 tons a day. Sixty men will be employed.

OREGON.

Baker County.

The Dixie Meadows mine, in Quartzburg district, near Sumpter, is steadily producing hullion. The mill is not of sufficient capacity to handle the quantity of ore being mined, and more machinery will be added to raise capacity to 100 tons daily.——The California mine, in Cahle Cove district, is again working. Repairs to the damaged shaft by an explosion have been made and the tramway is in full operation again transporting ore from mine to mill. Snow so far has not impeded the work.

Milling operations have started on the Cyclone mine, near Baker City. Manager Waddell laid off the men sinking in the shaft and says he will keep in the mine for the present hut fifteen men. Connections have been made for electrical power.

W. Cable has a bond on the Sheridan group at head of Wind creek, near the Porcupine group, near Sumpter. There are five claims in the Sheridan. Development work will start as soon as the snow leaves.

Tho Morning mine, near Greenhorn, has been sold to G. W. Beggs et al. of Tacoma, Wash., who also bought the Andorson group on Beaver creek. The ledge of the Morning group is covered hy ten claims. A crosscut tunnel has been driven 500 feet and will cut parallel ledges at a depth of 400 feet. The mino is equipped with a 5-foot roller mill and a 35 H. P. engine.

W. E. King, manager Portland Commercial M. Co., operating in Mormon Basin, near Baker City, says his company has eight properties in Mormon Basin, near the Morning Star group. Operations are being concentrated on the Rainhow group. A Chilean mill, having daily capacity of twonty tons, will be put up there in the spring.

Baker City reports say two large snow-slides on Rock creek last week passed over the Chloride, Geiser-Hendryx and Maxwell mines, destroying the shaft houses, mills and upper workings in their path. No one was killed. The full extent of the damage is not known. In the United Elkhorn district, 16 miles from Baker City, northwest, two slides occurred, says Foreman H. H. McGregor of the Chloride mine. The first slide startod high up on the mountain and came down directly over the Chloride mine, carrying away the motor and power houses, compressors and blacksmith shop and all tbe other buildings at the mine except the boarding house, which is some little distance away from the mine. He says it is supposed the Maxwell mine, a neighboring property, is also damaged, and the Geiser-Hendryx mine was buried under 30 feet of snow. All the telephone lines in that entire section were broken down.

E. F. Zinns of Houghton, Mich., president of the Merchants Placer M. Co., operating in Burnt River district, says he is putting in additional machinery, including a pump weighing 7500 pounds, with capacity of throwing 1200 gallons of water per minute. The boiler weighs 7½ tons. The placer grounds to be oporated by this company are on Pine creek. A ditch 7 miles long from Burnt river will carry the water which will be conserved in reservoirs for use during the season.

Jackson County.

At tbe Shorty-Hope mines, west of Ashland, the Golden Spike drift is in 440 feet. Since Feb. 1 it has been driven under contract. It will continue to the Shorty-Hope shaft, which will be sunk to connect. It is proposed to enlarge this shaft.

Men have been put to work on the Mountain Lion mine, near Applegate. The ledge averages 2 feet in width and is opened on seven lovels. It assays $15 per ton. This year the north end of the vein will be opened. The mine is equipped with a reduction plant using cyanide and amalgamation. The mine is owned by the Mountain Lion M. Co.——Burner & Gilkins have leased Caris creek, on Missouri flat, in lower Applegate section, and will begin placer mining operations next month.

Josephine County.

Tho Oak Flat hydraulic placer mine, on Illinois river, has been bought by Grant's Pass men, including F. Fetsch, T. B. Cornell and J. Moss. The Oak Flat placers are on lower Illinois river, 20 miles from Selma station, on the Grant's Pass-Crescent City stage road. They comprise several hundred acres of deep channel diggings and are equipped with hydraulic mining plant. Water is derived from Briggs creek, a tributary to the Illinois.

Development work on the Ingram-Ramsey copper mine, in Slate Creek district, will be resumed. It is under bond to S. Bowden. A shaft will be sunk on the ledge to depth of 150 feet. The mine is 17 miles southeast of Grant's Pass and near the Kerby road.

The Bone of Contention mine, Williams district, south of Grant's Pass, has been sold to Johnson, Catterline & Co. of Portland. The Bone of Contention is equipped with an 8-stamp mill and other machinery for development and operation. The new management proposes to complete a

crosscut tunnel to tap the main ore body at a depth of 350 feet.

Wallowa County.

The Great Northern C. & G. M. Co. has been organized to develop a mining group on west fork of the Wallowa river, 25 miles south of Lostino. It comprises ten full claims and two water rights. The claims have been worked three years and are said to show two ledges of copper ore. It carries some silver. W. H. Stalker of Baker City is manager. As soon as the snow disappears operations will begin, and the company expects to begin shipping ore the coming summer. The principal owners are A. Wurzeller, G. Mack, T. & G. Schuler and J. Dunn of Josepb and E. W. Rumble and A. E. Cray of Lostine.

Wheeler County.

T. J. Smith of Fossil says coal deposits are being opened up in Wheeler county. He says the coal is bituminous and of coking quality. The fields are 12 miles south of Fossil, on Rowe Creek mountain. The vein shows a thickness of 7 feet. The local fuel demand is being supplied and shipments to outside points will begin next montb.

SOUTH DAKOTA.

Custer County.

H. F. Ratte, in charge of operations of the Ivanhoe G. M. Co., 9 miles east from Custer, says he has equipped the mine for deep work. He has put in a steam hoist, boiler, air compressor, pump and drills. There are several openings on the ground of the Ivanhoe Co. in all of which ore is showing. The plant is being set up over the principal vein and the company expects to sink to depth of 500 feet. This vein carries values in free gold aud sulphides.

Lawrence County.

Manager H. Bischoff of the Lexington Hill G. M. Co., operating near Deadwood, says they will build a 40-stamp mill and convert the present 20-stamp mill into a concentrating plant, for treatment of the pyritic ore from the El Dorado, whose product will be shipped to a smelter. Pending completion of the new mill the 20-stamp mill will continue amalgamation, concentrating and cyaniding. The new mill will be a few rods from the present buildings and will embody amalgamation, concentration and cyaniding. In the meantime a tunnel is being driven from a point on the hillside a short distance above the mill, under the horizontal siliceous ore bodies, to facilitate delivery of ore direct to the mill. This tunnel is in 335 feet and has 50 feet to go. Raises will then be made to the ore bodies.

The Big Four G. M. Co. has material on the ground on Deadwood gulch, near Deadwood, for rebuilding its hoisting plant that was burned last month.

The Hidden Treasure G. M. Co. is preparing to put in machiuery at its property on Deadwood gulch, says Superintendent W. Lawler. The mine is 2 miles from Lead, near the Pennsylvania, Big Four and Hidden Fortune mines.

The Queen of the Hills G. M. Co. is putting in a steam hoist and other machinery on its group at head of Whistler gulch, near Pluma. Siuking will be resumed, and the shaft will go to 500 feet before drifting and stoping is started. J. W. McClure of Des Moines, Iowa, is president.

Work continues by the Ohio-Beaver Creek M., M. & Dev. Co. on Beaver creek, west of Spearfish, where it owns an area of 1000 acres. Manager D. Clark says the ore body is 25 feet wide, carrying $5 per ton gold. W. Watson is superintendent and T. C. Lentz of Columbus, Ohio, is president.

L. T. Wolle of Cambria, Wyo., secretary of the American M. Co., says the company will resume work on its Ragged Top and Spoarfish property. It is reported this company proposes building a power plant at Spearfish Falls and transmission by electricity of power to various parts of the Black Hills. The company will sink a shaft at or near the Dacy shaft.

Pennington County.

A strike is reported made by the Clara Belle M. Co., near Hill City, at depth of 225 feet. In a drift on this level following course of vein the ore has widened out to several feet, says F. Hebert, prosident and principal owner. There is a 2-stamp mill on the ground, and Hobert expects to begin milling ore again in the spring.

The Black Hills C. Co. is continuing operations on its property west of Rochford at Copper Reef mountain, after an idleness of a few months, during which time the mine was permitted to fill with water. The water has been removed and crosscutting is again under way ou the 800-foot level. J. B. Taylor is superintendent.

The Gopher M. Co. is working two shifts at the Lena mine, near Hill City. The destruction of this company's hoisting plant by fire has not interrupted its work.

UTAH.

Box Elder County.

The Great Northern C. M. Co. has been organized at Ogden to develop properties in the Sierra Madre mining district. The officers of the company are: A. W. Agee, president; D. Conway, vice-president; S. H. Browne, secretary and treasurer.

Iron County.

A heavier pump is being set up at the Johnny mines, at Stateline, and will be followed by opening up the ore bodies on the 300-foot level, says Director Clift.

Juab County.

The Mammoth M. Co. of Tintic district, near Eureka, during the past year marketed 13,573 tons of ore, for which it received $145,452.91, with its earnings from all sources aggregating $156,040.02, according to its annual report. During the same period disbursements reached a total of $130,460.31, of which $64,918.80 was for labor, $21,679.41 for supplies, with accidents incurring an expense of $12,-279.07. The report of underground operations by Superintendent S. McIntyre Jr. shows an opening of 5 feet of $50 copper ore on the 500-foot level, which has been followed for 18 feet on its strike. Associated with it are 8 feet of high-grade copper-bearing quartz. On the 700-foot level 5 feet of ore valued at $20 per ton, in addition to the second-class ore, are shown. On the 1000-foot level, 240 feet north of the shaft, in the Spar stope, the report shows ore, while 10 feet north of the stope is a streak of quartz which yields gold. This is being followed and 100 sacks that average $380 gold per ton have been collected. In the winze which has been sunk 200 feet below the 1900-foot level high-grade ore has occurred along with the second-class. S. McIntyre of Salt Lake City is president and manager.

The Raymond M. Co. and the Illinois M. Co. are preparing to consolidate their holdings near Eureka, Tintic district. The main workings of the Raymond having been put down to depth of 1500 feet from a collar near Gemini ground, further exploration of the zone will be made, says Manager J. C. Sullivan of the Raymond.

Piute County.

P. A. H. Franklin of Salt Lake City, manager of the Log Cabin and other mining properties in Marysvale section, says Superintendent Larsen will let a 300-foot contract on the L. & N. mine, near Marysvale. Franklin & Co. have a bond on the L. & N. group of claims. He intends to run a 2000-foot tunnel the coming summer.

P. A. H. Franklin, president of the Gold Dev. Co., operating in Gold mountain section, near Marysvale, says in the Log Cabin tunnel the strike is being developed. A crosscut showed a width of 80 feet, with $5 per ton in gold. The Franklin tunnel has advanced into the hill 700 feet, and is expected to go to 1000 feet. The tunnel on the Elephant group has attained a length of 500 feet and will continue to the 1000-foot station under the present contract.

Salt Lake County.

Ores are again passing over the Old Jordan division of the United States tramway at Bingham to the smelter in the valley.

The Copper Princc Con. M. Co. has been incorporated by T. Jacobson, C. K. McCornick, C. H. Post, H. A. McCornick and M. Badger. The property consists of the Copper Prince and Silver King groups of eighteen claims in all, adjoining the Continental-Alta mines at Alta on the south. It is intended to clean out the old workings and increase development.

To complete its equipment in Salt Lake valley, the United States S. Co., at Bingham, will follow up its installation of lead blast furnaces with a refinery, says the Tribune.

The King Standard Oil Co. has been organized at Salt Lake. The company owns forty-eight placer mining claims. The officers are W. H. King, J. T. Hammond, J. Watson and E. A. Smith. They will start operations in the oil field this week.

On No. 2 level of the Red Wing Extension mine, near Bingham, milling ore is opened up, showing values in lead, copper, gold and silver. A thousand feet of work has been done, in tunnel, drifts, lifts and winzes. Water is increasing in the incline. The company proposes to build a mill.

The Butler-Liberal mine, at Bingham, is being equipped with machine drills, says Manager Jacobs. The lower tunnel is expected to reach its objective point in July.

The Utah C. Co.'s mill in Bingbam canyon, near Bingham, began reduction of ores this week, says Managing Director Jackling.

Summit Conuty.

Additional water with which to supply the Kearns-Keith mill at Park city is being developed by Manager Dailey and the tonnage at the plant will be increased.

The management of the Daly West M. Co., Park City, produced and marketed ores and concentrates of value of $2,382,-257.52, and paid dividends aggregating $1,332,000 during the past year. The annual report shows there was marketed from Daly Wost ground proper 44,476 tons of ore, for which $2,373,103.30 was received, the metallic contents averaging 58.5 ounces silver, 20.5% lead, 2.1% copper and 76 cents gold, with 15.6% zinc. From Quincy ground, during same period, there was forwarded to tbe smelter 17,870 tons of ore, that brought $416,-737.37, the average contents being 49.6 ounces of silver, 17.25% lead, 1.6% copper, and 86 cents gold, with 7.7% zinc. Of concentrates from the mill there were sent out 16,580 tons, valued at $592,416.87, with contents of 53.8 ounces silver, 31.4% lead, 2% copper, and 80 cents gold, with 17.7% zinc. The shipping ore from Daly West proper netted $30.88 per ton and that from Quincy ground $23.32, while the concentrates afforded profit of $35.73. During same period the Daly West expended for labor and on items connected directly with operations underground $461,579.76; for transportation of its output, sampling, etc., of same, $105,721.62. In exploratory work and opening up of new sources of ore $100,135.10 was paid, while in operation and maintenance of the concentrator $79,002.37 was paid, with the general expense amounting to $51,301.37; for improvements in the mine $14,903.44, and at the mill $17,406.78, while during same period $17,456.75 was applied to adjustment of claims arising from the explosion of July, 1902, with miscellaneous disbursements amounting to $9144.05. The report of Superintendent J. A. Kirby shows that during the year, in extraction of ores and prospecting of territory, 13,203 feet were driven, while the shaft is now sinking from the 1400-foot level to depth of 1700 feet.——F. W. Sherman, superintendent of the mill, after reporting its operations, advises that with the additional power being installed the mill will be able to reduce 10,-000 tons of ore per month, and with completion of the tailings plant under construction the earnings from those sources will have been increased $250,000 per annum.——The metals produced from the ores mined with comparisons with the production of 1902 are summed up as follows:

COPPER.

	Pounds.
1903	3,160,824
1902	2,403,670

LEAD.

	Pounds.
1903	34,742,791
1902	29,806,000

GOLD.

	Ounces.
1903	3,195.28
1902	2,943.96

SILVER.

	Ounces.
1903	4,382,222
1902	3,575,796

ZINC.

	Pounds.
1903	22,573,355
1902	19,477,443

Tooele County.

The new concentrator of the Honerine Co. at Stockton has commenced operation, says Superintendent Raddatz. The plant includes a "slimer," and will handle 450 tons of ore daily. The mill and its equipment has cost about $85,000.

Utah County.

The Oriental M. & M. Co., of Scofield, has been incorporated by J. S. McNeal, T. Kelter, H. C. Lee and N. M. Madsen. The company owns thirteen claims in Nebo Basin mining district.

WASHINGTON.

Ferry County.

Tho lessees of the Nob Hill mine, near Republic, will open the property at greater depth. A tunnel will be driven from a point down the hill, from which the railroad can be reached by an easy grade, and an additional vertical depth of 120 feet attained, which will give 160 feet more depth on the dip of the vein. A 2-drill compressor has been set up. A boiler will be removed from the Little Cove mine and used to furnish power. Drills will be operated on the north drift on the upper tunnel level.

The Nantucket M. Co. will resume work on the Louverne and Sentry claims, 2 miles south of Laurier. The claims cover a contact vein, traceable by iron croppings 12 feet wido, says the Spokesman-Review. A shaft was sunk 60 feet, from the bottom of which a crosscut was driven 50 feet. An incline shaft was sunk on tho vein 81 feet and a drift 12 feet along the vein, from which assays showed $5 per ton in gold, silver and copper. The vein at the bottom of tho shaft is 16 feet wide.

The Orient mine, on Toulon mountain, 2½ miles southeast of Orient, is again in operation. It is equipped with a 3-drill air compressor, and a steam boiler, which have been used to drivo a tunnel 800 feet. The tunnel is said to havo cut four blind veins. A winze was sunk 30 feet deep and showed ore which ran $15 a ton in gold. It is proposod to drive the tunnol ahead to cut the main vein.

Snohomish County.

It is stated that the Everett smelter will be blown in about March 1st. Manager E. B. Braden says he has arranged to take all the ore that the Continental mine, near Porthill, Idaho, will send. The Continental has already shipped fourteen or fifteen cars to the East Helena, Mont., plant. Tho Monte Cristo mine, near Everett, is snowed under and nothing is being done. There is a large amount of Monte Cristo oro at the smelter and it is boing treated in the arsenic plant. Tho arsenic is being shipped by the carload from Pittsburg, Pa., for use in making plate glass. It sells for 3½ cents a pound laid down in the East, and tho freight is 70 cents per 100 pounds. The product is said to be chemically pure arsenic. Mr. Braden is in charge of the East Helena plant of the American Smelting & Refining Co. and will manage that, as well as the Everett works.

Stevens County.

The Little Giant mino, in Pierce lake district, near Northport, has been prospected with a diamoud drill, which showed ore in a 6-foot quartz vein, which runs $30 a ton in copper, gold and silvor. In addition to several open cuts and small shafts on the vein, it has been opened by a shaft which was sunk 80 feot. The mine is equippod with a steam hoist.

WYOMING.

Carbon County.

A strike has been made in the Congo properties, near Dillon, showing bornite and galena, with values also in gold and silver. The Congo group consists of eight claims, ½ mile below head of Jack creek. The vein is 25 feet wide in the shaft. The group is 40 miles from the Union Pacific railroad and the ore teams will have a downhill haul all the way. Arrangements are beiug made to begin shipments of high-grade ore. It is reported R. Ferris has secured control of the Honchen & Flamme discoveries on Jack creek. They have also organized a company for development of the Congo group. On the Honchen & Flamme work will be started this week.

The North American C. Co. of Encampment is increasing operations. Several hundred men have been employed to develop the Ferris-Haggerty mine, to reconstruct the Southern Wyoming tramway and to remodel its reduction works. The works are expected to produce 200 tons of matte copper per day.

Fremont County.

The International Mining Association has been organized in Paris, France, to co-operate with the Belgo-American Oil Drilling Co. in building a railroad to the Lander oil fields and in the development of the Lander, Popo Agie, Salt Creek, Salt Wells and other oil fields in the State in which the Belgo Co. has holdings. Work on the railroad will be started as soon as contracts can be let. It is thought that the railroad will be run from Casper to Lander via the coal, iron, gold and soda districts in the Platte river and Sweetwater river sections. M. Landeur of Paris is a director and Governor Chatterton and J. Knight at Cheyenne are the American directors of the company.

FOREIGN.

AUSTRALIA.

Queensland

During December, 1903, in the Mount Morgan mine development work was carried forward at the 750 level. A drive running west at this level from the Crown shaft, several hundred feet, passed through a large body of copper ore of payable grade; and from the face of this drive cousiderable prospecting has been done by diamond drills. A bore has been put in westerly 527 feet, and another northwesterly 300 feet. A little copper ore was met, but its value and extent are not yet ascertained. The ore bodies in this property do not appear to have any defined continuity or strike, but occur in irregular masses in a haphazard manner, and it is never safe to assume that a body of payable ore discovered in one level will extend to the next level, either above or below, although in some instances these bodies prove of considerablo thickness. The mass of copper ore in the western drive was met 130 feet from the Crown shaft, and it has been proved of sufficient magnitude to yield 60,000 tons of payable stone for every 10 feet of depth it is mined. In the stopes above the 750-foot level some large faces of siliceous ores are being opened, one face, 35 feet wido,

yielding payable stone, which is treated for gold, in the course of which treatment the copper contents are leached out and subsequently precipitated. Gold ores are still being obtained from the 650 level, and from several faces in the 574 and Linda levels, and from the upper or oxidized zone of the mine. The steam shovel, which was for some time operating on the overburden above the 196 level, has finished its work at that part of the mine, and the engineer in charge is preparing to lower this machine to the 225 level, where it will work for a considerable time. The returns for the month of December, 1902, from the Mount Morgan mine showed 20,420 tons of stone treated for a yield of 11,878 ounces of gold, while these for the period under review give 19,834 tons for 9323.75 ounces, a falling off in value of stone treated of 8s 9d per ton. The copper precipitated by the company for the months of November and December aggregate 22 tons. These precipitates are valued at 75% of metallic copper.

In the Chartors Towers field, says the mine commissioner for that district, an instance of the work that can be done in shaft sinking occurred during the month of December, 1903, in the Queen Central Block mine. The shaft has four compartments, 3½ feet by 4 feet each. The country sunk through was grey granite. Twenty miners were employed in three shifts; and in four weeks they sank 140 feet and timbered 31 feet. This is a record for this field, if not for Australia.

Western Australia.

At Boodalyerrie, in Pilbarra section, the owner of a small windmill battery has recently crushed sixteen tons of quartz yielding sixty ounces of gold per ton, says the W. A. Journal. For the purpose of testing lodes the windmill battery is applicable, as well as for making returns from claims, and under certain conditions this form of battery can be advantageously employed. The question of fuel being a serious item, and heavy freights for cartage prohibiting removal of ore to the nearest available battory, the windmill battery may be used. It is reported that the battery referred to has already treated 100 tons for a total yield of 800 ounces of gold.

AFRICA.

Cape Colony.

The De Beers Con. M., Ltd., operating the De Beers, Kimberley, Premier, Bultfontein and Dutoitspan diamond mines, at and near Kimberley, has issued its report for year ending June 30, 1903. Following are details of receipts and expenses:

Diamonds recovered	£5,241,173
Mining expenses	£ 907,145
Floor (treatment) expenses	524,723
Charge of lands	20,813
General and office expenses	133,513
Total expenses	£1,586,194
Net mine earnings	£3,654,979
Interest, rents, etc	134,031
Balance from previous year	798,686
Total credits	£4,587,696
War expenditures, balance	£ 30,542
Interest paid	316,075
Life Governors' interest purchase	100,000
Debentures redeemed	167,900
Depreciation accounts	751,415
Added to insurance fund	100,000
Reserved for investment	200,000
Total charges	£1,665,932
Balance	£2,921,764
Dividends paid	2,175,000

The statement of operations shows:

	De Beers and Kimberley.	Premier.	Bultfontein.
Loads, blue hoisted	2,370,503	1,987,543	318,410
Loads, blue washed	2,561,940	1,989,598	317,185
Loads on floor	2,135,283	1,571,859	482,159
Diamonds recovered, carats	1,574,190	594,890	76,573
Carats per load	0.61	0.30	0.24
Value	£3,819,651	£1,021,277	£118,102

To this must be added diamonds, aggregating 227,477 carats, valued at £281,434, recovered from 1,347,115 loads of tailings and debris washed; and 2672 carats, valued at £706, recovered from old concentrates. This makes total recovery of 2,475,802 carats, valued at £5,241,173 (or $25,419,689).——In the De Beers mine development work included 24,858 feet tunnels and 722 feet passes; Kimberley mine, 12,894 feet tunnels and 1165 feet passes; Premior mine, 2130 feet tunnels and 91 feet passes; Bultfontein mine, 4703 feet tunnels and 147 feet passes. The Dutoitspan mine is being developed and provided with machinery. The main shaft was sunk 65 feet, to depth of 785 feet, while 1493 feet tunnels were driven. The acting manager's report says: At the De Beers mine mud-rushes have continued to be of frequent occurrence, but although there were twenty-nine rushes, only on two occasions have they been attended with fatal results—two natives being killed in each. The total length of tunnels filled was 15,344 feet, as compared with 6989 feet for the previous year. The cost of clearing away the mud and retimbering the tunnels amounts to 20s per foot. However, the greatest loss thus caused was in shutting down of the filled places, and by the blue ground being mixed with the mud. Frequent occurrence of mud during the year reduced output of the De Beers mine. A new drain tunnel is being driven around the mine in the hard rock below the black shales. It is exected this will take up some of the water, which now finds its way into the mine and causes the mud. Judging from the appearance of the open mine, it should not be long before the hard rock is exposed; and it is hoped that when this does appear they will be able to collect all the water, and thus end the mud-rusbes, as in the case of the Kimberley mine. The central electric power station has capacity for delivering 3000 H. P., which will soon be utilized to extent of 1300 H. P., and by end of next fiscal year 2500 H. P. will be required.——The directors' report shows that since the close of the fiscal year, the De Beers explosive works, at Somerset West, have been completed and are producing dynamite, supplying present requirements at Kimberley. Contracts have also been made with the principal mining groups in the Transvaal, whereby they will buy from De Beers works, half their monthly requirements for period of seven years from September 1 last. The company's account against the Imperial Government was settled. A claim of £54,641 was made, and the government paid £30,000.

BRITISH COLUMBIA.

Boundary District.

The Canadian Pacific Railway has made a reduction in freight rates on ore in the Boundary. It has reduced the price of haulage of ores from Phœnix to the smelters at Grand Fork and Greenwood from 37½ cents per ton to 30 cents. H. E. Macdonell, general freigbt agent of the Kootenay lines, states the company is hauling an average of between 14,000 and 15,000 tons weekly. It is expected the Boundary ore tonnage, which last year was 686,614 tons, will reach 1,000,000 tons for 1904.

East Kootenay District.

J. P. Larsen & Co. are developing a deep placer mine on Wild Horse creek, near Fort Steele, by means of a drift running several hundred feet into the gravel banks on the west side of the creek.

Under the provisions of the lead bounty act there is $75,000 coming to the owners of Kootenay shipping mines from the Dominion government, says G. O. Buchanan of Kaslo, disbursement agent for the federal government.

During month of January 76,000 tons of coal were mined at the three collieries of the Crow's Nest Pass Coal Co. This is the largest monthly output in the history of the company, says the Rossland Miner. Coal Creek gained 4000 tons over December. The largest day's output at each colliery was: Coal Creek 1513, Michel 1489 and Morrissey 889. The operations at Michel were hampered by the explosion in No. 3 mine. The coke production for the month was 23,000 tons.

Rossland District.

The White Bear mine, at Rossland, is again making ore shipments.

Vancouver Island.

At Texada island, the Copper Queen shaft is down vertically 600 feet into the vein. The Marble Bay mine is down 460 feet and the ore body is showing up satisfactorily. The Cornell is down 500 feet and is shipping copper ore to the smelters regularly. There are two freighters carrying ore to the smelters and three passenger steamers weekly from Vancouver to the docks at Texada.

H. E. Young, of Atlin, and associates have taken over the mines of the Mounts Sicker & Brenton M., Ltd., near Mount Sicker. They will increase development work and make shipments of ore. The property comprises seven crown-granted claims, crossing the Chemainus river and extending east and west on both Mounts Sicker and Brenton sides. The claims are in the schist. There is a compressor plant and hoisting machinery at the mine. J. H. Brownlee, of Atlin, is manager.

West Kootenay District.

A quarter interest in the Spyglass group at Poplar Creek has been sold to J. A. Magee of Seattle, Wash.

Yale District.

At Kamloops the result of the last year's work on the Iron Mask mine, on Coal hill, is reported satisfactory. Preparations are being made to put up a smelter and other equipment. The other metalliferous mine of importance on which operations were carried in 1903 was the Copper King, which started shipments of ore to the smelters in November. On Tranquille creek, a tributary of Thompson river, a drodger was steadily operated during entire season, working with two 12-hour shifts. The channel was dredged to depth of 18 feet, the best values being found, however, in a streak of clay at 15 feet.

E. H. Thomas of Whatcom, Wash., secretary of the company, says they are putting up a 40-stamp mill on the Mount Baker Yale M. Co.'s claim on Siwash creek, 4 miles above Yale, on Fraser river.

MEXICO.

Chihuahua.

(Special Correspondence).—The Moctezuma M. Co. of Santa Barbara is enlarging its works at the mines.

The American S. & R. Co. of Chihuahua proposes to establish in this State a smelter to cost not less than $1,500,000.

Chihuahua, Feb. 20.

The Los Angeles, Cal., men who bought the Navaganties and Santa Maria properties have merged them into the Parral & Santa Maria M. Co. They have prepared to sink the shaft another 100 feet on the Navaganties and to run a tunnel to strike the ledge on the Santa Maria. This tunnel will strike the ledge 300 feet from the surface. W. Faust is president and A. Reverall vice-president and manager.

The output of Santa Eulalia camp is estimated at 20,000 tons per month, says the Chihuahua Enterprise, and this promises to be greatly increased in the near future. The advent of two California companies has infused new life into the camp. Diamond drills are at work on numerous properties, and the amount of ore to be shipped from now on is a question of transportation facilities, the car capacity of the mineral road being taxed to its utmost.

Queretaro.

(Special Correspondence).—The mines of O. Y. Braniff & Co. in the Maconi district, northeast of Queretaro, has been taken over by the United M. & Dev. Co. of 666 Broadway, New York City, N. Y. E. G. Spillsbury, part owner in the company, has also closed a deal which includes several mines adjoining the Braniff & Co. mines. The United M. & Dev. Co. has a total of forty-six mines, all of which are in operation, four smelting and refining works and a tract of timbered land 20 miles square, which assures a supply of charcoal. In addition to the 400-ton electrically driven plant now in operation another 300-ton plant will be built in the summer. Concentrating plants will be built and plans are being drawn for the first of these, which will have a capacity of 150 tons of ore per day. The company's mines and smelters will be connected by a railroad system aggregating 38 kilometers. E. A. Tays of Queretaro has been appointed manager.

Queretaro, Feb. 20.

Sonora.

(Special Correspondence).—N. Thomas et al. of Chicago, Ill., have bought the Cerro Pocito mining properties in Magdalena district. They will put up machinery, including a 5-stamp mill.

Hermosillo, Feb. 20.

Cananea reports say M. P. Wright et al. have bought the Los Amigos group of mines (formerly the Realito), in Ures district, near Minas Prietas. There are twenty pertenencias in the claim and a gold-bearing ledge 14 feet wide. The mines are antiguas and along the ledge are a number of open cuts from which ore was taken. This was treated by arrastras. The old workings will be cleaned out and shafts sunk below them. It is also intended to build a quartz mill. In addition to this property, Wright has also denounced forty-eight more pertenencias of mining ground adjoining the Los Amigos.

NEW ZEALAND.

The gold dredgers operating at Otago and Southland during year 1903 recovered a total of 87,130 ounces of gold, with an average of sixty and a minimum of seventy-seven dredgers in operation each week of the year. Same district in 1902 yielded 106,369 ounces. In West Coast district an average of twenty dredgers produced 30,619 ounces in 1903, against 30,416 ounces in 1902. During almost the whole of the winter months the river fluctuated so much that steady dredging was difficult in the Molyneux river, says the Otago Times, and for a period of several weeks in July and August, after the heavy fall of snow, the cold was so intense that operations were almost completely at a standstill. The gerge dredgers had a hard year, and were only able to work intermittently, with the result that a considerable portion of the actual working time was occupied in treating the traveling drift. This, combined with the heavy cost of coaling, has made working very expensive. A number of companies worked out their ground and closed up during 1903; but, on the other hand, a few new ones were floated, the most attention in this connection being devoted to the Waikaia and Upper Clutha districts.

The bullion production of the gold fields of Auckland district of northern New Zealand for year 1903 amounted to £959,665 4s 5d, against £803,094 15s 3d for 1902, distributed as follows:

	£	s.	d.
Ohinemuri	859,739	8	1
Thames	54,589	12	8
Coromandel	35,336	3	8
Total	959,665	4	5

Personal.

T. CLARK of Placerville, Cal., is in San Francisco, Cal., on mining business.

F. W. WILLIAMS of Seattle, Wash., is in San Francisco, Cal., on mining business.

C. WEBB of French Gulch, Cal., is in San Francisco, Cal., on mining business.

W. C. RALSTON has returned from Washington, D. C., to San Francisco, Cal.

N. TREWEEK of Salt Lake City, Utah, returned there last week from an extended trip East.

F. X. PELLIER is superintendent of the Minola mine at Park City, Utah, vice G. C. Carlton, resigned.

H. K. MASTERS has resigned as smelter superintendent of the United States M. Co. at Bingham, Utah.

J. A. YERINGTON of Carsen, Nev., interested in Nevada mines, is in San Francisco, Cal., on business.

V. P. STRANGE of Salt Lake City, Utah, is in Nevada examining mines at Tonopah and Goldfield.

P. J. DONOHUE of Salt Lake City, Utah, returned there last week from examining mines in Mexico.

P. N. NISSEN is manager of the Gold Tunnel M. Co., operating near Nevada City, Cal., vice G. Lezinsky.

H. BISCHOFF of Deadwood, South Dakota, is manager of the Lexington Hill G. M. Co, vice E. F. Woodward.

T. DERBY, superintendent of the New Almaden quicksilver mines at New Almaden, Cal., is in San Francisco, Cal.

F. B. COOK of Salt Lake City, Utah, of the Columbia group of mines at Bingham, Utah, is examining mines in Nevada.

E. W. GARRETSON returned to Denver, Colo., last week, after two years operating in the Loon creek section of Idaho.

WM. WEIGELE of the Weigele Pipe Works Co., Denver, Colo., is in Chicago on business connected with the company.

C. F. RAHT, who has been in Mexico in charge of a mine for a Seattle, Wash., company, returned to Sumpter, Or., last week.

E. A. TAYS of Querotaro, Mexico, is manager of the United M. & Dev. Co., operating mines at Maconi, State of Queretaro, Mexico.

H. R. TAYLOR, manager of the South Percha G. M. & M. Co., near Hillshoro, New Mexico, is in Cincinnati, O., on company business.

C. C. DERBY of Mt. Bullion, Cal., manager of the mines of the Mariposa C. & M. Co. in Mariposa county, Cal., is in San Francisco, Cal.

F. H. LATHROP of Salt Lake City, Utah, is in Chicago, Ill., on company business for the Belcher group of mines of Tonopah, Nev.

A. W. TIBBALS of Salt Lake City, Utah, is superintendent of the Goldfield-Vindicator M. Co. at Goldfield, south of Tonopah, Nev.

J. J. CASE, for the past five years superintendent of the Lake Superior Smelting Co. plant at Dollar Bay and Hancock, Mich., has resigned.

R. BOWEN of Cleveland, Ohio, is with the Mine & Smelter Supply Co., Denver, Colo., as special representative of Laidlaw-Dunn-Gordon Co.

J. H. BROWNLEE of Atlin, B. C., is manager of the Mounts Sicker & Brenton M. Co., Ltd., operating at Mount Sicker, Vancouver Island, B. C.

P. B. STEIFER, president and superintendent of the Steifer M. Co. at Nimshew, Butte county, Cal., has returned from a business trip to San Francisco, Cal.

G. R. TELLER of Buffalo, N. Y., secretary of the Con. Esmeralda mine in Nevada, and T. H. Fearey of Quincy, Ill., a director in same company, are in San Francisco, Cal.

W. F. DETERT, president of the Argonaut M. Co. and superintendent of the

Zeila mine, has returned to Jackson, Cal., from San Francisco, Cal.

C. E. GRUNSKY of San Francisco, Cal., is considered the final choice of President Roosevelt for the position of engineer of the Panama Canal Commission.

F. L. SIZER, who has been at Sandon, B. C., is now at Nelson, B. C., as a witness in the case of the Star M. & M. Co. vs. the Byron M. White M. Co., an extra lateral right controversy.

Obituary.

I. DERRICK, a pioneer miner of Montana and California, died at Divide, Mont., at the age of 75 years.

GEORGE GARNICK, superintendent of the May Day mine in Tintic district, Utah, died on the 20th inst, at Salt Lake City, Utah.

J. SHERIDAN, a pioneer miner of Sierra county, Cal., and formerly part owner in the Keystone gravel mine at Monte Cristo and the Keystone quartz mine near Sierra City, died at Downieville, Cal., on the 8th inst. Deceased was born in London, Eng., March, 1821.

H. D. SPAULDING, superintendent of the Big Chunk mine near Atlanta, Elmore county, Idaho, was killed on the 14th inst. by a snowslide, which swept away the cabin in which he was sleeping. The slide carried the cabin 250 feet down the side of the mountain. Deceased was a native of Milton, Mass., and a graduate of Harvard University. Prior to going to Idaho, Spaulding operated mining properties near Baker City, Or.

E. MCCLELLAN, a pioneer miner of Clear Creek county, Colo., died at Georgetown, Colo., on the 10th inst., aged 84 years. Deceased was horn in Alleghany county, Pa. Besides the Blackbawk mill at Blackhawk, the Lexington, Faivre & Kipp and Buell mills in Gilpin county, and the South Clear Creek, Mahany and Federal Union mills in Clear Creek county were built under superintendence of deceased. He was formerly interested in the Colorado Central mine.

THEODORE BRUBACK, a railroad and mining man of Salt Lake City, Utah, was accidentally killed on the 18th inst. He went to Park City to inspect the workings of the Daly-Judge and was accompanied through the tunnel by Superintendent McSorley. While ascending a ladder Bruback lost his hold and fell a distance of 20 feet, striking on his head. Deceased was president of the San Pete Valley Railroad and was interested in copper, coal, gold and silver mining properties. He also owned large stone quarries. He was 45 years old.

Commercial Paragraphs.

JESSE J. MACDONALD is now located at 1025 So. Flower street, Los Angeles, Cal.

CHAS. L. TURNER, of C. C. Moore & Co., San Francisco, Cal., has returned to San Francisco from a southern trip.

THE Mine & Smelter Supply Co., Denver, Colo., report a good trade in Cincinnati air compressors, having recently sold two 8-drill compressors for shipment to South Dakota and two 30-drill compressors to Old Mexico.

THE Vulcan Iron Works Co., Toledo, O., will pay full time to any employe who is a member of the Ohio National Guard, when out on parade with their company, at rifle practice, at camp duty, or when serving under the Governor or Sheriff to put down a riot.

THE Allis-Chalmers Co. announce their entrance into the electrical field and that they will take up immediately the manufacture of heavy electrical generators for the largest class of work. Supplementary to their well-known reciprocating engines, they propose, after two years of research, to supply a steam turbine in efficiency equal to the best known in Europe. They have also taken up the manufacture of the Nurnberg gas engine, and have secured from the firm of Escher, Wyss & Co. exclusive rights for the manufacture of their hydraulic turbine. They are now creating their electrical department, at the head of which will be J. F. Kelly, well known in connection with the Stanley interests. He will be the electrical director; associated with him in an advisory and consulting capacity will be W. Stanley, Jr.

THE American Concentrator Co. of Joplin, Mo., report the following shipments recently made: New Century differential motion jigs, Palacios & Trevino Arreola, Monterey, Mex., F. E. Crawford, West Ossipee, N. H.; complete equipments for entire concentrating plants, Washington Zinc Co., Arlington, Wash., Bear Top M. Co., Murray, Idaho: New Century Blake crusher, 12x20 inches, Rossland Power Co., Rossland, B. C.; New Century belt-driven rolls, Maryland High Grade Flint Co., Finksburg, Md.; two-compartment anthracite coal washing jig, Scranton Coal Co., Scranton, Pa.; Knowles' New Century magnetic separator, Payne Con. M. Co., Sandon, B. C.; New Century disintegrating screen, Catherine Lead Co., Fredericktown, Mo.; New Century differential motion jigs and New Century ore feeder to the Denver Ore Testing & Sampling Co., Denver, Colo.

Latest Market Reports.

SAN FRANCISCO, February 26, 1904.

METALS.

SILVER.—Per oz., Troy: London, 26 1/16d (standard ounce, 925 fine); New York, bar silver, 58 1/2c, refined (1000 fine); San Francisco, 58 1/4c; Mexican dollars, 47@48c San Francisco, 45 3/4c New York.

COPPER. — New York: Standard, $12.50; Lake, 1 to 3 casks, $12.50; Electrolytic, 1 to 3 casks, $12.37 1/2; Casting, 1 to 3 casks, $12.37 1/2; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £57 7s 6d spot per ton.

Following are the figures of German consumption of foreign copper for the months January-December, 1903, compared with the same period of 1901-1902:

	1903.	1902.	1901.
	Tons.	Tons.	Tons.
Imports	88,792	80,417	63,155
Exports	9,999	8,903	10,277
Consumption	78,793	71,514	52,878

LEAD. — New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4 3/4c 1000 to 4000 lbs.; pipe 6 1/2, sheet 7, bar 5 3/4c; pig, $4.85. London: £11 5s ℔ long ton.

SPELTER.—New York, $5.10; St. Louis, $5.00; London, £21 15s ℔ ton; San Francisco, ton lots, 6 3/4c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.10@28.40; San Francisco, ton lots, 30 1/2c; 500 lbs., 31c; 200 lbs., 31 1/2c; less, 32 1/2c; bar tin, ℔ lb., 35@37 1/2c. London, £124 17s 6d spot.

PLATINUM. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75@82c ℔ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ℔ flask of 76 1/2 lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 1/2c; extra, 17 1/2c; genuine, 31 1/2c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00; shingles, $2.50 for No. 1 and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ hhl.

CEMENT.—Imported, $2.15@2.40 ℔ hhl.; California carload lots, $2.00 f. o. h. at works; small lots, $2.25 ℔ hhl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $13.60@13.85; gray forge, $12.60; San Francisco, bar, 3c ℔ lb., 3 1/2c in small quantities.

STEEL. — Bessemer hillets, Pittsburg, $23.00@23.00; open hearth billets, $23.00@23.00; San Francisco, bar, 7c to 12c ℔ lb.

No. 1 cast, net ton	11 00@12 00
Iron rails	15 50@16 50
Car wheels	13 50@14 50
Cast borings	4 00@ 5 00
Turnings	8 00@ 9 00

GENERAL SUPPLIES.

ANTIMONY. — New York, Cookson's, 7c; Hallett's, 6 1/2c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8 1/2c; 100-lb. lots, 10 1/2c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15 1/2c; less than one ton, 17 1/2c. No. 1*, 60%, carload lots, 13 1/2c; less than one ton, 15 1/2c. No. 1** 50%, carload lots, 11 1/2c; less than one ton, 13 1/2c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9 1/2c; less than one ton, 11 1/2c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE. —Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11 1/2c ℔ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23 1/2c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3 1/2c per lb.; caustic soda, in drums, 3@3 1/2c ℔ lb.; Cal. s. soda, bbls., $1.20@1.40 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bhls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2 1/2@2 3/4c; powdered sulphur, 2@3c; flour sulphur, French, 3 1/2@3 1/2c; alum, $2.00@2.25; California refined, 1 3/4@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5 1/4@5 3/4c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1 3/4@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

BONE ASH.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.00; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymho, $7.50; Pennsylvania, hd., $14.00; Scoteh, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, bbl., 49c; cs., 54c; raw, hhl., 47c; cs., 52c; Lucol oil hoiled, bhl., 44c; cs., 49c; raw, bhl., 42c; cs., 47c. Kerosene—Pearl, per gal., 21 1/2c; Astral, 21 1/2c; Star, 21 1/2c; Extra Star, 25 1/2c; Eocene, 24 1/2c; Elaine, 27 1/2c; Water White, in bulk, 15c; Mineral Seal, iron hbls., 19c; wooden bbls., 21 1/2c; cs., 25c; Mineral Sperm, cs., 26 1/2c.; Deodorized Stove Gasoline, hulk, 17c; do., cs., 23 1/2c; 86° Gasoline, hulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19 1/2c; Lard Oil, E W. S., hbl., 85c; cs., 90c; Neats-foot Oil, pure, hhl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6 1/2c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 1/2c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, 1/2c. per lb. above keg price. Dry Lead—In hhls., 1 ton and over, 6 1/2c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb., 6 1/2c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

BISMUTH.—Suhuitrate, ℔ lb., $2.00.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—$2.00 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., $1.00.

PHOSPHORUS.—American, ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittshurg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. h. San Francisco, unless otherwise noted.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING FEBRUARY 16, 1904.

752,193—OIL BURNER—E. B. Badlam, S. F.
752,507.—RAILWAY TIE—A. W. Bascom, Spokane, Wash.
752,195.—OIL BURNER—W. N. Best, Los Angeles, Cal.
752,146—CLEANING FILTER BEDS—H. W. Blaisdel, Los Angeles, Cal.
752,026.—DRILL SHARPENER—J. L. Bryson, S. F.
752,027.—SEPARATOR—H. J. Burroughs, Los Angeles, Cal.
752,614.—CLOSURE—E. E. Chapman, Los Angeles, Cal.
752,524.—TURNBUCKLE—E. H. Cowart, Pleasanton, Cal.
752,525.—STORE FIXTURE—E. S. Coy, Wilhur, Wash.
752,146.—BLOTTING PAD—I. Csik, Stockton, Cal.
752,440.—SAWMILL—E. T. Davies, Portland, Or.
752,616.—INDENTIFICATION DEVICE—F. H. De Pue, S. F.
752,529.—ATOMIZER—A. S. Dixon, Los Angeles, Cal.
752,334.—MAIL BAG CATCHER—O. P. W. Ehrhardt, Seattle, Wash.
752,538.—WATER WHEEL—O. H. Ensign, Los Angeles, Cal.
752,541.—CABINET—W. J. Funk, Enterprise, Or.
752,151.—CLOTHES DRIER—C. W. Gies, Seattle, Wash.
752,159.—BOX—E. D. Hamilton, Vancouver, Wash.
752,621.—WIRE STRETCHER—Huerth & Olson, Oregon City, Or.
752,170.—JOINT PROTECTOR—F. W. Krogh, S. F.
752,349.—BATTERY STEM GUIDE—Martin & McComhie, Nevada City, Cal.
752,241.—VALVE—J. W. Master, Los Angeles, Cal.
752,245.—DISK HARROW—P. H. McVicar, Livermore, Cal.
752,095.—MOWING MACHINE—G. W. Newton, Camhria, Cal.
752,355.—WEATHER STRIP—G. L. Parker, Bremerton, Wash.
752,686.—POMADE CAN—E. L. Pitts, Jerome, A. T.
752,587.—CUFF HOLDER—E. L. Pitts, Jerome, A. T.
752,263.—NUT LOCK—W. R. Rose, Auherry, Cal.
752 593.—OIL BURNER—A. C. Rush, Los Angeles, Cal.
752,474.—PIPE—E. Semple, Seattle, Wash.
752,364.—SAW HANDLE—D. W. Solomon, Arlington, Wash.
752,307.—VOTING MACHINE—St. Louis & Jackson, Colusa, Cal.
752,119.—BREAD MAKING MACHINE—S. R. Stearns, Redlands, Cal.
752,481.—SPARK ARRESTER—M. H. Thode, Riparia, Wash.
752,367.—GRAIN LIFTER—H. E. Titamore, Agenda, Cal.
752,270.—FEED WATER HEATER—J. P. Urhanek, Seattle, Wash.

Notices of Recent Patents.

Among the patents recently ohtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

HYDROCARBON BURNER.—No. 752,193. Feh. 16, 1904. E. B. Badlam, San Francisco, Cal. This apparatus is especially designed for the combustion of liquid hydrocarhons of any description—such as gasoline, naphtha, coal oil, etc.—so as to vaporize and hurn them without the formation of carhon deposit in retort or coils. In order to effect this result the liquid hydrocarbon should not he vaporized in long uniformly-heated coils or in spacious heated retorts, the inlets or outlets of which are virtually of the same degree of heat. By this apparatus the temperature of the fluid is gradually raised during its progress from the point of admission to a point where it is finally subjected to the highest degree of heat just before being delivered to the hurner injector in the form of a dry highly-heated gas.

GRAIN LIFTERS.—No. 752,367. Feh. 16, 1904. H. E. Titamore, Agenda, Cal. This invention consists in a novel construction of lifters which are fixed to the finger har at intervals hetween the ends, these lifters heing comhined with the sickle guards at points where the two coincide in such a manner that the guards serve as braces to prevent side motion of the lifters, and the lifters themselves are so constructed as to have two separate points of attachment, whereby they are braced against vertical movement.

BATTERY STEM GUIDE.—No. 752,349. Feh. 16, 1904. W. H. Martin of Nevada City, and A. McComhie of Grass Valley, Cal. This invention relates to an improved guide for stamp stems of crushing mills. Its ohject is to provide a simple adjustahle guide wherein will he done away with the usual holts and like securing means, and a key arrangement provided for locking and for take up.

Books Received.

"Facts Ahout Peat, Peat Fuel and Peat Coke." How to make it, how to use it; what it costs, what it is wortb; its use and value. Illustrated. T. H. Leavitt. Postpaid, $1.10. Publisbed by Lee & Shepard, 202 Devonshire street, Boston, Mass.

"Alternating Currents, Their Generation, Distribution and Utilization," is the title of a new hook on this interesting and important suhject, hy George T. Hanchett, M. E. In view of the fact that there are many who bave a comprehensive knowledge of direct current work, but have only limited information concerning, or experience with alternating currents, this little work is timely. The book is devoted to a simple explanation of the phenomena as well as the apparatus of alternating currents of electricity in their practical phases. 180 pages fully illustrated with half tones and drawings. Price, cloth, $1 net. John Wiley & Sons, New York. Chapman & Hall (Limited), London.

MINING AND SCIENTIFIC PRESS.

Whole No. 2276.—VOLUME LXXXVIII. Number 10. SAN FRANCISCO, CAL., SATURDAY, MARCH 5, 1904. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Grade of Plates in Stamp Mills.

A question of some importance in stamp mill construction is the grade of the mill plates. In most mills the plates are laid on solidly constructed tables, and no means is provided for changeable adjustment. They remain as they were built, at a uniform grade. Over these plates the soft oxidized, more or less clayey pulp from the surface portion of the vein passes. Later, the semi-oxidized ores of the intermediate zone, and still later, the hard, undecomposed ores, containing more or less sulphurets, flow over the same plates at the same angle. It is possible with an ore easy of treatment that this practice may give continuously satisfactory results, but in most cases it will be found that it is good mill practice to change the grade to suit the character of the ore passing over them. A few mills have devices for adjusting the plates at any desired angle, at any time. The accompanying engraving shows the interior of a mill, the Big Indian, near Helena, Mont., where provision has been made to set the plates at any grade which the character of the ore may require. In considering this matter, the quantity of ore crushed per stamp, and the amount of water used or required, are of importance. The usual grade given mill plates is about 1¾ inches per running foot. Within the past few years a novelty has been introduced in some mills, giving plates an increasingly lesser grade as they leave the mortar lip. That is, a plate having a grade of 1¾ inches just below the lip has but 1½-inch grade in the middle section of the plate, and still less at the lower end. This causes the pulp to be retarded somewhat in its flow at the lower end, instead of being slightly accelerated, as is the case where plates have a uniform grade. Practically the same result is accomplished by arranging the plates in a series of steps, giving each section a drop of ½ inch, and all set at uniform grade. The drop causes the pulp to start anew from each step, and no appreciable acceleration of flow occurs. It has also been demonstrated that a drop is an advantage, if not over an inch in height, and amalgam collects under the several drops. This suggests that if the plates be made in narrow strips, and that there be ten, twelve or more drops of ½ inch in length of 12 feet, instead of two or three drops, as is the usual practice, better amalgamation would result.

The grade of mill plates must always be sufficient to permit a free flow of the pulp, and to secure this a sufficient quantity of water must be provided. Heavily sulphureted ores require more grade and more water than those which contain little or no sulphurets. Ores which contain considerable of any mineral of high specific gravity other than sulphurets, such as heavy spar, also require heavy grade of plates and considerable water. In many mills the plates are divided by a strip of wood placed longitudinally along the center of the plate, making two narrow instead of one wide section. The advantage claimed for this is in the fact that, when dressing of plates is necessary, all the pulp from a battery can be turned onto one of the sections while the other is washed with clean water and dressed. Those who do not believe in this practice claim that the overloading of the half section scours off more value from the amalgam already accumulated than is saved by not hanging up the stamps. The preponderance of opinion is against the practice of divided plates, for, if any loss occurs while overloading the plates, it is more difficult to save below on the concentrators, and, while the battery is hung up, no ore is being crushed and no loss is sustained, as the mill simply is somewhat reduced in capacity, though this might be considered a loss by some, where very large capital is invested, and where it is figured that any stoppage of the mill is a loss.

There are those who contend that the amalgamation plates of a mill should in no way be attached to either the mortar or the mortar blocks, for the reason that the constant vibration of the mortar, due to the falling stamps, is imparted to the plate, and, as a result, amalgam is disturbed, loosened and washed down by the force of the flow of pulp. This is in decided contrast to the ideas of those who place an amalgamated copper plate on a percussion table, for the purpose of catching the gold, which, they claim, would otherwise escape. This latter practice has been fruitful of satisfactory results in a number of mills, and it is unlikely that gold is lost on the outside plates of a mill merely from the jar imparted by the stamps. Any such loss would probably only occur where the amalgam on the plates was abnormally hard and when any disturbing element would cause it to crack and crumble, with the loss which is likely to follow.

THE arrastra and patio in Mexico are rapidly being displaced by the stamp mill and smelter. For several centuries the simple, but effective, arrastra and patio have been employed in developing the mineral resources of Mexico, but the demand is now for a more rapid and economical means of reduction of ores. Mexico abounds in mineral deposits, but not all of them are easy of treatment, and, in some instances, the highest chemical and metallurgical skill will be required. At present, however, the ores are being mostly milled, amalgamated and cyanided, or sent to the smelters, but there is an abundance of ore which will not pay the excessive cost of transportation and treatment, which, later, will become available by reason of railroad construction and cheaper and more satisfactory methods of reduction, in which electricity may be expected to take an important part.

WHEN deciding upon a site for a smelter there are many important questions to be decided. Among these are, first, an abundant supply of ore sufficient to justify the expense of building the reduction works. Next a supply of proper fluxing material—silica, lime and iron. These are all important, for no matter what the grade of ore, if it is not available in sufficient quantity, the investment will prove a loss, and unless the ore be self-fluxing—a rare occnrrence—it is useless iu the smelter without fluxes. Another importaut factor is cheap transportation, which will enable ores to be shipped to the smelter at a minimum expense. Fuel must be of good quality and as inexpensive as possible. When there is reasonable assurance that these esseutials can be had, theu, and not till theu, may a smelting project be viewed as an assured success if there is pleuty of money on hand, and expert management be provided.

Mineral or Agricultural Land?

Recently the Government has thrown open to entry and settlement several large tracts of land in California which had formerly been included in the forest reserves. In northern California three of these tracts include portions of the Mount Shasta, Lassen peak and Feather river forest reserves. This is done on the information of forestry experts who have decided that these particular tracts, aggregating 558,000 acres, are better suited to agricultural than forestry purposes. In Mariposa county, in the vicinity of Bear valley, 40,000 acres are also withdrawn from the Yosemite forest reserve and opened to settlement. This latter area is in the heart of the mineral section of Mariposa county, and while certain portions are undoubtedly valuable as agricultural land, unless extreme care is taken by the intending settler he is likely to have his filing contested by mineral claimants. The time to determine the character of land is before filing is made by the agricultural applicant. The law excepts all land "known" to be mineral from agricultural entry, when such "land is more valuable for mineral than for agricultnral purposes." This is, in the very nature of things, while not ambiguous, an uncertain quantity, for the mineral vein or deposit which is unprofitable to-day may be the paying mine of the near future. In the area included in the Mariposa lands which have been thrown open to settlement, arc numerous gold-bearing veins and pocket mines, the value of many of which can only be determined by time. Of course, many of these are known, but it is improbable that all of the veins or deposits have becn located or discovered, and the experience of the past has shown that in snch a region the mineral industry is of greater value to the country than the product of agricultural pursuits. Indeed, in that particular region the farms increase or decrease in value with the rise and fall of success in mining, for the eutire conuty is dependent upon the mines for support—farmers aud townspeople alike—for mining is the only support of the region, which is too far removed from other markets to make agriculturc profitable. It is to be hoped that when applications are made at the land office the uecessary steps will be taken to determine the character of the land before the applicatiou is filed, and in this way expensive and unnecessary litigation averted.

THE Mexican tariff has been chauged recently with a view to protecting the new manufacturing industries of that Republic. The duty on machinery imported into that country has been raised somewhat, which may influence importation of mining machinery to a slight degree. Mining and other machinery are now being made in Mexico, and it is the desire of the Mexican Government to protect their home industries. The duties on wagons, household articles, etc., will have but a small effect on the mining industry. Some months ago a duty on nitro powder was announced to take effect; but this is as yet inoperative, as no powder has yet been made in Mexico.

FROM every section of the mining West comes the news of new finds aud the successful reopeniug of old mines. Although we are still early in the year 1904, the outlook for a prosperous year in the mining industry is very promising. There is little heard at present of labor troubles, though with the coming of summer the fight is likely to be renewed iu several sections. On the whole, the outlook for 1904 is much more promising thau would have been supposed six months ago. The greatest activity is noticeable in the gold and copper producing regions, though other metals are by no means being ueglected.

ACCIDENTS in mines are usually of a novel or unexpected character. It is strange, but a fact, that in performiug extra hazardous work about a mine few men are hurt. This is duc to the fact that the danger is imminent and the necessary precautions arc taken to avert it. Mcn fall into shafts aud are hurt in a great variety of ways that are unanticipated, but when working iu bad grouud every one is alert and on their guard, protecting themselves from falls of rock, or other danger.

Still Room for Improvement.

There is a wide range iu the wages paid miners in the United States, varying from $1.25 or $1.50 per day of ten hours in Tennessee and some of the Atlantic States to $3 and $4 for eight hours in most of the Western States. This difference does not wholly represent the variable efficiency of the labor, for in some of the poorly paid districts the workmen are quite as industrious and as capable as those of the West. The difference in the cost of living, however, in the various sectious goes far toward equalizing the wage rate. In Central America and Mexico native miners are paid $1 to $1.50 per day silver coin of the country, and generally speaking the labor is inferior — that is, what is usually considered skilled labor, such as drilling, timbering, etc. The lower class of unskilled workers are probably as efficient as are fouud elsewhere. While there is no probability of an immediate increase in wages in the metal mines in the Eastern and Southern States, it is not more likely that there will be a material decrease in wages paid labor in the mines of the West. To lower the cost of mining it will be necessary, as in the past, to practice rigid economy, improve existing methods of miniug aud reduction of ores, and to adopt mechanical means to the performance of the work now done by men, as far as economically possible. In this age of advancement, innovation and discovery, it is useless to say that this is no longer possible, as having reached the limit of improvement. There is no more reason to reach such conclusion than there was twenty or even ten years ago. Electricity is one of the most important factors to which we must look for much in the way of reduced expense in both mining and metallurgy, and ten years hence we will doubtless have in successful operation many electric devices iu mining that to-day are unknown and perhaps unthought of.

WHAT the limitation of head will eventually be in hydraulic power plants remains to be determined. In the early days of hydraulic mining, in the desire to reduce the expense of flume and ditch construction, the so-called inverted siphon was introduced whereby water is conveyed from a ditch, flume or reservoir on a hillside across a canyon by means of a pipe, the water having a tendency to rise in the pipe on the opposite side of the canyon, according to the well known principle of physics. At first these siphons were constructed so that the maximum head at the lowest portion of the line did not exceed 250 feet. In 1870 the Spring Valley Water Co. built a siphon in Butte county, Cal., on which the maximum head was 1000 feet. The pipe line supplying Virginia City, Nev., with water had a head of 1720 feet. The Standard Electric Co. of California has a head of 1900 feet at its power house at Electra in Amador county, and now an electric power company in the State of Washington is constructing a pipe line where the head will be 2500 feet, although there is one in Switzerland said to have a head of 3400 feet—equal to a static pressure of 100 atmospheres, or 1500 ponnds per square inch of surface of the pipe. Such installations develop a very high efficiency, but they are also extremely dangerous if a large factor for safety be not provided. Some years ago an engineer making an examination of a pipe line near Sonora, Cal., where the head did not exceed 500 feet, was instantly killed by the bursting of the pipe, from what cause was never known, other than it was too weak to stand the pressure. The danger of streams of water under high head are understood by hydraulic miners.

IT is as important that the mine owner should know the actual value of his mine as the engineer who examiues it with a view to purchase. Guess work and extravagant estimate is no longer permissible with experienced men. It is necessary that facts be submitted, and if no facts are obtainable, then the mine must be developed so that the uecessary information may be had.

ACCORDING to the sworn statements of the several mine managers of the Cœur d'Alene region in Idaho, the lead-silver mines there producecd in 1903 a uet profit of nearly $1,500,000. These statements arc made, as required by the law, to the assessor of Shoshone county, and form the basis of mine taxation, and indicate that the mining industry in that section is prospering.

CONCENTRATES.

A MILLSITE may bo located which has no connection with a mining location. Such a site may bo used for the location of a custom mill.

✣✣✣✣

DACITE is a quartz-bearing varioty of andosito. In it, as woll as in andesite, gold and silver boaring veins occur. Rocks of this typo have mostly been intruded in Tertiary time.

✣✣✣✣

WHEN about to pour molten metal into a mould from a crucible, it is not advisable to have the mould too hot. An overheated mould causes large air vesicles in the lowor portion of the bar.

✣✣✣✣

THE mineral specimen from Copporopolis, Cal., is bituminous rock, probably shale, or clayey matter saturated with bitumen. The bituminous matter is readily soluble in chloroform, but not in water.

✣✣✣✣

BISMUTH (metal) is quotod at $2.10 por pound, subnitrate at $2 por pound and sub-carbonate at $2.25 per pound, Now York City. Bismuth is often accompanied by tin oros, and somotimos by gold and silver.

✣✣✣✣

SOME mines which have made a good record of profitable production so long as they could be worked through modium of a series of tunnols or open cuts cease paying upon the work being carried below the level of the lowest adit.

✣✣✣✣

IN numerous regions laccoliths are accompanied by valuable ore deposits. Noted examples are found at Leadville, at Aspen and in tho San Juan region of Colorado, at Eureka, Nev., and in tho Black Hills, S. D. Laccoliths occur, however, elsewhere, which, as far as known, are not associated with ore deposits.

✣✣✣✣

A MINING PARTNERSHIP is formed when two or more men who own or acquire a mine for the purpose of working it, and extracting the mineral therefrom, actually ongage in such mining operations. Persons jointly conducting a mining enterprise are partners, though there may be no express agreement for such partnership.

✣✣✣✣

THE idea that a fissure vein cannot traverse two adjoining formations (slate and diorite), for the reason that one is of sedimentary origin and the other eruptive, is without foundation. Fissures exist in rocks of all kinds and of all ages, the relative age of adjoining rock masses having no influence on the formation of fissures.

✣✣✣✣

HOISTING ROPES should be examined frequently, and it is a good idea to have a new rope on hand to replace one that is worn. No rope should he used longer than it is known to be absolutely safe. The maximum load does not represent the maximum strain upon a rope. The greatest strain is caused by sudden starting and stopping.

✣✣✣✣

DIFFERENT KINDS of ore require different kinds of screens. A flinty ore which has a tendency to crush into flakes rather than granules requires a slotted screen, not one woven or needle-punched. Granular ore, on the other hand, when crushed will pass more readily through a woven or needle-punched screen than through a slotted one.

✣✣✣✣

ALIENS may locate and hold mining claims under the laws of the United States. The peaceable relocation of a claim taken by an alien (for the reason that such prior locator is an alien) will not inure to tho benefit of the relocator, but it will force the Government to institute the proceedings known as "inquest of office." No one but the Government can set aside an alien's claim.

✣✣✣✣

THERE are a few mincral deposits, but no "veins," in the Hawaiian Islands. The only minerals found there of commercial value are kaolin, sulphur, gypsum and building stone (tuff). Pumice is also found in large quantity in some localities. The kaolin and gypsum are the result of alteration of the volcanic rocks. The sulphur has been and is still being deposited about fumaroles and vents. The mining laws of the United States do not apply on the Hawaiian Islands.

✣✣✣✣

WHERE timbers are scarce or expensive a vein of moderate size with good standing walls may be stoped "on the run" by putting up raises at proper distances and stoping out from the raises, leaving a solid block of ore over the back of the drift. When working up by tbis method only enough ore is drawn out through the mill hole to permit the miners to keep within easy reach of the back of the stope. When the block has been exhausted and the ore all drawn off, the strip of ore over the back of the level may be removed also.

✣✣✣✣

THE rock samples from "W.," Nevada are: No. 1 is trachyte, containing hornblende and mica (biotite); No. 2 is a fine-grained granite rock; No. 3 is felsitic dike rock, in which feldspar is the principal constituent. It contains fine needle-like crystals of mineral, having a metallic luster, which are apparently silver sulphide—the quantity is too small for accurate determination. No. 4 is an amygdaloidal rhyolite, in which the air vesicles are now filled with silica. The silica present is secondary. It contains an abundance of microscopic crystals of magnetito.

✣✣✣✣

THE owner of a mine situated above or at a higher levol than his neighbor may at any time discontinuc work which may result in causing tho water in the idle mine to flood tho lower property. This is the misfortune of tho lower owner, who has no rccourse in such ovont. Whilo operating, mine owners kcep their mincs as free from water as possible, or as free as necessary to the operation of the mine, and this may result in the lower mine having practically no water to handle. The sudden cessation of raising water at the upper mine he cannot prevent, even if it result in also closing his mine.

✣✣✣✣

IF a slag dump contains the ossential elements for forming a suitable fluid slag it has no particular value as a flux, unless the ore charged with the slag also contains the necessary eloments, iron, silica and limo in proper proportion, for if the ore be siliceous theu the slag will be too siliceous. If the ore be calcareous, tben the slag contains too much lime, and if tbe ore be high in iron, the slag will contain too much iron, and in any of these cases an unsuitable slag will result. The slag may be resmelted, however, with a small amount of copper ore and, the copper acting as a carrier, will take up a large percentage of tho gold and silver in the slag.

✣✣✣✣

WHAT is known as the "Dhiel process" in the treatment of gold ores consists of a variety of operations, but is essentially that of sliming the ore, and treating the pulp by a solution of potassium cyande and bromo-cyanide by agitation and filter pressing the sludge, and then precipitating the gold from the solution on zinc shavings. It also includes amalgamation, which may be accomplished before or after the fine grinding of the ore. It is wholly a mechanical and chemical process, the ore being treated raw. It resemblos the Sulman-Teed process, the essential difference being in the precipitation of what is known as zinc "fume" instead of on zinc shavings.

✣✣✣✣

CARNOTITE, which contains uranium oxide, is one of the interesting radium minerals. It is yellowish green in color. That this mineral possesses actinic properties may be demonstrated by placing a piece of metal, such as a coin or key, on a sensitized photographic plate and covering the plate and metal with the powder of carnotite. In twenty-four hours the plate may be developed and a distinct image of the metal will appear on the plate. Carnotite shows no sign of light in the most intense darkness. A large number of minerals contain uranium, but, as far as known, carnotite and pitchblende or uranite are the only ones of commercial importance.

✣✣✣✣

MANY minerals have a tendency upon fine crushing in water to separate from the accompanying minerals and float upon the surface of the water. Graphite, molybdenite, tellurides, gray copper, arsenical iron sulphide, gold, copper and silver minerals are notable examples of this. Often this floating scum is high in gold and silver. It is frequently observed floating on the surface of the water in the settling boxes under concentrating machines. Wherever possible this floating scum should be carried off through a pipe, the lower end of which discharges under water. In some instances it may be necessary to repeat the process several times, a portion being saved from each box.

✣✣✣✣

THE capacity of crushing rolls to reduce rock to fine material depends to a great extent upon the evenness of the faces of the rolls. When the faces become worn unevenly the capacity is greatly reduced. The character of the ore is also important. Rolls should be fed to their full capacity, there being no economy in slack feeding. The modern high-speed roll requires careful attention, and when properly adjusted will give large capacity for power employed, but, it must be remembered, rolls are for pulverizing and are not a rock-breaking device. All rock fed to rolls should be reduced by breakers to small size. No rolls are expected to give high efficiency or satisfaction on coarse rock.

✣✣✣✣

SOME fossils (fisb, wood, etc.) turn to copper, silver-copper and sulphide iron ores, under proper conditions. The most noted instances of this kind are the copper-silver-bearing fish and wood of the permian age, found in Russia, Kansas, Texas and in some other regions where this formation occurs. Sulphide of iron filling casts of fossils is not uncommon in several formations, but rarely, if ever, contain gold or silver in appreciable amount. In the silver mines of Silver Reef, southern Utah, fossilized wood sometimes contained silver. In these mines the silver occurred chiefly in the form of chloride, or as native metal in sandstones and shales. Thero are intrusive rocks in the vicinity.

✣✣✣✣

QUARTZ TAILINGS woigh when dry about 100 pounds per cubic foot (20 cubic feet per ton). Screened tailings, where the grains are approximately the same size, weigh less than where they are of variable size. Where tailings beds are firm, they may be sampled by means of a posthole auger. If they are very dry and run readily, it will be necessary to dig pits and handle larger quantities. The dump should he divided into blocks of regular size and several samples taken in each block, keeping a record of each block separately. As the tailings are removed from the pile in car or wagon, small samples may bo taken of each load by means of a tryor, such as is used in sampling concentrates in sacks. It is made of Russia iron and resembles a buttor tryer.

✣✣✣✣

IN grinding sulphurets for treatmont by the cyanide process, it is considered good practice by some to introduce the cyanide solutions into the barrel where the grinding is being done, as, if subsequontly discharged into an agitating tank, tho sulphides will "pack" almost instantly should any stoppage of tbe machinery occur. Cyaniding in the barrel obviates this contingency. Probably a better practice would bo to crush the ore dry and cyanide in a separato barrel. This would permit the continuous operation of the pulverizing mill and admit of the cyanide barrel being rotated auy desired length of time.

✣✣✣✣

A MINING LOCATION, not patented, is property in the strictest sense of the term and as such is taxablo and subject to sale under execution. In regard to this the Supremo Court of California said, in the case of Meritt vs. Judd: 14 Cal., 60: "From an early period in our State jurisprudence, we have regarded these claims to public mincral lands as titlos. They are so practically. * * * Our courts have given them the recognition of legal estates of freehold; and so, for all practical purposes, if we except some doctrine of abandonmont not perhaps applicable to such estates, unquestionably they are, and we think it would be in harmony with the general judicial system to deny to them the incidents of freehold estates in respect to this matter."

✣✣✣✣

NO PORTION of the Grand Canyon of the Colorado river is in the State of Colorado. The Colorado river is formed by the union of the Green and Grand rivers. The confluence of these streams is in Utah, at tho southernmost point of Grand county. Tbe Grand Canyon begins below the junction of the Rio San Juan with the Colorado. It is 217 miles long and from 3000 to 6000 feet deep. There are mineral deposits in the limestones and quartzites of the Cambrian in tho lower portion of the gorge. These ores are mostly lead, with silver. Gold in the older crystallino rocks is also reported, but none of these deposits are being worked further tban the assessment work necessary to hold them. This is due to their inaccessibility, and it will probably be a long time before the condition will be improved.

✣✣✣✣

WHERE ores are to be sorted by hand almost the only guide to the sorter is the color and luster of the several minerals. In an ore containing copper pyrites, pyrite, zinc blende and galena in a quartz gangue, each man working at the table or traveling belt selects pieces of the same kind of mineral and throws them into a separate box or heap. One is guided by the brassy-yellow of chalcopyrite, another by the bright metallic lead color of the galena, a third by the black or brownish hue of the blende, while the iron and the finely crushed material of all kinds passes along with the belt to be recrushed and concentrated mechanically. By this means several separate products are obtained, and pay received for each according to its value. The zinc is not wanted with either the lead or the copper, and each alone brings a higher price.

✣✣✣✣

IN the development of a mine, crosscuts should always be run into both hanging and foot walls, to ascertain if parallel veins exist. Particularly is this advisable if the rocks adjacent to the vein are soft or show any sign of mineralization. When the crosscut passes from slaty or schistose rocks into hard, granular and unmineralized ground it is usually safe to stop the crosscut, for there is then little hope of finding a vein in the immediate vicinity which is in any way related to the vein upon which the main work is being dono. There are many veins in hard, firm rock showing neither slaty nor schistose structure, even adjoining the vein, and often the ore is "frozen" to the rocks. There then appears no inducement to crosscut. Still, even under these conditions, it is advisable to run drill holes into the walls occasionally to ascertain what the condition in the adjacent walls really is. Neglect to do this has lost valuable ore shoots to the one failing to take this inexpensive precaution.

✣✣✣✣

MANGANESE ORE, occurring in dolomite and containing five ounces silver, could constitute a suitable flux at smelters and might be valuable for that purpose, the silver being paid for separately; but, if no smelter is convenient, it is doubtful if any attempt at concentration would result in commercial success. The various ores of manganese—alabandite (tbe sulphide), pyrolusite and psilomelane (the oxides)—all have a higher specific gravity than dolomite, and, by care after crushing, the ore could he concentrated on tables or belts; but, unless transportation be very low, the ore would have no commercial value for steel making, and, if employed in that industry, the silvor values would be lost. The idea suggests itself that, as the vein is in a region of rich silver-bearing veins, possibly by sinking upon the vein, a better grade of silver ore and less manganese might be found. Many important silver mines contain large amounts of manganese, usually in the form of black oxide at the surface, but as rhodonite (silicate) and rhodochrosite (carbonate) in depth. Alabandite (the sulphide) is rare. High-grade pyrolusite or psilomelane (oxides of manganese) are worth about $20 per ton after being ground fine. It is used in chlorination of gold ores, in glass making and other manufactures.

Schists and Slates as Ore Carriers.

Written for the MINING AND SCIENTIFIC PRESS by ARTHUR LAKES.

I have read with interest the article on "Mica Schist as an Ore Carrier" in the issue of the MINING AND SCIENTIFIC PRESS of February 8, and would like to add my quota derived from experiences principally in Colorado, Wyoming, Arizona, Nevada and North Carolina. It appears to me that some distinction is to be made as to the probable continuity or richness of veins according largely to their particular mode of occurrence and surrounding geological circumstances in schists and slates, some of which, I think, have not been fully brought out in the excellent article referred to.

In entering a region of schists traversed by quartz veins, lenses or ore deposits, it is of primary importance to observe whether, first, the quartz veins or lenses conform exactly both in strike and dip to the bedding or stratification planes of the slates and schists; or, second, whether, though appearing to so conform, they may not really cut the formations at a slight and scarcely perceptible angle differing from that of the strike and dip—i. e., diagonally to them; or, third, whether the quartz bodies or lenses occupy an undoubted true fissure at a large or right angle to the dip and strike of the strata, cutting decidedly across them. In the first case the string of lenses may be strictly of a segregative type, occupying no true fissure, but simply the lenticular openings caused by a gentle corrugation of the strata. Such lenses would, we think, be more uncertain in continuity or ore-bearing than classes number two and three, which occupy true fissures or zones of parting and slipping of the rocks, and come strictly under the definition of true fissure veins. But little difference may appear to the ordinary observer between the outcrops of numbers one and two; but in developing and working downward on lenses containing ore in number two there will be distinct signs of movement and fissuring observed on the walls of the lenses, such as slickensides, brecciated rock, striæ, and other well-known signs of fissuring and faulting movements.

A close examination of the results of deep development and greater experience with these sorts of deposits will show that the lenses, which at the surface may have appeared to exactly conform to the dip and strike of the formation, did not in reality do so, but in extension along the surface diagonally deviated from the true line of strike and correspondingly, or still more so, diagonally in the degree of dip with that of the true dip of the strata or schists. A good example of this is in the Minnie Moore mine at Bellevue, Idaho. A series of quartz lenses carrying large bodies of very rich silver-lead ore occupy a definite zone not far from the contact of a great, overlying mass of intrusive diorite. This mineralized zone can be traced for some miles along the so-called "contact zone," and was assumed by some to conform in dip and strike to the slates along a particular horizon or zone; but by following along the outcrop, and pursuing the vein down in depth, we find the ore-bearing zone materially deviating from both dip and strike of the strata, sometimes the fissure being partly in slates and sometimes partly in limestone intervening between the slates and the diorite, showing clearly that the quartz-zone-lenses occupied a true fissure or true line of movement and parting in the formations, and the ore bodies were not, as some had assumed, "bedded veins" at contact of an intrusive diorite sheet.

Depth in the mine showed ample signs of movement apparently both before and after the vein filling. The ore was usually associated with much brecciated country rock, which, with secondary quartz, it cemented together.

The walls of the ore-bearing lenses were intensely slickensided, and torsional striæ, sometimes in opposite directions, suggested more than one movement having taken place during or after the vein filling. The lenses appeared to be formed (in some cases, at least) by lateral compression and corrugation, as shown at one particular point in the mine known locally as "Cape Horn," where the strata was intensely corrugated into a round, bow-shaped lens.

On the wide space opened by this corrugation there was a notably large body of rich ore found, and in each level where this structure occurred and continued down ore was abundant.

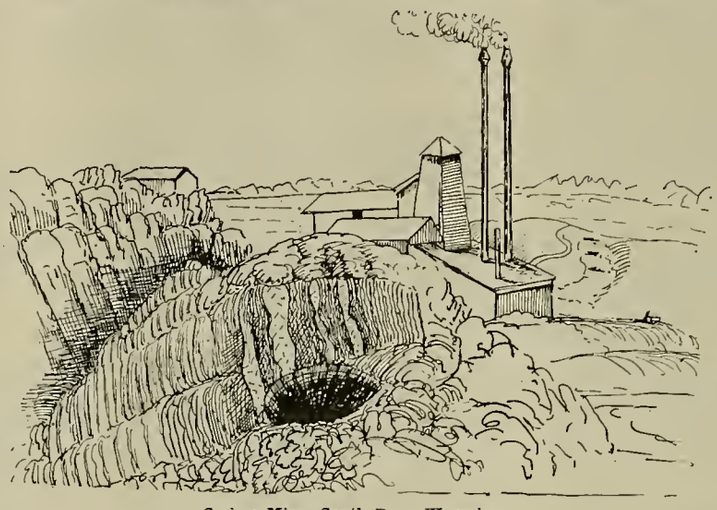
It was worthy of note that immediately after or close to the abrupt end of this corrugation there was a sharp fault indicated by a gulch on the hillside, and by a true fault line and breccia zone in the workings of the mine.

Lens followed lens in depth, and at intervals. At one point and period in the mine's history they seemed temporarily to have lost their cue for discovering the line of lenses by a supposed fault, and, as an illustration of what the article stated, the mine was given up for lost, and abandoned for many years, until other parties took a fresh hold and with a little scientific, common sense development came onto the successive lenses again laterally and in depth.

Experience with this and other mines shows that lenses in slate or schistose formations may occupy true fissures, and in such conditions there is as much reasonable expectation for the vein and ore to keep down in depth as is usually attributed and allowed to so-called "true fissure" veins.

In North Carolina the multitude of ore-bearing lenses that constitute the zones worked there by great open quarries and cuts, while appearing to be

Pegmatite Dikes and Veins in Slates on Sweetwater River, at Base of Wind River Mountains, Wyoming.



Carissa Mine, South Pass, Wyoming.

Lenses Cutting Diagonally Across Schists.

segregative lenses lying conformably with the strata, are found, on close examination, to occupy true slipping or fissure planes, cutting the dip of the strata diagonally at an acute angle, and we believe generally that where these zones of quartz lenses are truly ore-bearing to any important degree they will be often found to occupy true fissured zones, or zone of "discission," parting and slipping.

When schists or slates are violently uptilted, as they commonly are along or in a mountain range, their uptilted condition almost insures actual slipping or fissuring movement or the sliding of one uptilting plane of strata upon one similarly uptilting. Slickensides, even in unaltered sandstone strata, are almost invariably found between the stratification or lamination planes of rocks in such positions, consequently lenses of quartz, either barren or ore-bearing, may reasonably be assumed to occupy true fissures in such formations and under such conditions.

At South Pass City, Wyoming, at the base of the Wind River mountains, there are vast bodies of tilted slates and schists. These are traversed in some places by great, irregular bodies of pegmatite, consisting of coarse, crystalline, orthoclase feldspar, and quartz with comparatively little mica. The greater masses may cut clearly across the dip and strike of the slates and schists, while the smaller, lenticular veins and bodies may conform, or appear to conform, with them. In both conditions near the surface, at least, these veins carry ore.

The Carissa mine at South Pass is on a zone 50 to 100 feet or more wide of vertically tilted schists, the ore occurring in the schists themselves, but more especially in the quartz lenses at intervals between them down in the mine. In some of these lenses there are open "vughs" or cavities containing beautiful, perfect crystals of quartz 8 to 10 inches long by 4 inches wide. Such cavities and such crystals are certainly suggestive of a vein formed in a true fissure and line of slipping and parting that alone could open and keep open cavities large enough for such crystals to gradually form and exist.

In some parts of Arizona, as on Humbug creek, south of Prescott, the country is mostly of evenly bedded schistose rocks and the lenses of quartz lie, to all appearances, in parallel lines, evenly and conformably between the strata. These lenses, like many of the pockets in the California slate region, have proven quite rich to a depth of a few feet, and have been trenched or "chlorided" with profit by the first prospectors. How far the lenses of quartz and the unoxidized ore may keep down remains to be shown by deeper development. It is probable that if in the walls the dip and strike of these veins were carefully noted or followed down they would be found to not strictly conform to the bedding planes or dip or strike of the country, but to occupy true fissuring or parting zones, or, as some have called it, zones of "discission."

In going over a schistose country occupied by these lenticular bodies, a lens of quartz may appear much wider and thicker on the surface than it will be found in depth. Care, also, is to be taken lest by a prominent quartz vein or lens outcropping on the surface, falling over on its side along the strike, its closely parallel ruins may suggest a much wider vein than really exists. We remember a case of such a big quartz vein in the slate region of North Carolina that, measured on the surface, was estimated at 50 feet width. At a few feet in depth it proved to be only 10 feet thick.

Again, an important consideration is as to whether the quartz lenses occur in a region wholly composed of slates or schists, or whether that region is also more or less traversed by eruptive dikes or intrusive sheets, and whether or not there are evidences of more or less disturbance or of intense metamorphic action.

Lenses occurring in a region composed wholly of conformable slates or schists are likely to be lenses of segregation, usually of hard, white, barren quartz, and not liable to be very productive of ore, or, if ore occurs at all, liable to be superficial, pockety and unreliable. There are cases, however, to the contrary.

When these slate regions are traversed by igneous rocks and show signs of great local metamorphic action, such as that changing the slates into sheets of novaculite, or porcellanite, or quartzite, coating the rocks with green epidote, or giving rise to garnets, staurolites and other minerals indicative of strong metamorphic action, when this is also accompanied by abundant signs of faulting and disturbances, we may consider that the geological conditions are favorable for ore occurrences. In such a district, too, it has been observed that the lenticular veins are generally more reliable in character, mineral, size and depth if they are at close contact with the eruptive rocks, than if they are wholly within the slates. Many good mines in Arizona have been developed to considerable depth in veins located at contact of slates and igneous dikes.

In Colorado the schistose or slate element is not so characteristic as in some other regions. In the Gunnison district we have great areas of uptilted schists, probably of Algonkian age. In these there appear to be two or more kinds of ore-bearing quartz veins, some occupying true fissures, like that of the Vulcan mine, in sericite or "silvery mica schists," producing both tellurium, free gold, and gold-bearing pyrite in a gangue of novaculite schists, jasper and chalcedonic quartz. Others, simulating—fissure veins and traversing the country for miles, lying conformably with the strata—appear to be quartzite ledges rather than veins, and are rarely productive.

The white mica (sericite), "silvery" looking schists of this region are often found rich in gold near the vein, and when pounded up "horn spoon" well in free gold.

A remarkable feature of some slates near Wadsworth, Nevada, is that when rubbed together in the dark they emit a strong yellowish glow, resembling phosphorescence. In the Gunnison region numerous large dikes of igneous rock traverse the slate formations.

At the head of Ule creek, in the same region, north of Crested Butte, Treasury mountain is composed of marine Cretaceous shales, metamorphosed into slates. These slates are locally traversed by fissure veins of quartz carrying some ore, but, as is common in fissure veins in such formations, when they cut across the strike and dip they are apt to split up and be scattering both in quartz and ore.

These Gunnison mountains are intensely penetrated by eruptive rocks and evidences of metamorphism are on every side, such as sandstones changed to quartzites, limestones to marble, and shales to slates. It is not surprising, therefore, that ore-bearing veins should occur under such conditions.

A System of Fusing Ores for Assaying.*

Written by Arthur Lachman.

The problem of finding a suitable flux for the ordinary ores met in the practice of assaying is often solved by the assayer upon the "hit-or-miss" principle. The text-books devote scant attention to the subject, or else present such a mass of detail as to be utterly useless. As a usual result, each practicing assayer has his own special "system" of fluxing his ores, which system he guards as a great secret; and to his system he attributes all his own successes, and to the want of it all the failures of his competitors.

Several years ago I was called upon to face a problem more difficult than the fusion of ores, viz., the problem of teaching students to fuse them. For while it is comparatively easy for the instructor to indicate the proper fluxes for each ore, it is a question of months before the student acquires the same facility, and the manipulation of the fire assay becomes an art rather than a science. Under these conditions I developed a scheme for calculating in advance the best flux for any given ore. This scheme was tested in my laboratory with three successive classes, and, as the results were uniformly satisfactory, I feel justified in publishing them herewith.

The General Composition of Ores.—The relative proportions of mineral to matrix may vary enormously; but in the case of ores of gold and silver, which are being considered here, the mineral constitutes but a very small percentage of the ore as brought to light. It is evident, therefore, that in fusing ores of gold and silver we must devote our attention chiefly to the matrix. The matrix is almost always siliceous, often of nearly pure quartz, and may contain, besides the minerals of the precious metals, minerals of other metals as well. The volatile elements of these accompanying minerals are usually removed by roasting, previous to the assay proper. The non-volatile elements in the accompanying minerals are discussed hereafter.

The chemical character of the matrix determines the nature of the flux to be added. Mineralogists are accustomed to classify rocks and minerals as "acid" or "basic," chiefly with reference to the amount of silicic acid present. Thus, granite is an acid rock, basalt a basic rock. This chemical classification is the usual foundation of all fluxing methods and is worked out very simply: An acid rock requires a basic flux, e. g., soda, and a basic rock requires an acid flux, e. g, silica or borax.

The General Composition of Slags.—The object of fusing ores with fluxes is to produce a suitable slag. A slag is a glassy mass, usually and preferably brittle, whose chief virtue is easy fusibility. By proper attention to the composition of the ore, these properties can be readily secured. A fusible slag may be had, first, by adding the necessary elements in suitable proportions; and, second, by providing for the presence of as great a variety of compounds as may be convenient. This latter provision finds its basis in the fact that the melting point of any solid is lowered by the presence of any other substance. It is seldom necessary to make special provision for this, as ores usually contain a considerable variety of elements. The selection of a suitable flux is much more important and is best arrived at by appropriating the experiences of the metallurgist.

Metallurgy performs on a large scale what the assayer endeavors to do in his little crucible, viz., to fuse and slag the worthless matrix or gangue and save the valuable metal. Metallurgists have learned by long and expensive experience to flux their ores with the utmost regard to economy of both fuel and fluxing materials. The silicates showing the best behavior as slags have the following general composition:

Subsilicates	$4M_2O\ SiO_2$	$4NO\ SiO_2$	$4R_2O_3\ SiO_2$
Monosilicates	$2M_2O\ SiO_2$	$2NO\ SiO_2$	$2R_2O_3\ SiO_2$
Bisilicates	$M_2O\ SiO_2$	$NO\ SiO_2$	

where M is a univalent metal, N bivalent, R trivalent. All of the subsilicates are easily fusible; of the monosilicates, those of the alkalies and lead are most fusible; then follow the silicates of iron, calcium, magnesium and aluminum; of the bisilicates, only those of the alkalies and lead fuse readily.

The Calculation of Fluxing Charges.—From the formulæ of the above silicates it will be seen that all siliceous rocks may be assumed to consist of two portions: A fusible silicate and an infusible residue. It is this infusible residue that needs the addition of a flux. For example, trachytes usually average about 60% of silica; they also usually contain sufficient alumina, lime, oxide of iron, soda and potash to form a fusible mass with one-third of the silica; we may, therefore, readily find a flux for trachyte by assuming 60% of it to be fusible, the remaining 40% to consist only of silica.

To make similar calculations for other rocks, it is only necessary to reduce their composition to their "silica equivalent." That this is not a matter of much difficulty will be shown by the following data. In order to fuse pure silica, it is sufficient to form the bisilicate:

$$SiO_2 + Na_2CO_3 = Na_2SiO_3 + CO_2$$
$$SiO_2 + PbO = PbSiO_3.$$

From these equations, one assay-ton of silica will require, in round numbers, the following quantities of flux: Either carbonate of soda, 50 grams; or, oxide of lead, 100 grams. On the principle of having the greatest variety of substances present, the flux for silica (per assay-ton) would consist of 25 grams soda and 50 grams litharge. On applying this principle to trachyte, for example, we find that we may assume it to consist of 40% infusible silica and 60% fusible silicates. Then 40% of an assay-ton of silica would require only 40% of the flux just given. The crucible charge would be: Trachyte, 1 A. T.; soda (40% of 25 grams), 10 grams; litharge (40% of 50 grams), 20 grams.

From this example it will be seen that for each per cent of "infusible" silica it may contain, an assay-ton of ore requires either one-half gram soda or one gram litharge, or any desired proportionate amount of both.

Flux for Limestone.—Limestone, or carbonate of calcium, is the only common rock that calls for the addition of silica in order to fuse it. To form a subsilicate each assay-ton requires four grams silica; for the monosilicate eight grams are required. It is usually preferable to form the subsilicate, as it is much more fusible; but in very complex mixtures the monosilicate will suffice. For lime (CaO) combined in silicates, each per cent per assay-ton calls for 0.08 gram silica to form the subsilicate and for 0.15 gram to form the monosilicate.

Percentage base.	Percentage silica.
One per cent alumina.	0.43 per cent silica.
" " lime.	0.27 " "
" " iron oxide.	0.57 " "
" " sodium oxide.	1.0 " "
" " potassium oxide.	0.67 " "
" " magnesia.	0.36 " "

The application of these figures will be best seen from the detailed calculations below:

Silica equivalent of quartzite.				Silica equivalent of granite.			
Composition—				Composition—			
Silica			77.0	Silica			72.0

Flux for Clay.—The average composition of clay

* Abstract Cal. Journ. Tech.

is 40% silica, 40% alumina and the balauce either fusible or volatile. In forming a fusible subsilicate the alumina takes up 17% silica, leaviug 23% as the "silica equivalent" of clay. In other words, enough flux is added to combine with a weight of silica equivalent to 23% of one assay-ton. This would be either 12 grams soda or 25 grams litharge.

FLUXES FOR IGNEOUS ROCKS.—At this point the fact should be emphasized that it is not necessary to make a full quantitative analysis of an ore before proceeding to fuse it. All of the data give here are based upon the average composition of American rocks as published by the Geological Survey; and, as explained above, the only important item in the composition of a rock is what I have called its "silica equivalent." This factor is calculated below and is quite accurate enough for all the purposes in question.

The flux for any of the above rocks or gangues is ascertained by the simple rule: Multiply the "silica equivalent" by 0.25 gram soda and by 0.50 gram litharge for each assay-ton of ore takeu. It is understood, of course, that fractional parts of a gram may be ignored.

THE USE OF BORAX.—The addition of borax to an assay charge has an important effect ou the fusibility. Not only are the borates quite fusible, but they seem to exert considerable solvent power upon the silicates as well. On the other haud, borax behaves as an acid flux. One gram of borax glass per assay-ton has almost exactly the same effect as 1% of silica; so that if the flux is calculated according to the preceding principles, and borax be added subsequently, the result is likely to be a decrease of fusibility. The best results are obtained by adding a fixed amount of borax, say, 5 or 10 grams per assay-ton, and then using sufficient soda or litharge to neutralize it. Each gram of borax requires ½ gram of soda or 1 gram of litharge.

THE LEAD BUTTON.—The above calculations took no account of the fact that a certain amount of litharge is required to produce a lead button. For my owu work I usually obtain a 20-gram button; this calls for about 25 grams of litharge, which is taken in addition to the amount required for fluxing.

THE FINAL CALCULATION OF ASSAY CHARGES.—The final calculation of fluxes for any given ore is by no meaus as complicated as might appear from the detailed account given above. Multiply the silica equivalent by ½ gram soda and by ½ gram litharge. Add 25 grams litharge for the button; take 10 grams borax and add 2½ grams soda and 5 grams litharge to neutralize it; add a reducing agent, if necessary (starch, flour, charcoal). Charges made in this way may be melted dowu completely in ten or fifteen minutes; the crucible shows no tendeucy whatever to boil over; the crucible walls are uot corroded, so that the same crucible may be used iudefinitely; aud the slag is fluid, usually clear, and always brittle when cold. The use of a salt cover is necessary.

In the event that ores contain more thau one variety of gangue stuff, say, clay and porphyry, it suffices to estimate the ingredients roughly, say, to halves or thirds, to average thc silica equivalent accordingly, aud then proceed as above.

The chief advantage of the above system lies in the saving of time and materials. The charge not only fuses quickly, but a repetition of the fusion becomes unnecessary. The saviug in materials can be best seen by an example: Oue assay-ton of basalt, commonly regarded as difficult to fuse, requires 8 grams soda, 40 grams litharge aud 10 grams borax. According to ordinary methods, at least three times as much flux would be called for. A further advantagc lies in the possibility of using much smallcr crucibles; this increases the furnace capacity and decreases the cost of each assay considerably.

The Zubiate Mines of Mexico.

About 32 miles northeasterly from Hermosillo, Sonora, Mexico, is thc Zubiate mine, which for many years was a producer of silver ore. After years of idleuess it passed into the hands of Americans, who have reopened the mine and equipped it with modern hoisting and reduction machinery. Three and a half years ago the plant burned, but has since been replaced by larger works, better adapted to the treatment of ores which are difficult of treatment by ordinary methods. At present the property is equipped with a large hoist. The 40-stamp mill was rebuilt. It contains also ten pans and five settlers. Beside this there are two rotary dryers, and four rotary roasting furnaces are being put in place. Two dry pulverizers will be added. When fully equipped with the new machinery the mill will have all the essentials of a moderu silver mill. Engravings of the head frame at the main shaft and of the mill are shown on the front page. The shaft has three compartments and is 650 feet deep, being 250 feet lower than the old workings. It is stated that the vein has been drifted for 1000 feet, showing a vein 7 to 8 feet wide. The ore carries lead and silver, with base mineral, which has rendered the ore difficult to amalgamate by the more simple processes of silver milling. D. R. Oliver of San Francisco, Cal., is president.

Mill Screens.

Written by W. H. INCE.*

"For what reason have screens of such mesh been adopted?" is a question which may be very frequently asked, without eliciting a reply. Gold in different gangues requires different methods of treatment, not only with respect to the weight and size of stamps, but also to the mesh of the screen, and it is obvious that the same conditions do not equally apply to quartz, schist, dolomitic feldspar, or other varieties of ore.

The importance of ascertaining whether the mill (wet or dry crushing) is producing the maximum amount of efficient work is self-evident, yet in the majority of cases ignored. The points under discussion may be summed up as follows:

1. In what state does the gold exist in the ore?
(a) Free milling quartz, etc.
(b) Free milling and associated with pyrite.
(c) Free milling and associated with tellurides, sulphides, etc.
(d) Non-free milling.
2. When milled where do the values lie—in the tailrace after passing the plates and conceutrate ores, in the vat sands and residues after treatment, or in the slimes?
3. Practical tests with stamps and screens, guided by preliminary laboratory experiments.

LABORATORY EXPERIMENTS.—Having noted carefully the various grades of pulp from hydraulic classifiers, I have come to the conclusion that ordinary sieve grading is practically useless. With sieving, only account is taken of the actual size of the particles, irrespective of their physical characteristics. Hence, on examining a pulp from mica schist, a considerable quantity of comparatively large mica and quartzose plates passes away in slimes, whereas fine particles (passing through a 100-mesh screen), which in ordinary sieve grading would be counted as slimes, readily settle iu the vats.

The reason is to be found in the varying specific gravities and shape of the particles. Mica in flakes, of specific gravity of 2.6 to 2.9, floats off easily to the settlers, while the small angular grains of pyrites or ironstone (specific gravity 4.9 to 5.2) settle in the classifiers and are caught in the treatment vats.

Some heavier particles, however, are mechanically carried over with the slimes proper, the amount depeuding on the quantity of water, size aud iuclination of the launders, and other influences. Irregular masses of ironstone produced by stamps settle much more rapidly than rounded particles of identical size produced by ball mills or grinding pans. I, therefore, suggest in the examination of battery pulp hydraulic grading as a preliminary, the sands being afterward sieve graded as usual.

THE HYDRAULIC SEPARATOR.—I have found the various forms of apparatus for hydraulic grading used for clay, kaolin and other substances iu the state of fine division adoped in china, porcelain aud allied industries quite inadequate for grading pulp. The well-known Schone's schlammapparatus is clumsy and difficult to regulate. The modifications are expeusive and cumbrous aud unfitted for the requirements of a mine laboratory. The following picce of apparatus I have devised has giveu good constaut results, aud has the advantage of being easily and cheaply coustructed with materials everywhere at hand. The references in the diagram are as follows:

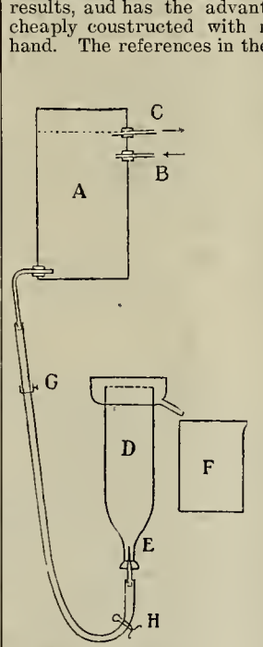

Fig. 1.—Hydraulic Separator.

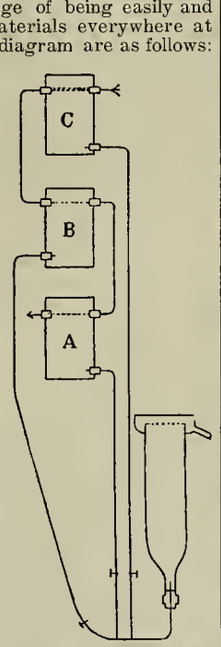

Fig. 2.—Experimental Hydraulic Classifier.

Fig. 1—A. Constant level water tank. B. Water supply from main. C. Overflow. D. Vessel where hydraulic separation takes place. E. Glass tube narrowed to a fine point, leading to reservoir by means of a rubber tube. F. Vessel to catch overflow of slimes. G. Screw clip for adjustment of flow. H. Clip or tap.

The important part of the hydraulic separator is D. It is constructed of a conical glass vessel, which may be made by neatly cutting off the bottom of a white glass bottle which has no shoulder, but sloping sides. Some beer and spirit bottles admirably fulfill these requirements. An arrangement of tin is fixed to the top with white lead to carry off the overflow. In the neck is fitted a cork, through which is passed a glass tube drawn to a fine point to form an upcast in the bottle. The other open end outside the cork is fastened to a piece of rubber tubing connected with the constant level tank. The receptacle F (an 80-ounce beaker) may be provided with an apron in the same way as a settling spitzkasten, but wben workiug on 100–250 grams of pulp this is not necessary, as before the vessel is full the water runs clear from the separator, which indicates the completion of the experiment.

The tank A with constant level may be constructed out of a clean oil drum. It is necessary for comparative experiments always to have the same pressure and volume of water for separation. Under the conditions this is impossible, and no reliance can be placed on results obtained with varying flow and pressure of water. The velocity of flow must be adjusted to the quality of the ore treated and the method employed on the works for separating sands and slimes. I found that with a 3-foot level of water a flow obtained by adjusting the clip G so that 250 c.c. of water passed through a ½-inch orifice of E in the hydraulic separator per minute was sufficicnt. Where hydraulic separation on the works obtain, this quantity would probably have to be increased.

A comparison by careful panning of the slimes from the mill (after separatiou) with the slimes from the experimental separator will determine the required flow of water. Constant flow is of the greatest importance for the same series, and should be determined so that, if through accident or negligence the screw clip has been altered, the original flow may be rcascertained. Increased flow results in decreased percentage of sands.

Having constructed and adjusted the apparatus, the experiment consists in allowing the water to rise in the hydraulic separator till it is about half full, and thcn adding 100 grams of the dried pulp, which bas been broken up, to avoid lumps of slime, by passing through a 20-mesh sieve and the water allowed to run till clear, with partially slime-free samples, such as vat sands. The quantity may be increased to 250 grams. The residual sand is theu washed on a vacuum filter, dried and weighed. The slime is treatcd in the same way. It is not advisable to take the slime by difference, but by actual weight, to check results.

RESULTS OBTAINED.—After obtaining a series of results from a battcry employing a 28 screen, ten head were set apart fitted with a 32 screen for experimental purposes. For the sake of comparison and conciseness both series are placed together.

A. TAILRACE SAMPLES.—The total pulp, after passing the plates and the concentrators, was subjected to the ordinary sieve grading, for the sake of comparison, with the following results:

		28 SCREEN— %	28 SCREEN— Assay.	32 SCREEN— %	32 SCREEN— Assay.
Remaining on..	60	19.4	7.12	12.2	6.12
	80	19.5	6.12	22.4	6.12
	100	33.7	4.12	19.0	4.12
Passing through.	100	26.2	4.8	46.2	4.6

The apparent rise of slimes (portion passing through 100-mesh) and the high assay value may here be noted. As the ordinary sieve grading does not represent the sand and slimes as separated in the vats, a preliminary hydraulic grading in my apparatus detailed above was undertaken.

HYDRAULIC GRADING.

28 SCREEN.

	%	%	%	%	Assay.
*Sands	33.5	34.4	48.5	41.0	9.12
Slimes	66.5	65.6	51.5	59.0	2.6

32 SCREEN.

	%	%	%	%	Assay

Passing through	100	45.1	46.2	6.6	6.6

It will be noticed that the values tend to increase

*Mining Journal.

* The figures represent averages of different samples taken on different occasions, such representing a 24-hours' run.

with the coarseness of the sand, with one exception, where the values were evenly distributed. As might be expected, the alteration of screen has little influence on the percentage of slimes proper (i. e., hydraulicly separated, as distinct from mechanical sieve-graded slimes).

Fine gritty quartz, pyrites, or diorite, though passing with ease through a 100-mesh screen, leach readily, and by employing adequate separators, preferably graded spitzluten (hydraulic separators) may be retained in the vats. The slimes eliminated consist of clay, talcose and kaolin-like substances, and should be free from gritty particles. Where imperfect separation obtains, canvas tables may supply the deficiency. It may be here noted the slimes separated on the works averaged 2 dwts., those obtained from sieve grading about 4 dwts., and those from the experimental hydraulic grading 2 dwts.

The general distribution of the gold throughout the various grades having been ascertained, it became a matter of some importance to determine whether the gold was in the quartz (quartzose shale) or the pyrites gangue, and if in the latter, whether it was enclosed or disseminated. To this end the sulphurt in the sulphides was estimated in the various grades, and assay sample ground to pass an 80-mesh sieve, and panned off in the ordinary manner. This invariably resulted in showing considerable quantities of free gold but little pyrites in the coarser sand, the proportion of the constituents beiug reversed as the sands become finer; the finest saud, passing through the 100-mesh sieve, showed comparatively large quantities of pyrites and no free gold.

This confirmed the results of the sulphur estimations, the percentage of active sulphur in FeS_2, increasing with the decrease of the size of the particles. The sand passing through the 100-mesh screen consistently showed double the percentage of active sulphur than the sample remaiuing ou the 60-mesh sieve.

From these figures we may safely conclude that in the coarser sand the gold is present enclosed in quartz or similar matrix, where in the fiuer sand it is associated with pyrites. In the particular ore under discussion, owing to its action with cyanide and its microscopical character, the gold was probably disseminated through the pyrites, and not simply enclosed. Estimations of iron threw no light on the location of gold in the ore, though they confirmed the gradual decrease of non-ferruginous gangue with the increase of size, but bore no direct ratio to the sulphur.

ESTIMATION OF IRON AS FE_2O_3.

Remaining on	60	5.544	2.38	3.782
	80	6.664	3.64	3 933
	100	6.412	3.178	4.321
Passing through	100	6.888	4.018	5.731

The figures of the sulphur results can only he accepted as approximations, as the barium sulphate results are never, except by chance, absolutely accurate. The large variations observable in one sample from another are due to the greater or less oxidized ore passing through the mill. In all cases a sample represents an average of twenty-four hours. The percentage of sulphur multiplied by two gives roughly the percentage of pyrites.

‡B. Vat Sands.—The same procedure was adopted with the vat sands as with the pulp from the tailrace. Teu head of battery were fitted with 32-mesh screens. The tonuage of ore, percentage of extraction from the plates, and sands were carefully compared and noted. The following figures represent the comparison of results obtained with the 28 and 32 screens from vat sands before and after treatment:

28 SCREEN.

		%	%	Assay—

	100	11.6	8.7	8.6	6.12
Passing through	100	42.5	35.0	8.6	7.0

† It is quite useless to determine the total sulphur, as frequently (especially in the Kalgoorlie belt) sulphates in the form of gypsum and heavy spar are present in the ores, and do not usually form a matrix for the gold particles. Vide my paper on "Notes on the Cyanide Process for Extracting Gold," Chamber of Mines of Western Australia, July, 1902.

‡ These results were all obtained from 150 tons of sand before and after treatment, not from small lots cyanided in the laboratory.

It will be noted that with finer crushing the percentage of fine sand passing through the 100-mesh is slightly increased, but the general extractiou remains practically unaffected. The loss of sulphur in the treated residue after cyaniding is marked, and may throw some light on the cyanicide action of pyrites. Probably the occasional presence of thiocyanate may be due to this cause, and not, as originally supposed, from the reduction of sulphates.

Conclusion.—By the foregoing series of experiments, carried out on the small scale in the laboratory, and subsequently with a 10-head battery, it has been shown that the values lie in the coarser particles of ore both in the pulp, vat sands and residues. One would naturally anticipate that with finer crushing a greater extractiou would result, especially as in the heavier masses of quartz the gold was shown to be free milling, and probably a higher extraction in the cyauide vats would be obtained.

Unfortuuately, the figures representing the results of the cyanide extraction remain practically the same for both screeus:

Assays—	Charge.	Residue.	Average Ore Milled.
28-Screen	7.3	2.2	18.5
32-Screen	7.2	2.1	19.8

The plate extraction showed only a slight increase—approximately, 1 dwt. per ton. It is not advisable, however, to increase the extraction by a small percentage when the amount milled is decreased in such proportion as to uegative the appareut better results. The decrease of tonnage milled in this particular instance came to over 100 tons for an average month (fifty stamps), which the extra gain in amalgam did not compensate. The figures, however, were useful as a guide to future treatment. A glance at some of the averages already quoted shows that the high values in the cyanide residues lie always in the coarser sand.

	Assay Values. 60.	80.	100.	Passing 100.
Charge	12.12	11. 0	8. 6	8.6
Residue	4 12	3. 0	1.12	1.9
Charge	8. 6	0.12	6.12	7.0
Residue	4. 0	3.12	1. 6	2.0

These could be arrested before they come to the vats by a more efficient method of concentration. If it were found impracticable to catch them on a vanner or other mechanical concentrator, they could be easily separated in a hydraulic classifier; in fact, I am of opinion the most satisfactory method of cyaniding sands seems to be careful classificatiou, the coarsest particles beiug returned to some sort of grinding or amalgamating pan and the rest of the pulp distributed according to size in separate vats and receiving separate treatment. Why should sand which will extract and leach in a few days be mixed with pulp which takes weeks to satisfactorily treat? To couclude, although in this particular instance the original screens were adhered to, it was, nevertheless, satisfactory to kuow from actual experimeut that, as far as the milling was concerned, the screens adopted were the most advantageous, and the data obtained pointed out the necessary modifications conuected with the treatment of the pulp after leaving the plates.

The work in connection with this paper was carried out in the laboratory of the Sons of Gwalia gold mine, and I have to thank the courtesy of W. J. Loring for the permission to use the figures quoted.

Appendix.—The same apparatus may be used for experimenting with the hydraulic classifier. For this either varying volumes or pressures are required, but so arranged that at each stage a definite volume or pressure is obtained. This may be accomplished by keeping the screw clip G always the same, but varying the pressure by means of three or more constant level tanks at various levels, say, 3, 6, and 9 feet from the level of the liquid in D (Fig. 1). In this way the pulp would be separated into four grades. The apparatus modified to serve as a hydraulic classifier is shown in Fig. 2. A, the lowest level, turned on would give slime at the discharge, B turned on would wash out the next lighter particles, whilst the residue iu the separator, after the third carries nothing more away, would consist of the coarsest gold-bearing sand fit for a grinding pan. It must be borne in mind that the pressure of water is dependent, not on its bulk, but on the difference of level.

No tunnel or other mine excavation may lawfully be run under the surface of land belonging to another without his consent, except in the case of the privileges granted by the extralateral right law.

The Limitations of the Cyanide Process.*

Written by H. T. Durant.

Speaking geuerally it may be stated that it has almost become an axiom that the surface equipmeut of a gold or gold-silver mine is not complete without a cyanide plant.

This is no doubt, in part, due to the success attending the Witwatersrand plants, and these have been extensively copied in various places, where sometimes at least local couditions and the varying natures of the ores hardly permit such, or any, cyanide plant to be profitable.

It may be very broadly stated that ores which are amenable to auy method of cyanide treatment fall naturally into two classes:

(1) Those iu which the gold is carried mainly in the mineralized portion of the ore.

(2) Those in which the gold is carried free in quartz or other gangue.

The first class includes all ores in which payable values are carried in iron, copper, or arsenical pyrites, tellurides, etc., or the oxidization products of one or more of these minerals, and this class permits of a wide range of treatment, varying according to special circumstances.

There may also be ores intermediate between these two classes, such as the Witwatersrand ores.

It is, however, principally with ores of the second class that the few remarks in these notes deal.

There are, in Rhodesia, several properties in which the ore is a fairly clean quartz, very slightly mineralized, the mineralized portion being poor in values and represeuting considerably less than 1% by weight of the ore.

Such ores when milled yield values to the plates which are proportional to the fineness of the product from the mill.

If the gold in the ore is fairly coarse the values in the mill tailings are usually such that, after milling with, say, a 700 screen, apparently the mill tailings might at first sight be neglected as regards further treatment, at least on small propositions.

On the other hand, if the gold is very fine, even by increasing the battery screen up to even 1600, the tailings will still be found to be a valuable asset.

But whatever values may be in the tailings, it is found that the values extracted by cyanide are such as would in all cases entail an unsatisfactory residue, and in most cases would mean that the cyanide plaut would be run at a very small profit, and this would especially be the case on small properties, where the working expenses per ton would naturally be relatively high.

There is fairly conclusive evidence that the unsatisfactory extractions by cyanide mentioned above are due to the fact that the major portion of the gold passing the plates is locked up in the gangue, and therefore not accessible to cyanide solutions, or conversely, that when the ore is crushed fine enough to expose or free the gold that very nearly all the values are caught on the plates; in other words, such ores are free milling propositions in the fullest sense of the term.

The following tables show the results of actual work in the mill of the Guinea Fowl mine; these results were obtained, for confirmatory purposes, soon after the starting of the mill, practically identical results having been obtained experimentally before the starting of the mill:

TABLE I.—WET CLASSIFICATION OF TAILINGS FROM GUINEA FOWL MILL.

Size of Material.	Percentage	Assay value dwts. fine gold per ton.	Representing dwts. fine gold per ton of tailings
Staying on 3600 screen (square measure)	22.5	11.00	2.475
Passing 3600 screen (square measure), staying on 6400 screen (square measure)	12.0	6.00	.720
Passing 6400 screen (square measure)	65.5	1.50	.982
Assay value of tailings by calculation from constituents			4.177 dwts.

The tailings under consideration in the preceding table, when assayed as a whole, were found to carry 4 dwts. of fine gold per ton (short).

It is seen that while slightly over 4 dwts. of fine gold are in each ton of tailings that 3.195 dwts., or nearly 80% of the total values, are carried in less than 35% of the total tonnage.

In other words, it is in this case merely necessary to take out by any simple sizing arrangement that portion of the tailings which fails to pass a 6400 square measure screen, and one will then have obtained from each 100 tons of 4 dwt. tailings 34.5 tons of tailings going 9.2 dwts. fine gold per ton, leaving 65.5 tons of tailings carrying 1.5 dwts. gold per ton, and these are more or less valueless according to local conditions.

The table below shows wet classification of tailings from another mill. The tailings, though very low in

* Jour. Chem., Met. and Min. Soc., S. A.

value, still well illustrate the values of the various sizes in the mill product.

TABLE II.

Size and Description of Material.	Percentage	Assay value dwts. fine gold per ton.	Representing dwts. fine gold per ton of tailings .....
Finer concentrates panned from portion of tailings passing 2500 screen (square measure)	4.13	4.00	.165
Coarse sand (including coarser concentrates (staying on 2500 screen (square measure).....	25.90	2.80	.725
Fine sands and slimes passing 2500 screen (square measure).....	69.80	.85	.594
Experimental error	.17	.....	.....
Assay value of tailings by calculation from constituents			.1.484 dwts.

NOTES ON TABLE II. — These tailings, assaying practically 1.50 dwts. fine gold per ton, are seen to carry .89 dwt. or 60% of their total values in 30% of their total tonnage; that is to say, that every 100 tons of 1.5 dwts. tailings will yield thirty tons tailings, assaying slightly less than 3 dwts. per ton.

It has been stated before that the total tailings mentioned either in Table I or Table II, or any of the constituents of either tailings, yield unsatisfactory extraction by cyanide; similarly it has beeu proved that any of the constituents on crushing finer, yield to plate amalgamation and also to cyanide solutions gold in proportion to the fineness of the crushing.

In the case of tailings mentioned in Table II it is clear that it would be good procedure to mill with a coarser screen, so that, while increasing the stamp duty, the oversize taken out from the tailings for recrushing and further amalgamation should be of a higher gold value.

The writer is acquainted with at least one case in which fine crushing of the whole ore followed by amalgamation yields exactly the same results, as regards recovery of gold, as coarser crushing with amalgamation followed by cyanide plant for the sands. Iu such case it is merely a question of capital expenditure and total working costs to determine which method to adopt; on the other hand, in the case of ores mentioned in preceding tables there could be no question of cyanide plant unless after fine crushing it were cheaper to treat by cyanide thau to run over plates.

Instances of this kind could, if necessary, be multiplied. It would appear that when an ore, after crushing and amalgamation, yields slimes which do not pay to treat, it is good practice to increase the percentage of these slimes as much as possible while still keeping the value of the slimes below the paying point; such procedure is co-related to the well-known milling practice of Califoruia and Gilpin county, Colorado.

Without intending to discuss iu these few uotes the question of milling in its most modern aspects, it may be taken for grauted that any exceptionally fine crushing would not usually be carried out in a stamp battery.

The Silver City, Idaho, Geologic Folio.

Precious metals and opals are sufficient to make almost any area attractive to man. They are the most important mineral resources of Silver City quadrangle, which has recently been topographically and geologically surveyed by the United States Geological Survey. A geologic folio (No. 104) descriptive of the quadrangle, which is the work of W. Lindgren, N. F. Drake and F. C. Schrader, is now available and may be procured for 25 cents on application to the Director of the United States Geological Survey, Washington, D. C.

The Silver City quadrangle is situated in the southwestern part of Idaho, south of the Snake River plains, close to the Oregon boundary line. It includes the northern end of Owyhee range and a part of the sloping high plains bordering it on the east and west.

Silver City, the county seat of Owyhee county, is located in the southern part of the quadrangle and has a population of about 600. A few miles west of Silver City is the town of De Lamar, and a small place, Dewey, is located about half way between them.

The principal industry of the district is gold and silver mining, which has been carried on successfully since 1863 in the vicinity of Silver City and De Lamar.

The larger part of the rocks of this quadrangle do not contain fissure veins or other metalliferous deposits of any kind. As indicated by the placer gold found in Succor creek, a gold-bearing area occurs somewhere near its head, but the primary deposits have not thus far beeu located.

Along the southern boundary of the quadrangle there is a mining district of small extent, but of great importance. The deposits are located on both sides of Jordan creek, on War Eagle mountain, Florida mountain and near De Lamar. They were discovered in 1863, and have yielded a total of over $30,000,000, of which amount approximately $12,000,000 is in gold and $18,000,000 in silver. The output of the War Eagle veins from 1863 to 1878 was about $15,000,000. After an interval of twelve years the De Lamar veins came into bonanza in 1890, and in seven years produced $6,000,000, mostly in gold. About 1892 the deposits on Florida mountain began to be exploited and now overshadow the De Lamar mines in output. The production in 1900 was nearly $776,000 in gold and 1,000,000 ounces in silver. The process used to recover the gold and silver from the ores is ordinarily that of pau amalgamation. In late years the cyanide process has also been used to treat low-grade ores and tailings.

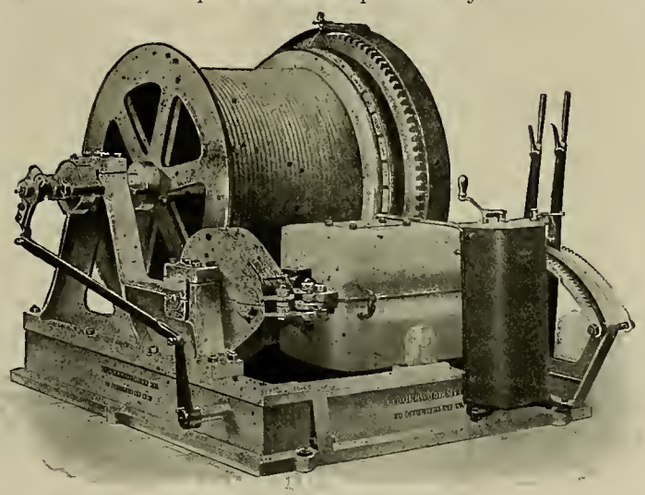
Snake river contains, in this quadrangle, as it does all through the Snake River valley, a considerable amount of gold in its sandy gravel bars. The gold is extremely fine and flaky, containg about 1000 colors to the cent. During many years from several hundred to $1000 worth of fine gold was annually washed from the streams in this quadrangle, but at present very little work is done and then only at intervals.

Opals have been found at various places in the uorthern end of the Owyhee range. They are usually in the abundant vesicular cavities of the eruptive basalts and rhyolites. Some good fire opals have been reported, but by far the larger quantity is the common opal, of no value.

Direct Current Electric Mining Hoist.

Herewith is illustrated a direct current electric mining hoist built by the Lidgerwood Mfg. Co., 96 Liberty St., New York City. This hoist is designed for use with a direct current of 500 or 250 volts.

The drum motor and controller are mounted complete on a bedplate. The resistauce boxes are usually separate from the hoist, being conveniently located so that the heat generated may not be annoying to the operator. In smaller sizes it is sometimes desired to have the machine completely self-contained and portable, in which case the resistances are of special form and attached to the inside of the bedplate. The friction drum is of the standard Lidgerwood form. The motor, which is made by the General Electric Co., is of the armored type and especially designed for hoisting purposes; the moving parts protected from dust and moisture by suitable casing; the gearing from the motor to intermediate shaft is cut, and enclosed in an oiltight gear case. The drum gearing is cast from standard patterns and is protected by means of the usual guard band. The coutroller, which is of the railway type, is provided with a reversing switch and mounted so as to be most convenient for the operator. The friction and brake levers are mounted in a rack with notched quadrants and are fitted with thumb latches.



Direct Current Electric Mining Hoist.

A New Metal.

Another uew metal is reported, which in many of its properties is similar to aluminum, but still of lesser weight. It was discovered by the French engineer, Albert Nodon, and is called "nodium," after him, says Uuited States Consul Guenther of Frankfort, Germany. It is manufactured by electric process. In color, luster and structure it is like steel. Its specific gravity when molten is 2.4. Its resistance against breaking is given as about 20 pounds per square of 0.04 inch. Its constancy in the air is higher than that of aluminum. Its ductility is between 6 and 8 inches; the malleability can be compared to that of bronze. It melts at about 600° C. It is suitable for being cast into forms. The conductibility for the electric current is said to be as high as that of copper of equal weight. If natural power—especially water power—can be used for its manufacture, the cost in round figures is about 15 cents per pound. The discoverer predicts numerous uses of nodium in the near future, especially for electric wires and cables, for light but strong parts of motor cars, torpedo boats, men-of-war, street cars, military outfits, airships, etc., and for castings in plate bronze, German silver and similar metals.

Some Features of Mining Operations in the Homestake Mine, Lead, South Dakota.

NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS by BRUCE C. YATES, E. M.*

STOPING.—During the year from June, 1902, to June, 1903, 1,279,000 tons of ore were milled by the Homestake Milling Co. Approximately 80% of this was mined on the different levels from the 100-foot to the 1100-foot. The remainder came from open cuts and from "draw raises," by means of which, as will be explained later, the ore left in the roof of old stopes is drawn out.

OPEN CUTS.—The ore obtained from the open cuts is broken down from the sides into openings that connect with the regular levels of the mine. These openings or raises are provided with chutes on the different levels from which the cars are loaded. The loaded cars are made up into trains of from four to eight cars, according to the grade of track, and hauled to the shaft by horses.

The ore taken from open cuts is mined very cheaply. Two miners, whose wages are $3.50 per day, will break, on the average, 200 tons in one shift. Two men are employed at the chutes, oue to break the rock at the grizzlies and one to load the car. The grizzlies are located two or three floors above the chute. If the haul is long two horses with two drivers are required to haul the ore to the shaft. The cost per ton of mining and delivering to the shaft is as follows:

Two miners at $3.50	$ 7 00
One grizzly man at $3.50	3 50
One chute drawer at $3	3 00
Two drivers at $3	6 00
Two horses at 90 cents	1 80
Blacksmith labor	50
Explosives, $0.026 per ton	5 20
Total	$27 00
Cost per ton	13½

Ore and waste are blasted down together and the waste is sorted at the chute and used for filling.

In one of the open cuts now being worked the process of mining is much like the work of making a very deep cut through a hill some 300 feet high. Tracks are laid from the crushers to one end of the cut and the rock is blasted down, loaded into cars and trammed directly to the crushers.

ROBBING OLD WORKINGS.—The pillars aud backs of old stopes which were left in place in the older workings of the mine are now being removed by a system of draw raises. A description of the method of attack may be of interest to many who are face to face with the problem of robbing old workings in vertical formations.

It is very important to know the exact location of these pillars and roofs before starting this system. If the maps and stope records have been faithfully kept this becomes an easy matter; otherwise the memory of some old employe must be depended upon to give the necessary iuformation.

Having located the ore, a "nine-post raise," which consists of four regular stope sets arranged in a square, is put up either on the foot wall or on the hanging wall side, preferably the foot wall. This raise is carried up a sufficient height to reach the ore above the waste filling. Grizzlies are put in on the floor next to the top and the sides of the raise are carefully lagged to protect the men. The run of ore is then started by ablast or by barring. A man stationed at the grizzly breaks the rock so that it will pass through into the chute which is located on the sill floor.

The timber required to make a nine-post raise four floors high is—36 posts, 24 caps, 24 ties, about 150 lagging, 4 stope ladders, and one ordinary board chute. The grizzlies are made by placing two or three 12-inch timbers, spaced 12 inches apart, over oue set of timbers and protecting these by pieces of sheet iron curved to fit. The posts on the top floor may be protected in a similar manuer from the blasts and from running rocks. (See Fig. 16.)

Sixteen thousand tons of ore were taken from one raise in six months; and this was done in a place where vain attempts had been made to reach the ore by carrying up timbered stopes through the old fill.

Should the ore be too solid to run the raise will serve as a manway to a timbered stope started on top of the fill.

Whenever a run of waste is encountered it is drawn down and used for filling in other parts of the mine, and the ore from upper levels will follow the waste down.

TERRA CAVING SYSTEM.—Stoping without timbers

*Copyrighted.

was carried on in the Deadwood-Terra mine, which is now a part of the consolidated Homestake, for a number of years prior to the time when the Homestake assumed control.

A crosscut from the shaft cuts the ledge which was opened from wall to wall throughout the entire length. All the ore was removed from the sill floor excavation. As soon as the ledge was sufficiently developed a drift was driven in the footwall approximately parallel and about 20 feet from the ore, and openings made from the drift into the ore chamber at convenient intervals. The ore was then broken down and the surplus removed through these openings. As the miners used the broken ore as a staging to work on, only about 40% of the ore could be removed until the stope was finished.

The stopes worked by this method are from 30 feet to 50 feet wide and the dip of the ledge is 75%.

Stoping may be carried on on several levels at the same time, provided sufficient back is left in between levels. When the level above is finished this back may be caved and all the rock removed on the level below.

No timber is required other than a few lagging for staging, but the method is not applicable to wide ledges.

Fig. 17 shows a cross-section of several levels and a part plan of one level showing the method of operation.

Square Set Timbering.—Until within the last two years all stopes in the Homestake and Highland mines were timbered by the square set method. An enormous amount of timber was required to timber the excavations, and the work of handling the timber through the shafts made it difficult to hoist sufficient ore to supply 900 stamps.

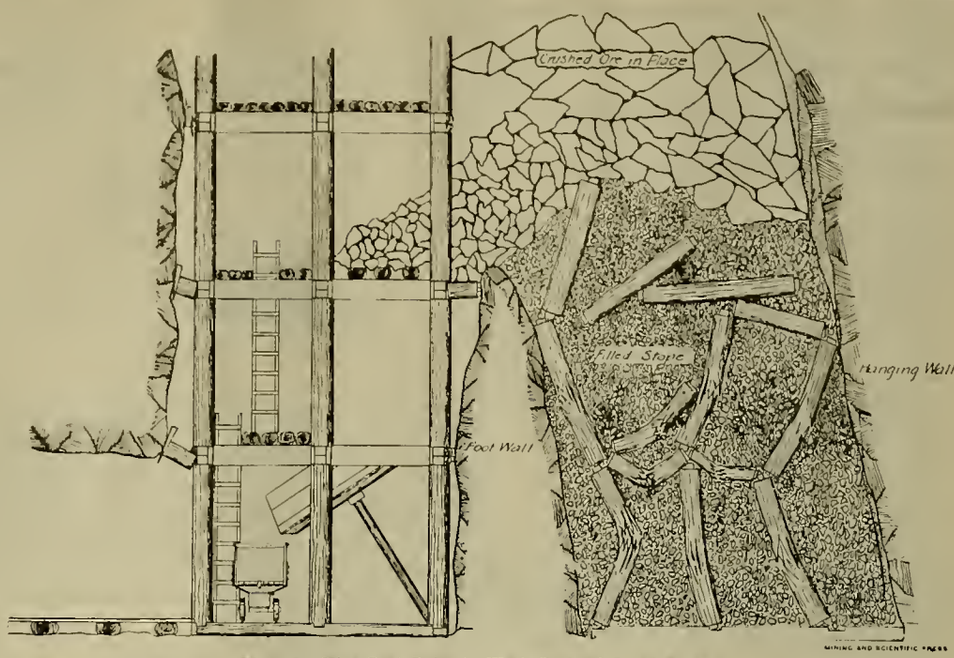


Fig. 16.—Nine Post Raise to Work Back of Caved Stope.

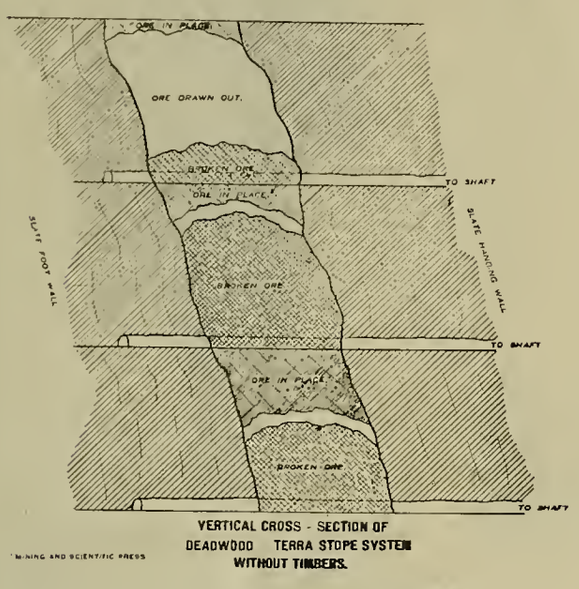
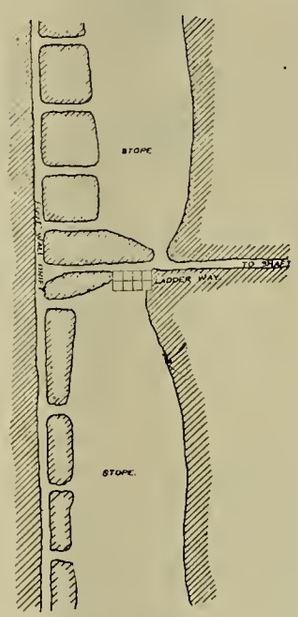


VERTICAL CROSS - SECTION OF DEADWOOD TERRA STOPE SYSTEM WITHOUT TIMBERS.



HORIZONTAL SECTION.

Fig. 17.

No unusual features are introduced in this method of timbering, so that no detailed description will be given. The sets are 6 feet square, sill floors are 9 feet high, and all upper floor sets 8 feet 5½ inches. A sill floor set contains 324 cubic feet, or about 32 tons, and an upper floor set 304.5 cubic feet, or 30 tons.*

All stope timbers are shipped in convenient lengths to the company's sawmill, which is located at the Golden Prospect shaft. Here they are sawed and framed as needed. Most of the timber used is native, although some Oregon timber is used for caps and ties.

With labor at $3 per day, it has been found that the framing of what is termed a set of timbers (a post, a cap and a tie), costs 60 cents, and the cost for sawing lagging is 5 cents per running foot.

Two timbermen, whose wages are $3.50 and $3, working one shift, will stand timbers, build chutes and do all necessary repairing in a stope which furnishes 100 tons of ore in twenty-four hours. This makes the cost of labor for standing the timbers 6½ cents per ton.

All chutes are the ordinary board type, with bottoms made of lagging and sides of 2-inch plank. The rock is held back by two boards, one above, but not directly above the other. Fig. 18 is an isometric drawing of a stope chute.

On the upper levels of the mine, where the ledge was broken and comparatively narrow, the sill floor excavation was made from wall to wall and sometimes for the entire length. The sill floor timbers were then put in and stopes worked where convenient. When the ledge began to widen this method proved disastrous and thousands of feet of lumber were used to make bulkheads in a vain endeavor to keep the stopes open.

*It is usually estimated that 13 cubic feet of rock in place equal one ton. This would make about 23 tons per upper set.—Ed.

A new method was inaugurated on the 600-foot level under the supervision of W. S. O'Brien, mine foreman, which is being used on all new levels. The plan is as follows: A crosscut is driven through the ledge from the central shaft which is called the main crosscut. The ore body is then developed by driving a 24-foot drift along the foot wall. From this drift rooms 60 feet wide are opened across the ledge with 60-foot pillars between each stope. Beginning with the main crosscut a pillar is left on each side, then a 60-foot room, a 60-foot pillar, and so on to the end of the ore body. These rooms and pillars are numbered north and south of the main crosscut. No. 3 stope north would be the third stope north of the crosscut, and No. 4 stope south the fourth stope south of the crosscut.

Some difficulty was experienced in keeping the sides of the rooms straight while the sill floor was being opened. To overcome this sills were laid in the foot wall drift to lines given by the surveyor, and the miners took their lines from these. Each stope contains eleven lines of sills. When the system once became established no difficulty was experienced in keeping the room of uniform width and the sides comparatively straight.

When a stope has been worked and filled the pillar may be attacked and by lacing the sides next the fil all the pillar may be removed.

(To be continued.)

An adverse claim to be effectual for the purposes contemplated by law must be filed prior to the expiration of the sixty-day period of publication of the application notice. Such publication is simply a notice that such application has been made.

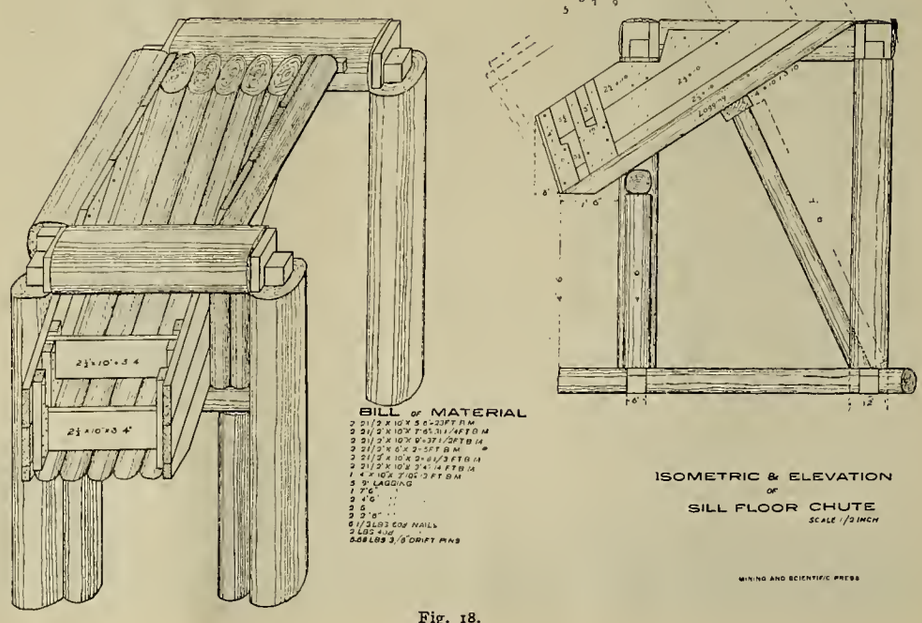


Fig. 18.

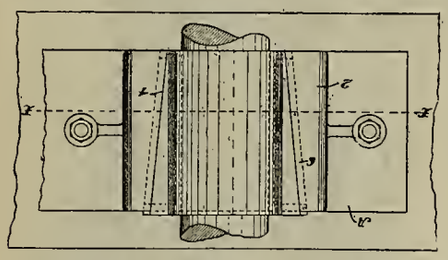
Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 23, 1904.

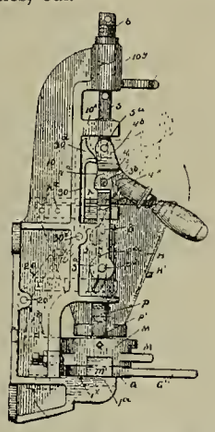
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

BATTERY STEM GUIDE.—No. 752,349; W. H. Martin, Nevada City, and A. McCombie, Grass Valley, Cal.



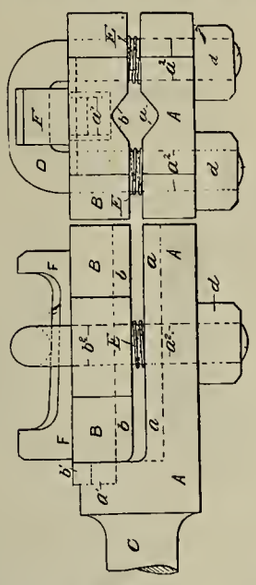
Battery guide comprising metallic block having upon opposite sides of its stem space downwardly converging guides, and cap having lateral flanges, edges of which converge downwardly and are adapted to engage guides.

CUPEL MAKING MACHINE.—No. 753,121; A. C. Calkins, Los Angeles, Cal.



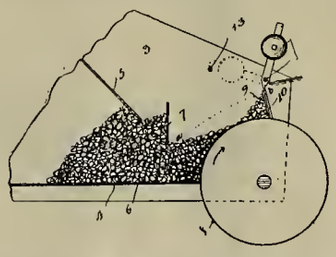
Cupel making machine, comprising main frame, feed hopper, reciprocating plunger mounted on main frame, two-part mold swingable alternately under hopper and plunger, and comprising upper member having vertical aperture or cell, lower solid body that forms false bottom for cell, upper and lower portions having interengaging members, whereby two can be moved in unison, and means for supporting upper and lower members for movement independent of each other, and means for imparting compressing movement to plunger.

CHUCK FOR ROCK DRILLING MACHINES.—No. 752,972; J. Hodge, Witwatersrand Gold Fields, Transvaal.



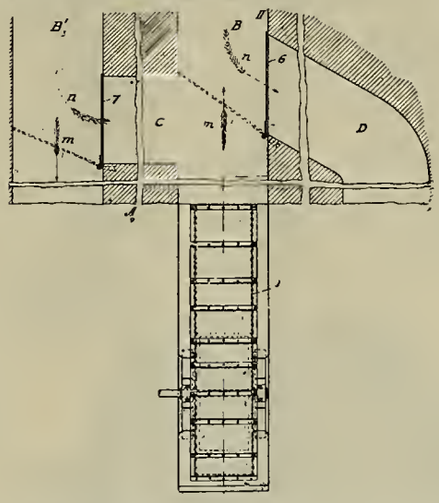
In rock drill chuck head or body constructed in two parts longitudinally, one part being provided with projection and other part with corresponding groove or recess to receive projection, in such manner that two parts of head may be expanded to receive shank of drill, and means for compressing two parts of head to secure drill.

GATE FOR ORE POCKETS OR SIMILAR RECEPTACLES.—No. 753,076; F. K. Hoover & A. J. Mason, Chicago, Ill.



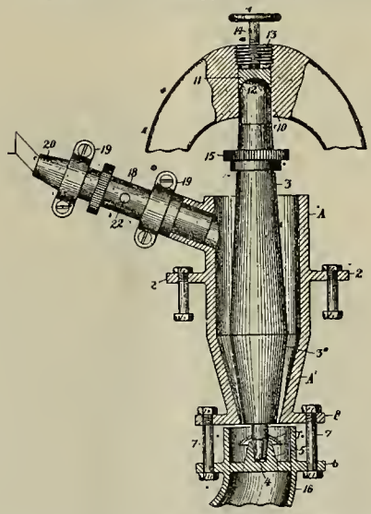
The combination with pocket or hopper having discharge roller mounted across discharging end, of pivoted gate in nature of guard mounted above and parallel with discharging surface of roller, and controling means connected with pivot of gate serving to hold the latter stationary in both its fully open and closed positions, but permitting gate to pass from closed to open position under impact of material thereagainst when roller is operated.

MINE VENTILATION SYSTEM AND APPARATUS.—No. 752,955; W. Clifford, Jeannette, Pa.



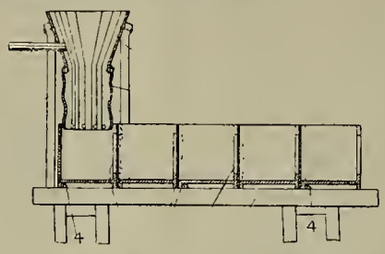
In mine having plurality of entries, drift or drifts connecting entries, and drift connecting one of entries with open air, combination of fan adapted to impel current of air through the mine, and movable doors placed at points of communication between entries and drifts, adapted when in one position to allow current to circulate through mine in one direction and when in another position to allow current to circulate in another direction and out through drift to open air.

ROCK BREAKER AND PULVERIZER.—No. 752,945; D. D. Bailey aud J. O. Bailey, Banner, Cal.



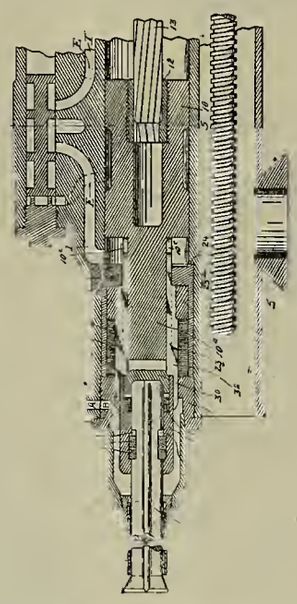
Crusher and pulverizer consisting of shell, upper portion of which is cylindrical, lower portion convergent, crusher consisting of upper cone divergent downwardly, and lower cone convergent downwardly, bases of cones being contiguous, feed-chute connecting with cylindrical portion of shell at point below top thereof, step and spindle forming journal for lower cone, and cap within which upper end of upper cone is turnable, and screws by which step and cap are vertically adjustable.

RECIPROCATORY GOLD SEPARATOR.—No. 752,926; J. P. Schmitz, San Francisco, Cal.



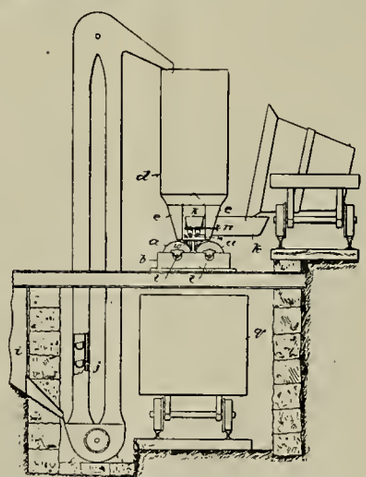
Improved gold separator comprising flat smooth table inclined in directiou of its length, and having stops or abutments along sides; inclined trough of equal diameter throughout aud consisting of segmental sections abutting endwise, each of sections having flange at one end which projects both above and below bottom of section and flange at opposite end which projects below only, each of outwardly extending flanges forming rockers for section; transversely disposed stops on table engaged by rockers to prevent end movement of trough; packing strips between abutting sections; meaus for oscillating trough; and lugs on outer sidcs of trough and adapted to contact with abutments at end only of each transverse oscillation of trough.

ROCK DRILLING MACHINE.—No. 752,819; S. W. Brothers, Denver, Colo.



In rock drilling machine, combination with casing and reciprocating piston therein, of drill holding chuck, and means for connecting pistou and chuck whereby they rotate together, but have independent longitudinal movement, means comprising detachable keys mounted in seats formed in chuck and cngaging seats or grooves formed iu piston.

ORE AGGLUTINIZING APPARATUS.—No. 752,726; E. A. Uehling, Passaic, N. J.



* In ore agglutinizing apparatus, combination of two co-operating rolls, means for rotating rolls, means for feeding ore to rolls and means for feeding slag to rolls, together with means for regulating supply of ore and slag.

Mining Summary.

Specially Compiled and Reported for the Mining and Scientific Press.

ALASKA.

E. B. McFarland of Portland, Or., and a company of Portland and Idaho men have taken over the Petty group of mines, 70 miles from Skagway, for $100,000. They will start operations this month with H. T. Gager as manager. The mines are on the White Pass and Yukon rivers, in Tagish Lake district, and are readily accessible. The ore is gold and silver, with traces of copper and lead.

ARIZONA.

Cochise County.

The Tombstone Con. M. Co. at Tombstone is operating at four different shafts below the water level. The four points are the main shaft, the Emerald, the West Side and Silver Thread. At the two latter placos—which are some 50 feet below the old water level—ore is being extracted and shipped, while at the main shaft a drift is being run at the 700-foot level, 100 feet below the water line, toward the Contention and Grand Central ledges. This drift is in 120 feet. At the Emerald the incline shaft is below the water line and will be sunk to the first station, when drifting will be started toward the ore zone. The distance between the Silver Thread on the north and the Emerald on the south is 1¼ mile. The pumps in the main shaft are sending up 2,000,000 gallons daily to the surface. The four-compartment shaft is being continued to the 1000-foot level. Three carloads of ore are being shipped daily to El Paso, Texas, and 100 tons per day is being shipped from the Lucky Cuss dumps. The latter dump contained 12,000 tons of ore, which was contracted for by the smelter company.

Graham County.

The Stevens C. Co., near Clifton, last week closed down temporarily, awaiting the arrival of air drills and boiler for the pumping plant. The company will put in an air plant. Manager Alsdorf expects the company will resume work by April 1.

The Shannon C. Co. at Clifton is entering on its second year as a producer and it is expected the second section of the concentrator will be in full operation next month, which will mean a production for the year 1904 of 12,000,000 pounds of copper, at a cost, it is claimed, of 8 cents per pound. The company employs 400 men, owns its own stores, dwellings and a hospital, besides concentrator and smelting plant. Last week the company produced 150 tons of copper.

The Arizona C. Co.'s report for the year ended September 30, 1903, and submitted February 15, 1904, shows that during that year they made out of their smelting and other profits $1,600,000, and during the last half year 209,150 tons of ore were treated, yielding an average of 3.28% copper. Of this, 194,238 tons were concentrating ore, yielding an average of 2.51% copper. The production, as well as profits, was curtailed by the strike of the miners last June. The mines are at Clifton, adjacent to the properties of the Shannon C. Co. and the Detroit C. Co. The company produced 30,000,000 pounds of copper in 1903 at a cost of 7 cents a pound. It employs 1500 men and has 4000 acres of mining ground.

Maricopa County.

(Special Correspondence).—A. Anderson is preparing to ship silver-lead ore from Morristown to the smelter.——The Arizona M. & D. Co. have completed a road from the Hassayampa river to the Montezuma lead mine. Men have been at work cleaning out the Montezuma shaft so that work can be started in the mine this month.

The Vulture Development Co. has taken over the Angel mine, near Wickenburg. The company is not connected with the Vulture mine, but will operate properties in that district.——C. P. Pierson expects to put men to work on his copper claim, near Morristown. Shipping ore is on the dump. —— H. Herlick of Phœnix has bought the H. J. Bennett copper group, 12 miles east of Morristown.

G. Hamlin of the Relief mine reports opening up free gold-bearing diorite in the west drift of the mine.——C. M. Love of Chicago, Ill., president of the New Vulture M. Co., says the Vulture mine will have development increased and other work done.——C. Feihls, assayer for the White Tanks M. Co., which owns the Wickenburg smelter, says they are arranging for full operations.——G. Carguile is working claims in Cave Creek district. The ore is free milling.

Wickenburg, Feb. 29.

C. M. Love of Chicago, Ill., president of the New Vulture M. Co., which owns the Vulture mine, near Wickenburg, is arranging to resume operations.

Mohave County.

(Special Correspondence). — Considerable activity is manifested in the Leland-Gold Road district. The Mohave G. M. Co. at Leland has completed a narrow gauge railway from the east bank of the Colorado river, opposite Needles, to its Leland mine, a distance of 17 miles (as the Mohave & Milltown Railroad), and on this line, 7 miles above the river, is the 40-stamp mill of the company, which has completed its first month's run. It is handling three tons per stamp daily, and water is pumped 2½ miles and stored in a cement-lined reservoir. The railroad grades vary from 3½% to 6%. Oil is used for fuel. The company has twenty steel ore cars of five tons capacity used in hauling the ore, which runs $15 per ton. About ninety men are on the payroll at the mine, working in three shifts. The ledge runs directly over the top of a steep, cone-shaped hill, and on this the company is running tunnels from both sides. On the south side three are being driven, on the north two, to connect with the two upper ones on the opposite side. Two hundred feet are yet to be driven to connect the upper drifts and 900 feet to connect the lower. All this work is in payable ore. On the south a tramway leads from the mine to the chutes. The Vivian mine, which has promising ore bodies, is near the Leland.

One mile east of Snowball is the German-American group, with hoists on the Pioneer and the Treadwell. At present no work is being done on this property. The Treadwell is equipped with electric power buildings and other facilities. This property covers an extension of the Leland ledge. Other properties in the camp are the Teddy Roosevelt, owned by W. A. Brooks, and several in Silver creek, 4 miles distant, owned and operated by D. Slocum, Black Mountain G. M. Co., M. Miller et al.

Five miles by stage from Leland is the Gold Road mine, Acme postoffice. A year ago a mill of 120 tons capacity was put in operation. It is a dry crushing process. Owing to heavy expense of operating, stops are being taken toward replacing it with the wet process. Sixteen cyanide tanks are in use and values are extracted to 85%. Three cleanups a month are made, giving an average of about 1400 ounces gold bullion each, valued at $18,000. The group, consisting of fourteen claims, is owned by a close corporation, of which O. P. Posey is president. The ledge runs the length of three claims. On its western extreme the company is sinking a shaft, now down to 400-foot level, and the vein has been crosscut for 19 feet, with the hanging wall not reached. The 10 feet next the foot wall averages $20 per ton. The remainder runs $5 per ton and for the present will not be removed. The surface cropping of the ledge along the canyon east of the shaft has been found to carry values. Thirteen hundred feet of this was leased in sections of 100 feet each, and considerable work is being done there. Some of the leasers are taking out high-grade ore. It is quarried off the face of the ledge and sorted. The first-class is being shipped to smelters and the other is worked at the company's mill. The company mills the ore for $5 per ton, guarantees 80% extraction, pays $16 per ounce for the gold and receives 30% of the net product. The vein is a fissure in a porphyry dike 400 feet wide, and on the surface is mineralized for length of 1500 feet. The company works sixty men in two shifts in the mine proper, and is using three electric and three air drills. Another compressor will be put in and air drills used entirely. The ore from the shaft is dumped directly into a gyratory crusher and reduced to hen's egg size, then passes down a chute to a tunnel connecting with the surface from the 50-foot level, and is received into cars which tram it to the mill, passing through a system of crushers until it is carried to the cyanide tanks. The mill is constructed in four units, each of which runs independently of the others. Water is brought 4 miles from Little Meadows, on the Kingman road, and it is thought can be developed in sufficient quantity for operating a wet mill. Water is coming into the mine also in considerable quantities. J. D. Spargo is manager, and has mapped out a general plan along which future work will be prosecuted.

Acme, Feb. 27.

(Special Correspondence).—F. Tofty reports making a strike of lead-silver in the hills west of the Minnesota.——The Minnesota M. Co. has its steam hoist in place for sinking on the Manzanita.

F. Ferguson & Son have the shaft on the Redemption mine down 100 feet, and are taking out $40 gold and copper ore.——The Samoa mine, owned by the Chloride G. M. Co., is sacking high-grade shipping ore.

The Lucky Boy mine suspended operations last week indefinitely.——Superintendent J. H. Pyne says he will have the wagon road to the Roger Boy mine completed by the 15th inst. ——F. Mitchell has crosscut into a body of gold-silver ore on the Last Dollar.

The Midnight mine has a 30-foot ledge of milling ore on the 200-foot level.——S. Rhea has completed a 200-foot contract of drifting on the Gem mine at Corbat.

The Chloride G. M. Co., operating the Paymaster mine, in Todd basin, under lease and bond, is making shipments of ore.——J. Carroll has opened up silver ore on his claim, west of the Juno mine, near Chloride. —— The Maguire mine, near Kingman, is inactive at present, but will resume this month.

The shaft on the Dompsey & O'Dea gold mine at Pilgrim, near Chloride, is down 103 feet, and is shipping gold ore.

The Great West mine, in Weaver district, will have its crushers and cyanide plant in operation April 1.——The Virginia mine and 10-stamp mill in Weaver district is temporarily closed down, pending arrival of additional machinery.

J. Prisk has resumed work on the Pastime mine in Mineral Park district, with a small vein of shipping ore in sight.

Chloride, Feb. 9.

(Special Correspondence).—For the past year little work has been done in Chloride district. However, the prospects are for renewed activity the coming year. It is said there are by actual count between Chloride and Kingman eighty-five claims that have produced not less than $10,000 each, some from $50,000 to $500,000, yet the deepest working in the entire district is but 570 feet down. Two drawbacks to Chloride district have been incompetent management and the fact that the ore is refractory.

Recently the Minnesota-Connor group was taken over by the Chloride M. & D. Co., controlled by Griffith & Rigbter, under lease and bond, and next week its mill will again be running. This mill has a capacity of 250 tons per day, which will be increased. The first work will be to run through a tailings dump of 27,000 tons, at the same time sinking on the main shaft to develop the ore body and, incidentally, more water. The ore is an arsenical iron sulphide, carrying some copper and zinc, a little lead, and principally gold and silver, the concentrates running $60 per ton. The mill is run by a 235 H. P. Corliss engine and ligbted, as also the mine, by electricity. From the Minnesota-Connor shaft, with a 72° incline, the ore is elevated to a 300-ton ore chute and automatically dumped. Thence it passes through a Blake crusher, a Dodge crusher, two sets of rolls, then elevated to the trommels, three sizes, and the coarse size goes to another set of rolls. From the trommels the ore goes to two concentrating tables, and through automatic classifiers to other tables, of which there are nine in all, and to a mill for finer grinding. The slimes are concentrated on four Frue vanners. Settling tanks save the slimes and water, so that not more than 2000 gallons of water used in milling is actually lost per day. Concentrates are handled by gravity and conveyed to a drying platform, from which they are hauled to the station, 2 miles, and shipped. Formerly jigs were used in the concentrating process. It is proposed to install a cyaniding plant. A reservoir is built on the hill above the mill. D. G. Jewett, superintendent, states that he will have in mine and mill about forty men at work.

Nearer Chloride the Elkhart mine and mill will resume operations the coming month. It has been taken over by J. H. McNeil of Los Angeles, Cal., with A. C. Moorhead as manager, as the Security M. & Dev. Co. Preparations are being made to work the tailings over and the shaft, down 500 feet, will be sunk 500 feet more. There has been a total of 6000 feet of development in this mine since 1897, but it has been idle for a year. Mine and tailings work will be first done, but the mill will not be put in operation as yet. The ore is a lead sulphide carrying gold and silver values.

Between the Elkhart and the Minnesota-Connor is the Tennessee mine and mill.

On the slopes of Suhrum's peak in Cerbat range, 4 miles east of Chloride, are Samoa and Lucky Boy mines that have kept up steady shipments of high-grade ore. The former is under bond to L. Hoffman and the latter to F. H. Stull and J. P. Finegan, with C. Richard in charge. The ore averages $45 per ton and cost of shipping and smelting amounts to $15 per ton. The Samoa is taking out high-grade ore and doing additional development. On the 180-foot level in one stope the vein is showing 18 to 24 inches in width. It carries high perceutage of silver with gold values.

Other prospects in the vicinity include the Roger Boy, owned by E. Pyne; the Pay Roll, of J. M. Murphy; the Rainbow, of A. M. McDuffie, the Sunshine, J. Barry: the Altata, owned by a Chicago, Ill., company; the Midnight, K. St. Charles; the Pinkham: the Schuylkill, W. D. O'Neill and others.

At Mineral Park little work is being done. The town was recently partly destroyed by fire. Near it the turquoise mine is being worked by a few men. Nearer Cerbat the Paymaster mine is again being opened up, and the ore shoot which was lost has been again found and is being worked. It is under bond to L. Hoffman and is superintended by T. Stinson. This mine's deepest workings are down 200 feet.

At Stockton Hill the C. O. D. mine, owned by the Tagggart Mercantile Co., is being unwatered.——W. A. Mensch, of the Enterprise M. Co., 18 miles east of Kingman, reports favorable prospects. Drifting on the 200-foot level last week opened up a water channel and the water rose 45 feet in the shaft. He is working twelve men and reports concentrates running $144 per ton. The ore is mainly copper sulphide, carrying gold, silver and lead values. The vein crops 30 feet wide on the surface. The group consists of twenty claims.

The Great West mine, 35 miles northwest of Chloride, owned by Eastern men, is being operated, with T. McGraw as superintendent.

On the other side of Kingman, on Burro creek, the Monmouth M. & D. Co. is working. It is headed by J. P. Wallace. The ledge is showing for 3000 feet in length, 40 feet wide, and unassorted runs $2 to $8 per ton. It is 75 miles southeast of Kingman, in the foothills of the Aquarius mountains. Development is progressing.

The O'Dea & Dempsey group, 10 miles west of Chloride, is the only free-milling proposition in this section at present in operation. Some development work is being done by the owners. The property is still held at the option of the Marquette Exploration Co. of Chicago, Ill., for $250,000. The ledge crops for 1600 feet and is 40 feet wide, dipping west at an angle of 30°. It is on the lower slope of a high hill, into which it dips. The vein is irregular, as far as uncovered, showing unbroken hanging wall of porphyry. The foot wall is also porphyry, but not the same as the hanging. The ore taken out is being piled on the dump, no steps having been taken as yet to ship or mill it. Free gold can be seen in the rock. There are four shafts with a total of 250 feet of work.——Two miles from the Dempsey-O'Dea are the Azalia claims, owned by Brown, Pettit & Carey. Little development has as yet been done.

Chloride, Feb. 27.

The company organized to take over the Hunrath mines, near Silver Creek, in San Francisco district, near Acme, will put men to work on the mines next month. ——R. Zuver has opened up a group of mines in the Silver Creek section, San Francisco district, which is showing ore. R. J. Holmes is part owner. They have men at work taking out ore.

Pima County.

(Special Correspondence).—To the Imperial Copper M. Co.'s property a branch road is being constructed from Red Rock station, on the Southern Pacific Railroad, a distance of 23 miles. Grant Bros. are the contractors. The work began to-day.

Tucson, Feb. 23.

Yavapai County.

Stukey Bros., who took over the Dixie 10-stamp mill at Walker, and have overhauled the plant, started crushing ore last week. They have men at work on the Everhart and Eureka claims of the Sheldon group and have a large amount of ore on the dump ready to be milled.

Considerable mining machinery is reported going in on properties tributary to Prescott. The Oro Grande M. Co., north of Wickenburg, is putting in 8000 feet of 4-inch pipe, and C. W. Platt, superintendent of the Illizonia M. Co., near Prescott, is putting in a 20 H. P. gasoline hoist, air compressor and drills.

Superintendent F. E. Jordan, of the properties of the Great Republic G. M. Co., on lower Turkey creek, 2 miles below Turkey station, on the Prescott & Eastern railroad, says the new hoisting plant has been put in place and development work will be increased before the company starts to take out and ship ore.——The Cash mill in Hassayampa district, near Prescott, is in full operation and fifty men are at work.

T. Wilkinson of Burlington, Iowa, of the Oro-Cobre M. Co., which has claims in Copper Basin section, near Prescott, has bought twelve adjoining claims to this group. He has put men to work on development. The number will be increased and machinery added.

The Pittsburg-Jerome C. & G. M. Co., organized by Pittsburg, Pa., men, to develop a group in Jerome copper belt, will sink a 500-foot shaft at the head of Mescal guloh, south of the United Verde mines.

CALIFORNIA.

Amador County.

Machinery is going in on the Dead Wood mine for Kimball Bros., at Defender. They have water to contend with, but have a steam pump in operation, and report making good headway sinking.—— J. B. Dille has been running a tunnel on the Kankakee and has tapped his ledge at depth. He is taking out ore.

At the Shenandoah mine, near Plymouth, a shoot of ore with gold values has been struck in the north drift, says Superintendent Thornton. —— Superintendent Worthing of the Bay State mine has put in an assaying laboratory. He is increasing work at the Bay State, working several levels, and keeps the 10-stamp mill steadily in operation.

The mill at the Bunker Hill mine, near Amador City, is in full operation.

W. J. McGee, a director in the Central Eureka M. Co. at Sutter Creek, says the contractors finished sinking 100 feet from the 2100-foot level sump last week. The contract price was $12.50 per foot, with $100 as a premium if the 100 feet were completed in twenty days. The shaft went into hard quartz and Superintendent Thomas extended the premium limit to twenty-three days, within which the work was finished. The nine contractors netted $5.50 per day per man. The company furnished all material except powder, fuse and caps. The mill was kept going to full capacity—5000 tons per month—during sinking. The same contractors have taken another 100 feet to sink on the same terms.

It is reported the Thorpe mine at Fourth Crossing will be reopened.——The owners of the Reilly Ranch mining property on the Calaveras river, near San Andreas, are arranging for working it by dredging.

The Ophir M. Co. has made final payment on the Lloyd mine on Central hill, near San Andreas, and will increase operations there. In the Reed mine the incline shaft has reached the ledge.

At the Argonaut mine, at Jackson, with forty-five men at work, progress is being made. The Argonaut is operated by shaft, total depth of which is 2230 feet. It is equipped with double reel hoist, run by water power, capable of hoisting three tons of rock 3000 feet, at rate of 600 feet per minute, says the Record. There is also a 40-stamp mill on the ground as yet idle. While some attention is being given to cleaning out drifts, which were formerly worked, the principal work is prospecting. After completion of repairs to the shaft, a station was cut at the 1600-foot level and drifts started north and south. In the meantime the north drift at the 1570 level has been driven and is in 220 feet; miners are cleaning out the north and south drifts at the 1460 level. The mine is being unwatered as rapidly as necessity for use of the lower workings appears. The water is below the 1800-foot level, where at 1810 feet a station is being cut. J. B. Francis is superintendent.

At the Zeila mine, near Jackson, the usual number of men are at work in the mine and mill. The Zeila treats all its product at the mine, there being, in addition to the 40-stamp mill, a chlorination plant for treatment of the concentrates. At present the entire work underground is devoted to exhaustion of the ore bodies uncovered, says the Record. No new development is being done in the mine.

Butte County.

The Big Butte M. Co. has bought more mining land on Butte creek, adjoining their original claim, near Forest Ranch, and is increasing its working force.

Calaveras County.

At the Stockton Hill mine at Mokelumne Hill the additional three stamps began dropping last week, making six stamps in operation.

The Oriole mine was closed down last week, says the Angels Record. —— The diamond drill is still being used at the Sultana mine. —— The Wilber-Womble mine at Hodson is temporarily closed down. —— It is reported the Angels mine at Angels will this month start an addition of sixty stamps to its forty stamps now in operation. —— Work was started last week at the Carson Hill mine at Irvine, south of Angels. —— A drift will be run on the 700-foot level of the Angels mine to the Sultana 700 level to make an air passage between the two mines.

The '49 M. Co., operating at Douglas Flat, has struck the pay gravel channel. Another shaft has been sunk west of the hoisting works. Levels were run and it was there the strike was made. A hoist will be put up and they will develop the west end as well as the east end.

Ore has been opened up at one of the Hercules-Horseshoe group of mines at Indian creek, near Murphys. E. Delray, superintendent, says there is a shoot of 12 feet in length of rich quartz. There is an arrastra and also a small mill on the mine and crushing will be started this month.

The San Andreas Gold Channel M. Co. has been incorporated by W. H. Miller and J. L. Flanagan of Sacramento and F. J. Juchter et al. of San Andreas, to work the Chris Anderson gravel mine on the Central Hill blue gravel lead near San Andreas. Juchter has a working bond on the Chris Anderson mine. They will start work this week. A 10 H. P. gas engine and a double-action sinking pump, capable of raising 9000 gallons of water per hour from the bottom of the shaft, will be put in. The shaft is down 85 feet and will be sunk to bedrock, which is thought to be 15 feet farther.

El Dorado County.

Superintendent Voorheis of the Lew Wallace group of mines near San Andreas is arranging for the summer's work on mines near El Dorado owned by himself and C. F. Walter.

Placerville reports say a mill will be built at the Slap Jack Flat mine in Dark Canyon, near Placerville.

Fresno County.

The California Oil Fields (Ltd.) has another well at Coalinga down in the oil sand waiting to be perforated. This well increases number of producing wells to seventeen. A 2000-barrel tank has also been added to its storage capacity. On a knoll west of the rigs a 2000-barrel water tank has been built.

Kern County.

The Karma M. Co. mill at Mojave is in operation.——The Queen Esther mine and mill are in full operation.

S. J. Montgomery and D. J. McCormick have located the Ophir tunnel site near El Paso, 8 miles northeast of Randsburg. They expect to run a 200-foot tunnel. A 6-foot ledge has been uncovered which is said to assay 32 ounces silver and 30% lead.

Nevada County.

The compressor at the Mountaineer mine, near Nevada City, is in place and development will be increased. The electric motor for the air compressor is being set up.——The cable used in transmitting electricity to the pump on the 750-foot level of the Brunswick mine, near Grass Valley, has been replaced with a larger one.

Operations will be resumed at the New Eureka mine at Canada hill, near Grass Valley, the suspension being temporary, due to storms.——When work is resumed at Shady Creek, near Nevada City, in the spring, Manager F. H. Hall will put in a heavier pump and make other improvements.

The Brunswick mine, near Grass Valley, will resume full operations this month, says Manager Mallon.

The Buckeye mine, near Nevada City, has suspended operations until completion of the 10-stamp mill.——The air compressor of the Murchie mine is in operation and the number of underground men has been increased. The mill will begin crushing this week.

G. W. Manwell, superintendent of the Black Swan drift gravel mine of Mooney Flat, near Nevada City, says the cave that occurred there recently has been cleared and work resumed. The dirt caved in the main drift for a distance of 25 feet, from the surface down.

C. Christopher, superintendent of the Peabody mine, near Grass Valley, expects to reopen the mine.

The mill at the Spanish Ridge mine (formerly the 16 to 1) above Washington is running, says Superintendent Egan.

Operations at the Canfield placer mine on Shady creek, near Nevada City, are temporarily suspended on account of high water in the creek. The bed of the creek was being worked, says Superintendent W. Graham.

The California mine, on Deadman's Flat, near Grass Valley, has been bonded to G. R. Tuttle. Work will start in the spring. The claim embraces ninety acres, most of which is patented. The mine is equipped with hoisting and pumping plant and a 5-stamp mill.

Placer County.

The Rawhide quartz mine on the American river, near Shady Run, near Towle, has been sold to the Soldan G. M. Co. of San Francisco, with H. W. Morris as manager. The company will put in an air compressor, and as soon as the weather is settled enough to handle machinery will add ten more stamps to the mill. Twenty men will be put to work this week.

Riverside County.

F. James, T. H. Whitaker et al. of Los Angeles have organized the Pinon Con. M. Co. to develop a group in Pinon mining district, 15 miles north of Indio. Development machinery and a mill and cyanide plant will be put in.

Santa Barbara County.

The Western Union Oil Co., near Santa Barbara, is drilling three wells on the Careaga property and the drills will not be stopped at usual depth of 1700 or 1800 feet, but will go to depth of 3600 feet, with expectation of striking the lower oil sand. The Western Union wells are averaging 150 barrels a day.

Shasta County.

The Yellow Jacket, Keno, Maud, Amy, Jay Bird, Imperial, Pine Crag, West Eureka, Dorothea and Josephine quartz claims in Backbone district, near Redding, have been consolidated by the owners, R. M. Saeltzer, R. E. Corrigan, and J. S. Smithson, as the Graves Con. group of mines.——The Summit Con. group of mines has been organized, comprising the Maine, Yankee, Iowa, Oregon, Texas, Keystone, Avery and McHugh quartz claims in the Backbone mining district. The owners are M. E. Dittmar, G. F. Graves, C. Avery and M. Lindley.

The Mount Shasta mine on Clear Creek has been shut down temporarily pending reorganization of the company, as the Phœnix Con. M. Co.

A company has been incorporated in San Francisco to develop the five claims of the Little Bully Hill group, near De Lamar, with J. O'B. Reddin president, and H. L. Paddock, D. Byron, W. Haines, C. E. Anderson and R. C. Wilson. The last named is superintendent. A shaft is being sunk to 200 feet.

The Midas M. Co. has suspended operations at Harrison gulch owing to objections of the union men to working with a non-union man put on by Superintendent Oswald. The men are "locked out." The pumps are kept running.

Sierra County.

The Plumbago mine at Alleghany is closed down until the flume that carries the water to the power house can be repaired. The high water of the Middle Yuba last week took 50 feet of the flume away.

As a result of the unusually heavy rain storm of last week, work in the Oriental mine at Alleghany is discontinued temporarily, says Manager M. W. Mather. The bridge which conveyed the Oriental pipe line across the Middle Yuba river was carried away by the high water. The bridge was 80 feet in length and 6 feet from the bottom of the river. The pipe line furnished water that generated power for the Oriental mine, the machinery being in the Plumbago power house.

Siskiyou County.

It is reported J. Johnston of New York, secretary and treasurer of the Montana S. & R. Co., is negotiating for the Headwater G. M. Co. properties in Humbug district, near Yreka. Johnston has put men to work on the property.

The Medina G. M. Co. has bought the Johnson mine of Quartz valley, near Etna. This mine has been idle for several years. It was owned by the Johnson estate. The Medina Co. is operating in Oro Fino district in the Gardner mine and is made up of Eastern men.

Sonoma County.

Gold is reported found near Santa Rosa, in the vicinity of which there are mineral veins, some of which contain cinnabar.

Trinity County.

The dredger on the Junkans Ranch placers, near Weaverville, has ceased operations temporarily. The ground will be tested with a prospecting drill to ascertain the best place for working.

The Dorleska mine on Union creek, tributary of Coffee creek, near Trinity Center, is temporarily closed down, owing to heavy snowfall.

Tuolumne County.

(Special Correspondence).—The Soulsby mine, at Soulsbyville, is reported sold to Eastern men. W. Sharwood, one of the former owners, is still superintendent. The mine has a narrow vein in the granite, and is credited with a total production, to date, of over $6,000,000 in gold. It is developed to depth of 800 feet. A characteristic geological feature of the mine is the occurrence of pegmatite dikes, cutting the vein at various angles, and the presence of ore shoots adjacent to these dikes.

Soulsbyville, March 2.

(Special Correspondence).—The Black M. Co. has been incorporated under Wyoming laws by G. W. Campbell, W. G. Scott and C. S. Dow, and they have leased the Black Oak mine, near Soulsbyville, from the owners. The mine has been closed down for four months owing to a strike. In the meantime general repairs have been made throughout the mine and top works and the hoist has been raised and reset. Preparations are being made to resume full operations. Improvements will be made in the process of handling their ores. Experiments with the cyanide process have been made. The concentrates from the vanners will be reground and slimed in a ball mill and cyanided. The high-grade, sulphide ore will be sorted at the shaft as heretofore, but, instead of being shipped to a smelter, will be treated separately in one 5-stamp battery of the 40-stamp mill, concentrated, reground and cyanided separately. W. G. Scott is superintendent.

Soulsbyville, March 2.

At the Bell mine, near Tuttletown, the grading for the 20-stamp mill is finished and the masonry work started. In the mine sinking is still in progress. The shaft, which is down 610 feet, will be sunk 20 feet deeper. When this is done a station will be cut at the 600-foot level and drifts run east and west.

The Girard G. M. Co. has been incorporated — principal place of business Jamestown—by J. C. Davis, A. B. Overholser, C. M. C. Peters, F. P. Finkbohner of Jamestown and A. Arnold of Oakdale. ——The Golden West M. Co. has been incorporated—principal place of business San Francisco—to operate in Tuolumne county by P. Mariscano, S. S. Petrovich, C. Bovone, E. R. Hedges and G. F. Buck.

F. E. L. Robinson, of Sonora, has a bond on the Wheal Porrin mine, at Soulsbyville.——An oil plant will be installed at the Mack mine, near Groveland, and oil used as fuel.——The Clio mine, at Jacksonville, is being unwatered, and will be inspected by the Providence mine owners.

The Stockton Gravel M. Co., whose placer properties are in the Star district, near Columbia, is making an extensive prospecting season this winter. Their first shaft, down 80 feet, is in channel gravel.

C. A. Fitzgerald has bought the Homestead and Carolina placer mines, near Jacksonville.——L. Bosovich has bought a half interest in the Hard Scrabble placer mine (the Bosovich & Conlin), 1 mile east of Columbia.——J. H. Merrell has bought the Cosmopolite mill site near Groveland.

J. M. Merrell of Oakland has deeded to the Cosmopolite M. Co. the Cosmopolite quartz mine, near Groveland; also the Cosmopolite quartz mines Nos. 2, 3 and 4 and a millsite.

At the John Royal mine, near Columbia, the 10-stamp mill is running.

An air compressor and four machine drills for the Horseshoe Bend mine on the Stanislaus river, near Columbia, are on the ground. It is proposed to build a stamp mill. E. Goss of Sonora is superintendent.

The twenty stamps recently added to the Jumper mill at Stent were put in operation last week, and eighty stamps are now dropping.

It is expected the Clio mine at Jacksonville will be reopened for development work.

The Dresden G. M. Co. has taken over land traversed by and within 50 feet of New York gulch, near Jamestown, together with certain tunnels and other rights necessary to work the North Star, New York, Morning Star, Comet, Last Chance and Blue Gravel placer claims.

COLORADO.

Boulder County.

The Chlorination mill at Eldora is expected to be reopened under a bond and lease by C. G. Maynard, et al. of Cripple Creek. They have also a bond and a lease of the Enterprise mine on Spencer mountain and will start work at both mine and mill. Alterations and repairs are to be made at the mill which will greatly increase its efficiency.

The Arapahoe M. Co. is driving the crosscut from the 1000-foot tunnel towards the Cashier and Maud S. vein, near Boulder. Machine drills will be put in and work increased.——Roberts & Rodgers of Cripple Creek have a bond and lease on the Don D. group on Cedar mountain. They are sinking a new shaft and expect to go 200 feet before starting lateral work. The vein is 3 feet wide.

The Sunset G. M. & M. Co., at Sunset, reports work progressing, and 20 men are at work, besides ore teams, coal haulers and mill men. The company has bonds on the Skandia group and the Governor Routt group, and has also bought additional claims. It bought the 5-stamp mill (the Thompson mill), and is running it on Skandia ore. As soon as the machinery is placed the Governor Routt mine will be worked. There is a body of mill ore exposed, besides a streak of smelting ore.

Clear Creek County.

(Special Correspondence). — The lower tunnel of the Capital M. & T. Co. is in 1400 feet and cuts the mountain at depth of 700 feet. They expect to drive 200 feet farther before striking the vein they have on the surface. They are working one shift per day with machine drill. The upper tunnel is in 250 feet, driving by hand, and expect to drive it 130 feet farther. W. Cooper is manager.

D. Kennedy, manager of the Centennial G. M. Co., is drifting on the vein at the 600 foot level and taking out ore that averages $50 per ton. In places it is 5 feet wide. At present he is not running the mill, due to scarcity of water. He

has some smelting ore which runs high in gold and is shipped to the smelters.

The Transcontinental T. & M. Co. is preparing to put up a plant of machinery —compressor, etc.

Georgetown, Colo., Feb. 28.

(Special Correspondence). — The Jackson concentrating mill is handling the usual tonnage.——The Wnlthem M. & M. Co. is building a mill on Chicago creek. The initial capacity will he twonty-five tons, which will he increasod to seventy-five tons. This company has a lease and bond on the Ward & Ward Extension proporty and is sinking a shaft. Thoy will put in a completo hoisting plant.

Four new mills are in course of erection in Idaho Springs section of Clear Creek county. Nearly all the mills are running steadily and getting all the ore thoy cnn handle. Water has been scarce for some time on account of littlo snow.

Idaho Springs, Feb. 29.

(Special Correspondence).—The Empire Tunnol Co. of Georgetown is oporating the Gold Dirt mine nnd intends opening up the lower levels. The shaft is 515 feot deep, hut has not been opened up bolow tho third level. The shaft connects with the Aorta tunnel. The company is shipping one carload per week.

Empire, Feb. 28.

The Brazil group at Freeland is reported sold to the Con. Brazil M. Co. for $200,000. The group consists of sixteen claims and a millsite, the latter and four of the claims being patented. The group is near the Freeland, Lamartine, Gum Tree and Jo Reynolds mines. W. A. Haggott is president of the new company, and F. G. Shaffer of Idaho Springs secretary and treasurer, with G. Riley of Idaho Springs managing director. The millsite covers rights on Trail creek, and in addition to the mines the property contains thirty acres of timber. The property has been worked periodically and has produced $12,000, principally in high-grade matorial. Shaft No. 1 is on the west end of the ore body and has from 6 to 18 inchos of quartz, which milled $50 a ton. No. 2 has quartz which averages $30. The ore is sulphide of lead, carrying gray copper and nativo silver. The Big Forty, Tolland County and Bullion tunnols are surveyed to intersect the group under the present workings. The Burns-Moore tunnel will cut within 1200 feet of the group, and the Monarch tunnel, which will probably he the first available, will cut within 2000 foet of the group and at depth of 2300 feet from the surface.

Arrangements are made for starting operations on the Ramsdale and other lodes, near Georgetown, hy a local company.

C. I. Burt, operating the Vulcan mine above Silver Plume, has mado arrangements whoreby the sampler will treat a large tonnage of his ore. A number of men are employed in the various workings of the property, in addition to the regular leasers. High-grade ore opened last month is awaiting shipment. Assay values run 600 ounces in silver per ton. There is said to he no zinc in tbe ore. It is intonded to start machine drills next week, providing he can secure sufficient water for power. A drift is to run from the Pay Rock to cut under the Vulcan at additional depth of 200 feet.

Cadmium ore has been found in the Kitty Owsley mine's vein, near Georgetown, and shipments sent to Swansea, Wales, are reported to have given returns of $100 per ton after paying transportation charges.

Development is heing increased hy the Manhattan Union M. Co. at Argontino. Last week contract was awarded for sinking the shaft 400 feet from the surface and another contract given for drifting 500 feet from the 400-foot station. There is a tunnel driven 800 feet. The mine is equipped with machinery. At the 400-foot station of tho tunnel level a raise has heen started which is up 120 feet, says Superintendent Tingle.

The operators of the Magnet mine, near Georgetown, have started shipments of high-grade ore. A winze is heing sunk and a drift will he run for cutting under the ore hodies.

Superintendent C. L. Tingle of the Stevens mines and mill at Argentine, says preparations are being made to increase the mill to 100 tons daily capacity. The present output is 30 tons daily.

Chaffee County.

The Jasper mine, in Turret district, has heen sold to the Four B's M. Co., of Lincoln, Neh., for $25,000. The property has heen operated under hond and lease hy the Four B's Co. It is 1 mile northeast of Turret and 12 miles north of Salida, and is equipped with machinery. At present there are several carloads of ore in the drifts ready for shipment. The shaft has heen sunk to 325 feet on the main vein. At intervals the vein is tapped hy crosscuts from the shaft. The values are principally in gold, hut some copper is shown. The new owners will add more machinery and improve the present plant, with view to handliug larger output.

Fremont County.

The Union mill at Floreuce of the United States R. & R. Co. fired up another roaster last week, and it is expected by March 15th the entiro mill will be running full hlast. It has been operating at about one-half capacity since January 1st on account of not receiving enough ore from Cripplo Creek. The ore from the Golden Cyclo mine hns hoon diverted from the Standard mill in Colorado City to Florence. When the plant is in full blast fifty more men will he required.

Gilpin County.

(Special Correspondence).—Scarcity of snow in this section is causing anxiety as to supply of water for the coming summer. Tho water in the creeks is the lowest for several years and but little snow in the hills. Work is progressing as usual in the Central City minos, and nearly all the mills are husy.

V. M. Came and B. G. Granville, owners of the "Gilpin County Now Treatment" of low-grade gold ores, are preparing to work on a largor scalo. They now have a lahoratory where they are experimenting, hut will huild a plant to handle 125 tons of ore per day. They will treat ore running from $5 to $15 per ton.

Central City, Feh. 29.

(Special Correspondence).—The Fish-Cook-Greggory and Bobtail mines, which have heen closed for soveral months on account of litigation, will start up March 1st. O. B. Thompson, manager for these properties, has sunk the Cook shaft 500 feet deeper, making it 1400 feet. The mine has a three compartment shaft. Thompson will also start the mill which has also heen idle since tho mines wore closed down.

Black Hawk, Feb. 28.

Near Rollinsville the Bluegrass M. Co. of Phœnix has completed its 10-stamp mill and will hegin crushing ore this week. They have several months run on the dump. K. C. Parrish is in charge. ——The Shepherd tunnel, which formerly produced ore, is heing retimhered and the company expects to increase development.

The Phœnix-Burroughs mine on Quartz hill, near Central City, has put in a new 1-inch steel cahle 3000 feet in length for hoisting. During the month of January the consolidated properties of this company shipped 147 cars (1250 tons) to the stamp mills, concentrator and sampling works. From sixty to seventy-five men are employed on company and leasing account, says Manager R. Sykes of Denver.

The Quartz Hill M. Co. is operating the Golden Dollar mine, near Russell Gulch, with W. Bradden in charge. Machinery has heen put in and a shaft huilding erected. Sinking is in progress. They will crosscut to the vein.

The Roderick Dhu M. Co., operating the Protection mine on Quartz hill, near Central City, is shipping twenty tons of ore per day to the mills on North Cloar creek. The manager reports that the ground is showing increased values and that they have run the grade up to $6.50 per ton.

Missouri parties are interested in the Russell group at Russell Gulch, and developments continue regularly under Superintendent A. Thompson. A 60 H. P. hoiler has heen added and sinking is under way. The shaft is down 400 feet. Steam drills are used. Both sinking and station pumps are handling the water. The company has an agreement with the Old Town mine, wherehy they are permitted to drift west from the 200-foot level of that property to explore ground on the eastern end of the Russell group.

Gunnison County.

Dice Bros., owners of the Lottie K. mine, near Pitkin, are shipping ore. Six inches of $40 ore is reported in a winze sunk near the hreast of a 130-foot tunnel. The values are gold and lead.——The Corona M. Co. of Boston, Mass., has started work on its Oh My mine in Bowerman. A tunnel will be driven on the vein, and development will he under supervision of W. J. Nourse.——Some payahle copper ore is reported showing in a 40-foot shaft on the Copper Field lode. A tunnel is in 35 feet, which will cut the vein showing in the shaft at depth.

Lake County.

(Special Correspondence).—W. S. Jones, superintendent of the Cloud City mine, has the shaft down 504 feet, and will sink 200 feet farther. This property adjoins the Midas-Coronado and other producers in the "down town" district.

Leadville, Feh. 28.

Pueblo County.

A ship load of South American silver and gold ore arrived last week at the Eiler smelter of the American S. & R. Co. of Puehlo via the Colorado & Southern road from Galveston, Texns. Other shipments are said to be coming in from Chili and Peru, and it is largely on necount of these foreign shipments that the company's Philadelphia smelter will be started up at full capacity. At present there are five furnaces and fourteen roastors at the Philadelphia plant not in operation. As soon as these are started up the numhor of men will he increased about 1000, making tho total number of smelter men employed in Pueblo 2500.

San Juan County.

Sisson & Graham have started up work again on tho Bolla tunnel (the old Northern Light). A company has been organized, and will increase development until all the veins in its course are oponed up. Further up, near timberline, the tunnel will reach the Elvira-Virginia vein, which has a vein showing on the surface silver and lead, with milling valuo in gold. The Northern Light M. & M. Co. owns thirty-six claims on line of its tunnel site, east of Cemont creek, near Silverton, and has a bond on twonty-seven (oprated by Graham) on the Red mountain side. The coming summor power drills and improvements will go in.

The Yukon tunnel, near Silverton, is going ahead and has attained a distance of 1950 feet. Two veins have heen cut, one showing copper and iron sulphide, says Manager Lamont. He is arranging with the San Juan S. & R. Co. to ship this ore to the smelter.

The Henrietta mine has started up. The drifts on No. 6 level north and south on the Henrietta vein will ho driven and the stoping of ores in other levels will be started this month, tho tram line heing in readiness to transport tho copper ores to the smelting plant.

The Gold King M. Co., near Silverton, hesides the amalgam scraped off the plates every twenty-four hours, is getting out five carloads of concentrates daily, says the Silverton Standard. Each car has a capacity of twenty tons.

San Miguel County.

The Black Bear M. Co., in Ingram basin, near Telluride, reports drifting progressing on south vein of crosscut, and a point 355 feet from intersection has heen reached. A shaft is heing sunk from this drift 75 feet from intersection with the crosscut and 40 feet deep, showing a 5-foot vein of ore. It is intended to put in an electric hoist as soon as the shaft reaches depth of 100 feet; in the spring ore will he sent to the Smuggler-Union mill.

The Butterfly-Terrihle plant at Ophir, with forty men at work, has heen producing 175 tons of ore daily. The ore averages $9 per ton, the values heing saved on plates hy amalgamation. The east drift of the Butterfly, which is cut by the crosscut tunnel, has heen driven 600 feet. There remains 200 feet before the eastorn limit of the Butterfly territory is reached. The distance hetween this drift and the next level ahove is 320 feet. The pay streak from which the ore is heing extracted is from 1 to 3 feet in width.—— V. U. Rodgers and F. Fox, doing development work on the San Bernardino, opposite the Butterfly, expect to complete the blocking out of ore by April 1. Development work on this ore hody has heen going on for several months. The San Bernardino ore runs high in silver values and 30% in lead. This ore is shipped to the smelter.

The Rio Grande Southern M. & M. Co. for the past eight months has heen operating the Shoemaker group of mines 2 miles north of Ophir. An extension has been secured on the company's lease and option on this ground, and this spring the company will increase development work. This work contemplates the driving of a crosscut tunnel to cut the vein at a vertical depth of 1000 feet helow the surface. P. B. McAtee of Durango and G. Sanders of Telluride are directors of the Rio Grande Southern M. & M. Co.

The Gold King mine in Turkey Creek hasin, near Telluride, will have development work increased hy the company and the mine put on a producing hasis. The Gold King is heing operated hy M. Bertolin, who holds a lease on the property. There are ten levels in the Gold King mine.

Summit County.

J. C. Whisler, superintendent of the French Gulch G. M. Co. (formerly the Mecca Placer M. Co.), near Breckenridge, says a pit, 75x150 feet, was excavated to hedrock (from 13 to 19 feet deep) with hydraulic elevators and a boulder hoisting cahleway put up. A douhle or branching Y-shaped sluice was laid along the hedrock and the gravel washed with giants into the upper hranches of the Y. After leaving most of the placer gold in the hranch sluices — which were so arranged that they could be cleaned up independently, so that while one continued to work the other could he relieved of the accumulated gold—the tailings passed to the main sluice and through it to the hydraulic elevator pipes. As the season advanced and the water supply became insufficient to both handlo the tailings through the elevator and to keep the pit drained, the steam pump was used to remove excess of water from the pit. When cold weather set in Superintendent Whisler rigged up a washing plant in a shed made by hoarding up part of the trestle which supports a portion of the elevated flume. Ordinary sluice hoxes, lined with rifles, nre arranged next tho wall; the steeply sloping boxes discharge from one into the other until the gravel has passod ovor about 40 feet of riffles altogether. The building is warmed hy a large wood stove; the water used, warmed by waste steam, is pumped into the upper sluice hox from the pit (to which it returns and is usod over again) hy the steam pump. The hedrock drifts are driven 5½ feet wide and 6½ feot high. The richest gravel is wheelbarrowed to the washing room and is shovoled into the upper hox; the second grado gravel is wheeled to the head of the Y sluice, where iu the spring the giants will disintegrate the mass and force it through the sluices. Three men are employed at present at an expense of $12 per day. Whisler says the output averages $24 worth of gold and nuggets per working day.

The Excelsior property, consisting of lodes and placers, at mouth of French gulch, near Breckenridge, will he reopened the coming season, says Manager Braun. The principal owner of the Excelsior is W. Sieck of Chicago, Ill.

Teller County.

C. M. Crowder & Co. will sink a shaft on Colorado Boss No. 1 on Bull hill, Cripple Creek, owned hy the Cripple Creek Con. Co. The shaft is down 150 feet and it is intontion of lessees to sink 600 feet farther. On every 100-foot level lateral work will he done. The lessees have opened a body of ore. They have also taken a lease on the lower working of the Anaconda mine, which adjoins their claim, and are sinking a winze on the level 400 feet helow the tunnel level on a hody of ore of shipping grade. The same lessees have a lease on the south end of the Iron Master claim of the Doctor-Jack Pot Co. It is expected they will start sinking a shaft there from surface, and if ore is opened up in any of the three properties all will probahly he worked from their main shaft.

Drainage of the Cripple Creek mines is heing steadily accomplished hy the El Paso tunnel, says the Gazette. The decrease reported in the Elkton and Mary McKinney properties approximates 3 feet a week, while proportionate gains are estimated hy other companies where regular measurements are taken. The eighth level of the Elkton and the sixth of the Mary McKinney are not far helow water line, while in several other mines admission has already heen gained to the submerged levels. According to measurements made at the portal last week hy Engineor Jacquith, 6500 gallons a minute are coming out, and that has heen steadily maintained for several weeks. In the meantime the east heading is advancing into Raven hill and recently cut several small feeders. The hreast of the tunnel is over 6000 feet from the portal. It is reported the owners and general managers of the Bull Hill mines, especially those affected hy water, propose further extensions of El Paso drainage tunnel. It would he necessary, perhaps, to vary the course slightly and to drive it another mile to accomplish good to the mines on Bull hill and tho south slope of Battlo mountain. Should this tunnel he continued into Bull hill it would drain such mines as the Findley, Golden Cycle, Hull City Placer, Last Dollar and others to a depth of 1300 feet. This would enahle these producers to use pumps, if the water quostion trouhled them helow this depth. It is thought it would require nearly two years to do this work.

Manager Gilhert of the Peggy G. M. Co., at Cripple Creek, expects this week to start sinking the shaft on the Le Clair claim another lift or to 400 feet from surface and from that point extensive lateral work will he done. The ore shoot west of the shaft is said to he flat, while that to the south is nearly vertical. During January 150 tons of ore returning values of five ounces gold per ton were sent out. Besides this, development work was done.

Lessees Harrison & Seaver, operating the W. P. H. mine, in which they made the high-grade ore strike last month, have extended the hroast of the drift 20 feet in a southerly direction, and have opened up a 4-foot vein from which assays give returns of $500 per ton. The winze on the rich streak has heen sunk to depth of 12 feet from the hottom of the shaft, and the 16-inch shoot is reported to maintain its high average. The lessees are also continuing sinking of the shaft, having reached a depth of 40 feet helow the 245-foot level. They will put in a two-

drill air compressor, also a hoist. When these additions are made the shipments of second and third-grade ore will be increased. T. Walsh, who has a lease on the Forest Queen, which adjoins the W. P. H., and which is thought to carry the extension of the W. P. H. shoot, is sinking the shaft. On reaching the 200-foot point lateral work will be started. Lessee Walsh has done considerable lateral work at depth of 185 feet from the surface.

The output of Cripple Creek district for February amounted to $1,769,600, a decrease from January of $83,400, which is explained by February being two days shorter than January. The tonnage for the month is 54,500, with an average value of $29. The month of March is expected to show increased value over February. There is more ore being sacked by mines at the present time than ever before in history of Cripple Creek camp. The following table shows individual treatment during February:

	Tons.	Total.
U. S. R. & R.	25,000	$625,000
Portland	8,300	249,000
Telluride	4,000	160,000
Economic	2,800	61,600
Dorcas	2,700	121,500
Homestake	1,700	8,500
Sioux Falls	1,000	4,000
Smelters	9,000	540,000
Totals	54,500	$1,769,600

The Zenobia G. M. Co., controlled by the Stratton estate, has leased the Zenobia claim on Bull hill, Cripple Creek, to J. M. Wright for eighteen months and 27½% flat royalty. The executors of the Stratton estate report that they will not consider any applications for leases on the Bull hill property of the Stratton-Cripple Creek Co. The property of this company on Bull hill will not be leased for some time yet.

Lessees Francis & Co., operating a lease on the Proper claim of the Stratton estate, up Poverty gulch, near Cripple Creek, are putting in a plant of machinery. A boiler with 80 H. P. capacity and a compressor will be put in. The lessees have sunk the shaft to a depth of 120 feet with a whim. They intend to sink the shaft to a depth of 300 feet before doing lateral work. They have opened up a vein.

IDAHO.

Boise County.

The Osborn mine at Horseshoe Bend is being equipped with a steam hoist, pump and other machinery by Superintendent G. Leighton of the Idaho G. M. D. Co., which owns the mine. About 7000 feet of underground work has been done. Manager J. A. Richardson says a mill will be built with a capacity of 100 tons per day.

Custer County.

C. E. Gable, manager of the Golden Sunbeam M. Co.'s mines and mill on Jordan creek, near Custer, says the company will increase the capacity of the plant to 300 tons daily. At present the management is reducing thirty tons daily. The Sunbeam group covers a porphyry sheet, says Manager Gable, in which are contained gold values of $4 per ton, the proposition a free milling one, while the expense of mining is confined to quarrying.

Elmore County.

Oil is reported struck at Medbury Hill, between Mountain Home and Glenn's Ferry.

Superintendent B. Ford of the South Boise M. & D. Co., which owns 320 acres of bar placers and 320 acres of dredging ground at the junction of the South Boise and Big Smoky rivers, near Pine Grove, east of Boise, says he is preparing to resume. A hydraulic plant with a capacity of 2000 yards per day was put in last fall, which will be put in operation as soon as the weather will permit. He says the gravel on the bar is from 100 to 120 feet deep and will average 40 cents per yard. In addition to this, the company owns other property near by, which it is intended to develop the coming summer. Ford also has charge of a group owned by Roanoke, Va., men, consisting of 520 acres, 12 miles from the South Boise M. & D. Co.'s holdings. It is intended to put in two hydraulic plants the coming summer.

Idaho County.

Dobbin & Chambard are down 42 feet in the shaft on the Lost Lake property, near Hump, says the Spokesman-Review, and have crosscut 12 feet with 4½ feet of ore showing free gold. Sinking was stopped on account of water.——The Atlas has run into some of the best ore taken out of the vein.——Work on the Granite has been completed for the winter. Fifty feet of shaft has been sunk and 16 feet of crosscutting done. Some good ore has been taken out, but the ledge is still broken up. Drifting will be commenced in the spring at a depth of 250 feet.——At the Jumbo the new 10 stamps are dropping.——Del Rio tunnel is in 315 feet, and some large kidneys of ore are being found, showing free gold. Crosscuttng will be commenced.——The Crackerjack Co. will begin in a few days on the crosscut tunnel from the feeder to the main ledge, 70 feet ahead. Machines will be put on this work and drifting north and south will be commenced as soon as the ledge is cut. The mill will be started about March 15.

J. J. Bye of Pittsburg, Pa., part owner of the Pactolian M. Co. mines in Rapid River district, states that at the Pactolian a winter force of six men is at work and developments are progressing. Fair-grade ore has been opened up. The company will increase operations and also will build a plant during the coming season.

Kootenai County.

The J. Ferguson claims at Blacktail have been sold to the Wisconsin M. Co. for $50,000. Further development work will be started next month. J. Ferguson of Sandpoint is superintendent.

R. E. Stratton, superintendent of the Panhandle S. Co., at Sandpoint, says men will be put to work next week and the smelter will be put in operation.

W. T. Bailey of Duluth, Minn., part owner in the Continental mine, near Porthill, says development work in the mine will be increased this season. A compressor is being set up. They are now working 100 men, and fifty of them are in the mine. Shipments are being made to amount of forty tons a day. They haul the ore 22 miles to the railroad. Since the sledding has been good not a day has passed without this amount going to Porthill.

Shoshone County.

Under management of O. Linn, the Nine-Mile M. Co. resumed operations this week, after six months' idleness. The mines are on Nine-mile creek, 3 miles above Wallace, and 2200 feet of tunnel work has been done. In the lower tunnel a crosscut will be run to tap the ledge at depth of 500 feet. In the upper workings there is said to be a body of silver-lead ore. There are six claims in the group, all patented. O. Linn and J. Flinck are principal owners.

KANSAS.

Cherokee County.

Ford & Troupe of the Mission mine, south of Baxter Springs, are preparing to put in a 150-ton crusher plant at their mine.

At Galena, coal supply is on the ground for the Lou Dillon M. Co., and operations will start this week. The Lou Dillon was formerly the Cousin ground, and will be operated by Stone, Pinson & Hallam of the B. & E. M. Co. They have a shaft down 120 feet and have opened up a good face of jack. The Cousins mill will be operated by a Webb City company.

MICHIGAN.

Houghton County.

Operations the coming summer will explore the deposits of the South Range, to determine their extent outside of the Baltic, Trimountain and Champion lines. The exploration of the Globe property will start as soon as the weather conditions permit, says the News. The Globe tract is owned by J. Stanton, of New York, and consists of 3200 acres south of the Champion mine at Painesdale.

The Calumet & Hecla No. 20 shaft on the Kearsarge lode, near Calumet, has struck the lode and found it well mineralized.

The strike of the miners at the mines of the Copper Range Con. C. Co., at and near Painesdale, continues.

Keweenaw County.

The Ahmeek management reports it is intended to supply one head at the Tamarack mill with rock from the Ahmeek mine, near Allouez. The union with the Seneca is being negotiated.

The Mohawk mill, near Allouez, started three heads in operation this week.

Ontonagon County.

At the Adventure mine at Greenland the daily rock output is 500 tons, and is all being taken from ground tributary to No. 3 shaft. The aim of the company at present is to sink this shaft as rapidly as possible to a depth of 1000 feet to ascertain the value of the lodes at that point, and no special effort is being made to secure an increase in the daily output of rock.

It is reported the Belt mine will be reopened in the spring by New York parties. The Belt is east of the Hilton end of the Adventure Con., near Greenland, and is owned by J. H. Rice et al. of Houghton.

MISSOURI.

Jasper County.

The Joplin News-Herald says the highest price reported paid for zinc ores last week was $38 per ton, and the assay price $35 per ton of 60% zinc. Lead advanced to $56. The shipment is 700 tons of zinc less than the preceding week, partly attributable to a lack of cars for loading the ore bought. The value was $25,000 less for the entire district, but the value of the ore sold within 3½ miles of Joplin was $83,815, or nearly as large as the preceding week.

The No Name M. Co. has been organized in Carthage to operate on a sub-lease of four acres on the strike made by J. W. Aylor and A. R. Bowen on the Williams land, west of Carthage. Mineral was found at 55 feet depth and was continuous from that to a depth of 120 feet, except one break of 15 feet between two runs of ore. Sinking of the shaft on the drill hole was begun last week. The incorporators are V. Grieb, D. & D. S. Miller, L. L. Ashcraft, A. Myers, R. A. Goldsbury and D. McCoy.

A company has been formed to prospect a tract of land, 4 miles south of Carl Junction, by E. S. Keskeys and S. D. Chitwood & Sons. They are prospecting the tract with a drill and have struck shines.——The Power M. Co. of Joplin has been incorporated by W. P. Leon, C. W. Power and W. J. Montfort.

MONTANA.

Jefferson County.

P. Gruner and J. Wassen are working the Mantle mine in Cataract district, 2 miles from Basin, on lease and bond. It is worked by a shaft down 50 feet and 70 feet of stopes and drifts. They are averaging a car of ore a week, which is being shipped to Butte for treatment. The ore is lead carbonate carrying values in gold and silver. The vein is 2 feet wide.

The Elkhorn M. Co. has given a bond and lease on the Elkhorn Queen mine for $20,000 and a royalty of 10% to R. C. Wallace, J. H. Freezer, Z. T. Vinson and F. S. P. Lindsey of Helena. The mine is near the Elkhorn and is a gold, silver and lead proposition.

Lewis and Clarke County.

J. C. Cory of Helena has a bond on the Atlanta group, in Rimini district, near Helena. There are three claims, the Gum Boot Jim, Atlanta and Hunter—a mile from Rimini. There is a shaft down 180 feet and crosscut tunnel to tap bottom of shaft, which latter is nearly finished. The ore at the bottom of the shaft is said to be in shipping quantities. All this work is on the Atlanta. Work will be started to develop the entire group.

Powell County.

The mining property at Danielsville of F. A. Heinze, of Butte, is reported closed down, throwing sixty men out of employment.

NEVADA.

Eureka County.

P. Porter, manager of the Keystone M. Co. at Eureka, reports the lower tunnel, driven into the mountain 160 feet below the next one above, has struck the ore, showing vein of 12 feet width.

Lincoln County.

Gold bullion of $31,000 value, the result of the cleanup at the mill for last half of month of January, was shipped last week from Bamberger's De Lamar mines, at De Lamar.

J. Knight of Provo, Utah, has bought a half interest in a group of claims in Silver Park mining district, 35 miles north of Pioche, and the Nevada-Park M. Co. has been incorporated, with J. Knight, L. Holbrook, R. E. Allen, S. A. King and J. J. Knight as officers. The holdings cover ten full lode claims, three of which are patented. For fifteen years the mine has been idle.

The first payment has been made on the Welland & Clifford group of mines at West Point, near Pioche, by C. R. Rives of the Pioche Nevada Con. M. Co. The Pioche Nevada Con. M. Co. has the two Clark claims near West Point, namely, the Comstock No. 1 and Comstock No. 2.

J. N. Williams and J. M. Yates of Boulder, Colo., have a twelve-month's working bond on the Blackhawk group of mines, near Searchlight, for $30,000. Men have been put to work. The Blackhawk group consists of three claims and is east of the Pompeii mine. On the surface the vein averages 4 feet. —— Contractors are sinking the Pompeii shaft at the rate of 60 feet a month. The contract calls for a total depth of 300 feet, besides crosscutting and drifting. They are down 200 feet, says Manager Spare.

A strike has been made at Camp Duncan, 12 miles northeast of Searchlight and 4 west of the Colorado river. Duncan & Sinclair of Tonopah, W. Thurman, H. A. Perkins, E. K. Wood, G. H. Hamstadt, G. Dupont, W. L. Colton and L. Wheatley of Searchlight are doing development work. The ledge on Mount Duncan crops 12 feet in width. A tunnel has tapped it at depth of 100 feet.——The Woods group at Camp Duncan has been sold to W. H. Fuller. The group comprises the Roosevelt, Ivanhoe and Golden Terra, on which little development work has as yet been done.

Lyon County.

J. H. Rae, manager of the Como-Eureka mine, owned by the Federal Co., Ltd., at Como, near Dayton, says five more stamps are being added to the company's mill, which is to be further equipped with a cyanide plant. A new development of 6 feet of free-milling ore, showing average value of $12 gold per ton, has been made in the mine. The mill is running to clear away an accumulation of low-grade ore, and when the crushing capacity is increased it will be started on the high-grade ore body. A pumping plant, with a water-lifting capacity of 100 gallons per minute, is on the ground and will be set up. It will be operated by electric power transmitted from the Federal Co.'s dynamo plant on the Carson river at Dayton, which can supply 250 H. P., only 50 H. P. of which is required until the pumping plant is set up, and the capacity of the mill enlarged to handle 100 tons of ore daily. The milling plant is also equipped with rollers, which pulverize the ore after it has passed through the coarse screens of the stamp batteries, and from these the pulp passes over six concentrating tables.

Washoe County.

J. H. Sheehan has resumed operations on the Crown Point mine at Olinghouse.

In southern part of district eighteen men are at work developing and prospecting their claims at Ninth Crossing, near Wadsworth. The Ninth Crossing G. M. Co. of Reno has miners sinking a shaft 4x6 feet, which is down 50 feet. Superintendent T. Hart reports a crosscut will be started east to cut a ledge of quartz of known values at surface. Ore is free milling.——M. Lund, R. Nelson and R. Peterson of Reno have a group of five claims with ledges of free-milling gold ore. The ledge which is being developed is reported 5 feet in width. A crosscut is being run to tap a ledge at a depth of 120 feet—now in 20 feet. Further up the hillside is a cross vein of 18 inches wide carrying $10 in gold.

NEW MEXICO.

Grant County.

The St. Louis-Gold Gulch M. Co. will put in a steam hoist on the Lucky Bill mine at Gold Gulch, also on the Flying Dutchman, together with machine drills and a 500-foot capacity sinking plant. They will remodel the Gold Gulch concentrator as a 50-ton cyanide plant.

Rio Arriba County.

A strike of coal is reported made in Gallinas district, west of Ojo Caliente, and is 2 miles from the survey of the proposed railway line from San Felipe to Durango. It is 40 miles southwest of Tres Piedras. The Denver & Rio Grande Railroad Co. has men making examination of the deposits. It is claimed the line of railway will tap the deposits of mica in Alamos canyon, west of Petaca, and enable those properties to be worked, most of them being idle at present on account of the long haul by wagon to the railroad. The Superior Mica Co. of Milton, Pa., is doing work on 125 acres of ground there and is preparing to begin shipping of mica this month.

Sierra County.

The Hillsboro G. M. Co., which owns the Ready Pay group of mines at Hillsboro, largely owned by A. G. Brown of Utica, N. Y., is arranging to increase development work. The company has a 3-stamp mill. Owing to lack of water which is being arranged for, the mill cannot be started as yet. —— E. F. Pearson, manager of the Richmond G. M. Co., is arranging to increase development work on that group of mines. Work on the lower tunnel has opened up additional bodies of milling ore.

Socorro County.

A gold field is reported located in the San Mateo mountains, 30 miles west of San Marcial, and near Rosedale, by E. L. Watkins.

The Dividend M. Co. has thirty men at work on its property at Estey City. The company is preparing to put up a 50-ton smelter.

OREGON.

Grant County.

The Oregon Gold Dredging Co. has been incorporated to build a dredger on the Crane Flat placers, near Granite, work on which will be started this month. G. J. Barrett of Granite is local manager.

Josephine County.

J. M. Depew reports having struck the Boulder ledge (or "Old Spot," from the spotted appearance of the ore), with O. P. Templeton and A. G. Arnold. Shafts have been sunk, open cuts made and tunneling done. The ledge is on the east side of Mount Baldy, 4 miles from Grants Pass.

SOUTH DAKOTA.

Lawrence County.

Machinery is being put in by the Hidden Treasure G. M. Co. and sinking will be resumed, says Superintendent W. Lawlor. A gasoline boist and a separate gaso-

line engine for the electric lighting plant are being set up. The dynamo will operate the drills and lights. This shaft has been started from the floor of the main tunnel and is down 50 feet. The hoisting machinery is being set up at the station cut in the tunnel, which is 100 feet underground. In the spring a larger steam hoisting plant will be set up at the surface, to which a raise will be made from the present tunnel level.

The Wauconda M. Co. is preparing to put in machinery on its mine 5 miles south of Lead. Delay has been occasioned by the deep snow, says F. Ames, superintendent.

Ore has been opened on the 500-foot level by the Columbus Con. M. Co. in Sawpit gulch, near Central City. Two veins have been cut, one west and one east of the main shaft. They are equally distant from the shaft, being each 100 feet. At depth of 200 feet the principal ledge of the Columbus is said to be 247 feet wide and carries gold values running $3 a ton. This ledge is opened on the 200-foot level by crosscutting and drifting. The company has plans completed for building a mill of 1000 tons daily capacity in Sawpit gulch near the shaft. Water will be pumped from Deadwood gulch. Another shaft will be started at ¼ mile north of the main shaft.

Pennington County.

The Mainstay M. Co. is preparing to resume work at its mine and mill near Keystone, arrangements having been made for handling its concentrates at a Denver, Colo., smelter, says Manager T. R. Griffith. The Bismarck ore, while carrying values in free gold, also contains a large percentage of values in concentrates. Concentrating machinery is being put in.——J. Madill began work on the Eleventh Hour mine last week, taking out ore for shipment. Three cars of twenty tons each have been shipped to the Imperial mill at Deadwood, and regular shipments are to continue. The ore is hauled from the mine by sleds 1¼ mile down grade to Iron Creek station.

UTAH.

Iron County.

With heavier pumps put in, drifting on the 300-foot level of the Johnny mine, at Stateline, was resumed last week.

Juab County.

The Showers Con. at Diamond, in the south end of Tintic district, has been dismantled, the machinery removed and operations have been suspended indefinitely.

Copper ore has been opened up on the 1400-foot level of the Black Jack mine at Tintic, near Eureka, says J. Knight of Provo, manager.

Arrangements have been made whereby the Star Con. mine of Tintic, near Eureka, will be equipped with a chlorination plant. It will start in with capacity of 200 tons daily, which will before end of year be increased to 500 tons daily, says W. V. Landers of Boston, Mass., manager.

Morgan County.

Secretary N. B. Dresser of the Park City Co-operative M. & D. Co. of Park City, operating on the Copper mountains, on Weber river, reports ore had been struck in the face of the drift 25 feet from the mouth. It consists of a seam of the black oxide of copper on the foot wall. More men will be put on.

Salt Lake County.

A hoist has been put up at the Galena mine in Bingham, one of the United States M. Co.'s properties.

H. M. Crowther, manager of the Continental M. & S. Co. at Alta, says he is preparing to build a concentrator to have initial capacity of 100 tons daily.

Summit County.

After a month's partial suspension of operations for repairs and installation of a pump, the Silver King Con. mine of Park City has started up again.

Tooele County.

Work has been started at the Black Diamond mine at Stockton.

Wasatch County.

A contract has been signed by which the output of hydrocarbons from the mines of the Gilson Asphaltum Co. of Salt Lake City in the Uintah reservation section is to be afforded an all-rail outlet over the tracks of the Uintah Railway between the camps and Crevasse on the line of the Denver & Rio Grande. Grading will begin next week and the line is expected to be ready for operation by July 1. With this as an outlet, the asphalt company will the present year begin production, a number of contracts for the product guaranteeing it a steady market. The first connection will be made with the Dragon ledge. The next connection, as projected, will be with the interests of the Raven M. Co., in the southern part of the reservation. Sutherland, Van Cott & Allison of Salt Lake City are interested.

Weber County.

The Great Northern C. M. Co. has been incorporated at Ogden for developing the Great Northern group of claims, in the Sierra Madre mining district, by A. W. Agee, D. Convery and S. H. Browne.

WASHINGTON.

Franklin County.

R. W. Taylor and J. W. Kouba are preparing to put in machinery to work their placer ground on the Columbia river, 5 miles above Pasco. It will include a gasoline engine and a pump, with capacity of 600 gallons per minute, 20 foot elevation. The river is 200 feet distant, and water will be taken therefrom through a canvas hose and used in hydraulicking the banks through sluices into a gold-saving machine. They report having 4 feet of pay earth near surface, and another 14 feet deeper, 3 feet thick.

Snohomish County.

The Everett R. & Electric Co. has started construction of a power plant to generate 15,000 H. P. at Lake Isabel, on the Great Northern, 32 miles east of Everett. It is said the intake for the 32-inch pipe will be 30 feet below surface of Lake Isabel. The pipe will be 12,000 feet long, with a fall in that distance of 2,500 feet. Owing to the heavy pressure, a special steel pipe will be used, decreasing in diameter to 20 inches near the nozzle, which is to be five-eighths inch diameter. Using a Pelton wheel, this stream is intended to develop 10,000 H. P. Later another stream and wheel will be put in, developing 6700 H. P. The pressure on the steel pipe will be 1100 pounds to the square inch. The speed of the water, leaving the nozzle, will be 417 feet per second. It is said the only plant in the world to exceed this in its head of water is one in Switzerland, having a head of 3700 feet. In California there is one with a head of 1900 feet at Electra, Amador county.

It is reported the Sunset C. M. Co., operating at Index, will build a concentrator near the Index mine.

Stevens County.

The annual report of the Crystal Marble Co. of Spokane, operating in Stevens county, shows: Last year 300 tons of marble were quarried and this year 400 tons are channeled. This is of the diamond dark variety. Other kinds are in the company's holdings and will be quarried this season. The channeler was started last week on a crystal white ledge which has been uncovered, and is reported free from surface defects. The company is working twenty men at the quarry, and as soon as the snow is gone the force will be doubled. It is expected additional channelers, hoists and derricks will be put in, says F. A. Chase of Spokane, secretary and manager.

FOREIGN.

AFRICA.

Cape Colony.

Arrangements have been made with the Goldfields Diamond Drilling Co. to bore 2500 feet at the following mines: The Columbia, 500 feet from bottom of straight shaft; the Queen Cross, 1000 feet from bottom of straight shaft; and the East Queen Cross and Vesuvius, 1000 feet from surface. The Vesuvius is also going to prospect with the diamond drill. The ore put through the mills for the month is 22,241 tons 9 cwt., yielding 25,619 ozs. 2 dwts. 22 grs., being an increase of 2639 tons and 1201 ounces when compared with the corresponding month of the previous year. The value of mill gold for the month is £85,948 1s 3d. Old tailings treated by cyanide show 1850 tons for 624 ounces, being a decrease in tonnage of 3259, and in bullion 2086 ounces. Thirteen thousand eight hundred and seventy-one tons of new tailings were treated for 8601 ounces. The new tailings show a decrease of 6407 tons and 2658 ounces when compared with December of the previous year. Assayer's return is 203 tons for 481 ounces. The total value of the product from all sources is £101,768 1s 2d. The dividends for the month show an increase of £31,022 4s. For this month £77,522 4s was paid in dividends, and in December of the previous year £46,500. Of the dividend producing mines for the month, the Queen Cross shows the return of over three ounces to the ton, 2432 tons of quartz being treated at the mill for a return of 7830 ounces of gold, the value being £26,045. This mine has paid in dividends for the month £45,000, as against £30,000 paid in December of the previous year. The Brilliant Central comes next with £10,000 in dividends for the month, the yield from the mine being 3239 tons for 3705 ounces. There is a considerable improvement of late in the value of the ore produced from this mine.

Transvaal.

The Transvaal Chamber of Mines at Johannesburg reports the gold output for January amounted to 278,867 fine ounces for Witwatersrand, an increase of 157 ounces over December, 1903. The output for the outside districts was 9957 fine ounces, an increase of 2606 ounces.

AUSTRALIA.

Queensland.

The gold returns of Queensland for the month of January are:

	Tons Crushed.	Yield in Ounces.
Charters Towers	18,600	17,100
Croydon	4,100	2,300
Gympie	9,200	4,900
Mount Morgan	26,000	9,900
Ravenswood	2,500	2,700
Other fields	1,300	1,000
Alluvial		600
Total yield		38,500

Victoria.

The Victorian gold yield for month of January amounted to 53,109 ounces, being an increase of 10,921 ounces over January, 1903.

Western Australia.

It is reported opal has been found 3 miles from Coolgardie by J. T. Moore. The ground in the vicinity of the find has been pegged in all directions.

BRITISH COLUMBIA.

Boundary District.

Development work has been resumed on the Blue Jay mine, in Skylark camp, 2 miles below Phœnix.——Manager Rea, of the Betts and Hesperus, on Hardy mountain, is preparing to put in a 5-drill air compressor.——W. Newton, part owner of the McKinley claim, in Franklin camp, says development work will be resumed this spring. The McKinley has surface showing of values in copper and gold across a ledge that has been stripped for 25 feet.

East Kootenay District.

The oil industry and the development of oil ground in the Flathead valley, near the international boundary line, south of Fort Steele, is receiving attention, says the Fort Steele Prospector. There are two companies operating in Kintla Lake district. The oil found has a paraffine base. The Kintla Lake Co. has oil in its well at a depth of 1000 feet, but it is still sinking and expects to drill 2000 feet.

Nelson District.

It is stated work will be resumed on the Mollie Gibson mine, near Nelson, which was closed down a year ago by a snowslide. There is said to be ore in sight in the mine on the first, second, third and fourth levels. The mine has been opened by four tunnels. The lower one is 500 feet from the apex of the vein. The ore averages 60 ounces in silver and 15% lead.

Rossland District.

During the last fiscal year the Le Roi M. Co. at Rossland made a profit of $400,000, according to a statement made at the annual meeting in London. The financial statement for the year ended June 30, 1903, showed profits of $400,000. This was supplemented by the announcement that the January profits this year aggregated $50,000 net.

The report of the Le Roi No. 2 M. Co., operating at Rossland, for the year ending in September last, shows as result of year's working 31,100 tons of ore raised, of which 17,550 tons were shipped to the smelter, of an average value of $20.69. The cost of realizing on this amounted to $8.288 per ton, leaving net returns from smelters, $217,750. Since the termination of the contract with the Northport smelter in August, 1903, a contract has been made with a Greenwood smelter for treatment of the Josie output on more favorable terms. Shipments commenced on September 9 and returns for the current year up to December 31 show profits from shipments at the rate of $10,000 per month. The new oil concentration plant went into operation in November. So far it has only been considered advisable by the management to put through ore of low grade (averaging under $5), so as to enable those in control to gain experience of the working and technical difficulties of the process, says the director's report.

Slocan District.

Twelve men are working at the Cinderella-Medford mine near Sandon, and Cory & Foster, lessees, expect to ship one carload of ore per week while rawhiding continues.——The Queen Bess mine, in Idaho Basin, near Sandon, has been sold to W. E. Zwickey, G. Potter, R. Irving et al. The Queen-Dominion M. Co., Ltd., is being organized to operate the property. The Queen Bess, formerly owned by the Queen Bess Proprietary Co., is said to have shipped $250,000 worth of ore, which is galena and carbonates. A total of 2700 feet of tunnels and shafts have been driven.

Yale District.

H. Mayhew, of Flintshire, Wales, a director of the York and Lancaster Co., which owns the Alice group, near Creston, reports he has, with J. Hampton, leased the Alice group from the company, and intends to install a concentrator and an aerial tramway. It is a silver-lead group.

CANADA.

Yukon Territory.

Tacoma reports say the spring rush from the Pacific coast States to the new Alsek mining district, near White Horse, has started. Many men are going in with horses and outfits to engage in business or start mining. The diggings are 150 miles west of White Horse, and are reached by a rough trail over a gently rolling country. Official reports, covering the stakings in Alsek district, show that to Jan. 1, 1904, thirty-five creeks had been staked, with a total of 1500 claims. Two hundred and fifty claims have been staked on Bullion creek and 133 on Sheep creek. J. Potoker, from Alsek, reports prospects all along Sheep creek run from 10 to 20 cents per pan. The creek is full of water this winter at a greater depth than 10 feet, and bedrock cannot be reached. It is thought the district can be worked to the best advantage in summer by open-cut system. A movement from the Klondike and Atlin districts to Alsek has begun and roadhouses are being built.

MEXICO.

Chihuahua.

G. W. Boyce reports work progressing on the Senorita mine at Victorino. The shaft on the vein is down 80 feet and crosscutting is being done. Assays show twelve ounces silver. This ore body is said to be a mineralized dike, 9000 feet long, averaging 30 feet wide.

C. Barbier and F. Ramirez have started work on La Reina mine, near Cusihuriachic. As soon as sufficient ore is accumulated they will start the Burns mill.

Durango.

(Special Correspondence).—Several new railroad enterprises are in progress near Durango. The International Railroad is building toward Guanacevi, a silver camp. A competing line over nearly the same route is the proposed Parral & Durango Railroad, controlled by Americans operating mines at Parral. The object of this company is to tap the Guadalupe y Calvo district in Chihuahua and the gold and silver mines on the headwaters of the Sinaloa river. Another proposed line headed for Culiacan will connect with the short line now running from that point to the port of Altata, on the coast. Surveys of this line pass near the lead camp of Topia and the gold and silver mines of San Andreas. This route will open up the coal territory at the San Juan ranch, near Remedios, and pass near the gold and silver mines of La Trinidad and Bacis. Other surveys have been made from Durango to Tepic, passing through a section carrying gold, silver, lead and tin ores.

R. C. Kirk of Vivorillas has a plant at work pumping water from the workings on the Pueblito mine, on which he intends to do development work.——The number of men at the La Dura mine has been increased. The mine is a steady producer of shipping ore. The mine is near the Sinaloa-Durango boundary line and owned by F. Aragon of Cosala. F. Jarrold is superintendent.

Durango, Feb. 27.

Sinaloa.

(Special Correspondence).—The Barrateros mine, near Cosala, which was shut down temporarily, has resumed work. The tunnel which is being driven to tap the old Spanish shaft has attained a length of 760 feet. It is in a lime belt cutting through the coast granite.

Minney & Co. have completed their second cleanup at their mill at San Galindo, on the Elota river. They are testing the ores of the Mariposa (formerly La Trinidad) mine, near Guadalupe de Los Reyes.——T. Boland has men developing his claim on the south side of the Sierras Barrateros. The values occur in pockets of gray copper, running well in silver.

The Franco-Spanish M. Co., owning the Estaca and Descubriadora mines at Guadalupe de los Reyes, have a diligencia (stage) running between that point and the port of Mazatlan, making the distance in eighteen hours.——The old Santa Ana mine, on the Elota river, near the Durango line, has been denounced by the Mexican stamp agent at Cosala.

Cosala, Feb. 27.

Sonora.

The Greene Con. G. M. Co., W. C. Greene of Cananea president and manager, is preparing to put in machinery to operate on the San Miguel and San Domingo mines in the eastern part of Magdalena district. The property includes the Santo Domingo and La Busca placer fields.

G. W. Crowe, manager of the Ruby G. & C. Co., east of Ortiz, says the gold mines owned by the company are showing up satisfactorily. F. B. Wilson, of New York, is president.

Personal.

P. L. YOUNG left London on the 18th ult. for Valparaiso, Cbile.

A. H. JEREMY, a coal mine operator of Pittsburg, Pa., is in San Francisco, Cal.

L. A. STEVENS of Boston, Mass., is in Chibuahua, Mexico, on mining business.

L. T. BAKER of Britton, S. D., is visiting the Gold Bug mine, near Sumpter, Or.

F. N. HUBER, of the United States Geological Survey, is in San Francisco, Cal.

J. C. BRANNER of Stanford University, Cal., bas gone to Europe on a year's vacation.

B. B. THAYER succeeds Wm. Scallon as Montana representative Amalgamated Copper Co.

T. MCGREW is superintendent of the Great West mine near Chloride, Mobave county, Ariz.

C. M. LOVE, president of the New Vulture M. Co., is in Wickenburg, Ariz., from Cbicago, Ill.

H. FISCHER AND W. J. RAND of Boston, Mass., are examining mines near Wickenburg, Ariz.

F. J. HURNE, president of the Colorado Fuel & Iron Co., is in San Francisco, Cal., from Denver, Colo.

R. L. AND W. J. DOUGLASS, mining superintendents of Virginia City, Nev., are in San Francisco, Cal.

F. C. FINCKLE, cbief engineer of the Edison Electric Co. of Los Angeles, Cal., is in San Francisco, Cal.

J. A. BUNTING, owning extensive oil interests in California, is in San Francisco from a trip to Tyoah, Tex.

W. E. GRAY of Denver, Colo., has returned from Georgetown, Colo., from looking after mining interests.

E. F. PEARSON, manager of the Richmond G. M. Co., at Hillshoro, N. M., is in the East on company husiness.

MANAGER E. F. FREUDENTHAL of the Manhattan M. & S. Co. of Pioche, Nev., is in New York City on husiness.

H. SCHNITZEL of Lead, S. D., is manager of the Hidden Fortune G. M. Co., vice A. H. Danforth, resigned.

CAPT. WM. HART of the California Debris Commission has returned to San Francisco from San Andreas, Cal.

B. F. MONTGOMERY of Colorado Springs is interested in mining on Chicago creek, near Idaho Springs, Colo.

C. O'KEEFE has resigued as president and manager of the mines of the Sonora M. & M. Co. near Altar, Sonora, Mex.

E. C. VOORHEIS of the United States Assay Commission has returned to Sutter Creek, Cal., from Philadelphia, Pa.

J. J. TRENAM, manager of the Stockton and Beaver Con. mines, at Stockton, Utah, is in the East on mining husiness.

R. C. BONNEY is manager of the Sun & Moon mine at Idaho Springs, Colo. H. N. Simms resigned on account of ill health.

A. H. DANFORTH of Lead, S. D., has resigned as manager of the Hidden Fortune G. M. Co. and has gone to Colorado.

R. C. WILSON is superintendent of the Little Bully Hill group of mines at De Lan ar (Winthrop P. O.), Shasta county, Cal.

H. C. HANSON of Logan, Utah, manager of the Amazon M. Co., has gone to San Francisco, Cal., on company husiness.

C. S. ROBINSON of Cripple Creek, Colo., and E. S. Plumh of Colorado Springs, Colo., are examining mines in Mexico.

J. H. SMITH of Little Falls, N. Y., is president and manager of the Sonora M. & M. Co., operating in Altar district, Sonora, Mex.

HOMER WILSON of San Francisco, Cal., is in New York in the interest of the Wildman-Mahoney mines, of Sutter Creek, Cal.

G. W. CAMPBELL has returned to San Francisco, Cal., from the Black Oak mine, near Soulsbyville, Tuolumne county, Cal.

J. W. CARY, for the past three years with the Mine & Smelter Supply Co., Denver, Colo., has retired to look after other interests.

SUPERINTENDENT DENTON of the Trimountain and Baltic mines, near Painesdale, Mich., returned there last week from a trip to Florida.

A. F. NATHAN, manager of the Stilwell M. Co., operating in Mexico, has removed bis headquarters from Chihuabua to Mexico City, Mex.

R. E. STRATTON, superintendent of the Panhandle Smelting Co., has established headquarters at Sandpoint, Kootenai county, Idabo.

R. H. ROGERS of Springfield, O., interested in tbe Horshoe Bend Rancho mining property in Tuolumne county, Cal., is in San Francisco, Cal.

MARK MANLEY, superintendent of tbe Enterprise mine on East fork, near Coleridge, Trinity county, returned last week from a business trip to Boston, Mass.

J. M. HILLYER has been examining the Compio silver mine and adjacent gold claims near Guadalupe de los Reyes, Mexico, and is now at Panuco, Sinaloa, Mexico.

H. W. GOODE, president and manager of the Portland General Electric Co. and general manager of the Lewis and Clark Exposition, is in San Francisco, Cal., from Portland, Or.

C. BECKER, Denver, Colo., an assistant the past two years witb L. Humphrey with the Guggenbeim Exploration Co., has accepted management of a copper mine in Sinaloa, Mexico.

J. H. FENNESSY, treasurer of the Mine & Smelter Supply Co., Denver, Colo., will assume the duties of president of that corporation; Cbas. H. Tibbitts will be general manager and Albert H. Seep vice-president.

H. MAYHEW, colliery manager of the Harwarden estate, in Flintsbire, Wales, is visiting mines in Britisb Columbia in which he is interested, including the Alic group near Creston, B. C., and mines at Ymir. He will go to New York, N. Y., this week.

FORMER MANAGER MCLOUD, of the Abe Lincoln mine, in Poverty gulch, Cripple Creek, Colo., will manage the Bull Hill properties of the Stratton's Cripple Creek M. & D. Co., including the American Eagle, John A. Logan, Orphan May, Lucky Gus Kellie and Six Points.

F. D. WEEKS of New York, metallurgical engineer for the Engineering Co. of America, was recently in Denver, Colo., on his return from the Northwest, where he was making examination for the installation of a smelting plant. Mr. Weeks recently had charge of the installation of a large nickel plant in Sudbury, Ont.

PRESIDENT ALDERSON returned to Golden, Colo., from St. Louis, after arranging for the exhibit of the Colorado School of Mines at the fair and for the summer school there next summer. The space assigned to the Colorado School of Mines at St. Louis is 30x40 feet, diagonally opposite the mines and mineral huilding.

J. S. AND R. J. CARY, president and vice-president, respectively, of the Mine & Smelter Supply Co., Denver, Colo., bave retired from the firm and will hereafter look after their interests in Routt county, Colo., where tbey are interested in coal and other mining interests. The Mine & Smelter Supply Co. will continue in business as heretofore under new management.

Commercial Paragraphs.

W. H. COVERDALE & CO. have incorporated to do a general engineering and contracting business, with offices at 66 Broadway, New York City.

THE Burt Manufacturing Co., Akron, O., have sold the Jones & Laughlin Steel Co. a 30-inch exhaust head for their plant at Pittshurg, Pa.

THE marble used in the construction of the new fourteen-story huilding of the Merchants' Exchange, San Francisco, Cal., is from the quarry of the Columhia Marhle Co., Columhia, Tuolumne county, Cal.

G. W. PENNINGTON & SONS, INC., of No. 313 Folsom street, San Francisco, Cal., report their shops in full operation, filling orders for their hammered steel shoes and dies. They also manufacture cam and crank shafts, rock breaker plates, refined tool steel, hammer, pick and machinery steel, and other forgings.

THE California Gas & Electric Co. of San Francisco, Cal., has bought the Standard Electric Co. and the United Gas & Electric Co., ahsorhing both corporations and becoming the largest institution of the kind in this west half of America, taking in twenty-nine different companies. The electric lines are over 1000 miles in length. The company is now producing ahout 45,000 H. P. and proposes to create 33,000 H. P. additional.

Trade Treatises.

Bulletin L-508 of tbe Laidlaw-Dunn-Gordon Co. of New York tells about the improved Cincinnati air compressor. It will be sent upon application to any one interested in air compressing machinery.

The Weinman Machine Works, Columbus, Ohio, send their general catalogue of pumping machinery for 1904, describing and illustrating their steam pumps, together with considerable technical information of general interest.

Obituary.

J. T. GRAYSON, formerly of Cincinnati, Ohio, but lately of Portland, Or., interested in Oregon mines, died at Cincinnati, Obio, on Feb. 25tb. Deceased was general manager of the Alpine Con. G. M. Co.

Latest Market Reports.

SAN FRANCISCO, March 4, 1904.

METALS.

SILVER.—Per oz., Troy: London, 26 1/16d (standard ounce, 925 fine); New York, bar silver, 57 3/8c, refined (1000 fine); San Francisco, 57 1/2c; Mexican dollars, 46 1/2@47 1/2c San Francisco, 45 1/4c New York.

COPPER. — New York: Standard, $12.50; Lake, 1 to 3 casks, $12.50; Electrolytic, 1 to 3 casks, $12.37 1/2; Casting, 1 to 3 casks, $12.25; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 15s spot per ton.

LEAD. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4 3/4c 1000 to 4000 lbs.; pipe 6 1/2, sheet 7, bar 5 3/4c; pig, $4.85. London: £11 17s 6d ℔ long ton.

SPELTER.—New York, $5.15; St. Louis, $5.00; London, £21 15s ℔ ton; San Francisco, ton lots, 6 3/4c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.00 @ 28.40; San Francisco, ton lots, 30 1/2c; 500 lbs., 31c; 200 lbs., 31 1/2c; less, 32 1/2c; bar tin, ℔ lb., 35@37 1/2c. London, £124 6s 7d spot.

PLATINUM. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75 @ 82c ℔ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ℔ flask of 76 1/2 lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 1/2c; extra, 17 1/2c; genuine, 31 1/2c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumhers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

LUMBER. — (Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50 @5.00; pickets, $21.00; shingles, $2.50 for No. 1 and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00 @35.00.

NAILS.—This week the hasic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ hhl.

CEMENT.—Imported, $2.15@2.40 ℔ hhl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ℔ hhl. in sacks, 4 sacks to hhl.

STRUCTURAL MATERIALS.

IRON.—Pittshurg, Bessemer pig, $13.60 @13.60; gray forge, $12.60; San Francisco, bar, 3c ℔ lb., 3 1/2c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, har, 7c to 12c ℔ lb.

GENERAL SUPPLIES.

ANTIMONY. — New York, Cookson's, 7c; Hallett's, 6 1/2c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8 1/2c; 100-lb. lots, 10 1/2c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15 1/2c; less than one ton, 17 1/2c. No. 1*, 60%, carload lots, 13 1/2c; less than one ton, 15 1/2c. No. 1** 50%, carload lots, 11 1/2c; less than one ton, 13 3/4c. No. 2, 40%, carload lots, 10c: less than one ton, 12c. No. 2, 35%, carload lots, 9 1/2c; less tban one ton, 11 1/2c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE. –Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet aud up.

CANDLES.—Granite 6s, 16 oz., 40s., 11 1/2c ℔ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23 1/2c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3 1/2c per lb.; caustic soda, in drums, 3@3 1/2c ℔ lb.; Cal. s. soda, hhls., $1.20@1.40 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, hbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2 1/2@2 3/4c; powdered sulphur, 2@3c; flour sulpbur, French, 3 1/4@3 1/2c; alum, $2.00@2.25; California refined, 1 3/4@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5 1/4@5 1/2c; cbloride of lime, spot, $2.50@2.75; sulphuric acid, in carhoys, 66% B, 1 3/4@2c ℔ lb.; nitric acid, carhoys, 8c ℔ lb.

BONE ASH.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.00; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymho, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumherland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, hbl., 49c; cs., 54c; raw, hbl., 47c; cs., 52c; Lucol oil hoiled, hhl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 20 1/2c; Astral, 20 1/2c; Star, 20 1/2c; Extra Star, 24 1/2c; Eocene, 23 1/2c; Elaine, 26 1/2c; Water White, in hulk, 14c; Mineral Seal, iron bbls., 19c; wooden bbls., 21 1/2c; cs., 25c; Mineral Sperm, cs., 26 1/2c.; Deodorized Stove Gasoline, hulk, 16c; do., cs., 22 1/2c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19 1/2c; Lard Oil, E W. S., hhl., 85c; cs., 90c; Neats-foot Oil, pure, bhl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6 1/2c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 1/2c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, 1/2c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6 1/2c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb., 6 1/2c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

BISMUTH.—Subnitrate, ℔ lb., $2.00.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—$2.00 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., $1.00.

PHOSPHORUS.—American, ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c: 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittshurg.

URANIUM.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Dividends.

On the 1st inst. the Bunker Hill & Sullivan M. & C. Co. declared a dividend of $45,000, payahle on the 4th.

Some of the Mines of Arizona.

About 12 miles in a southerly direction from Prescott, Yavapai county, Ariz., is the summit of Las Prietas mountains, which extend in an easterly and westerly direction between the Hassayampa river and the Agua Frio. The country from the vicinity of the base of the mountains northward is granitic. The rocks of the range itself are mostly metamorphic. The dominant point in the range is Mount Union, which has an altitude of about 7500 feet, though this summit is not very noticeably higher than the surrounding ridges. The slopes are rounded, and those of the main range are covered with a dense growth of chaparral and other brush, with scattering pines. The granitic area supports a magnificent pine forest. From the direction of Prescott a high, rough ridge of eruptive rocks, known under the general name of porphyry, joins the Prietas range in the vicinity of Mount Union.

The entire region of Las Prietas, from its most easterly to its most westerly limits, is recognized as a mineral country of promise. Along the western spurs are numerous gold and silver-bearing veins which have been worked with more or less success. Among these are the Catoctin, Dos Oris, Blue Dick, Ohio and Jersey Lily. Farther eastward, and near the contact of the granite and the metamorphic rocks, are a number of mines and prospects, some of which are attractive. Some years since a shoot of very rich gold rock was taken from the Howard mine, near the Hassayampa, under the shadow of Mount Union. The quartz was snow-white, with abundance of bright, native gold. The most noted mine on the range is the Senator, near Mount Union. This property has been extensively developed and is equipped with mill and operating plant. There are several groups of mines in the vicinity, among them being the Snowstorm, the Cash and the Grubb properties. The Cash is equipped with two steam hoists over shafts 500 feet and 700 feet deep, respectively, and it also has a 10-stamp mill. The other properties of the immediate vicinity are in the development stage. Farther eastward are the mines of the Walker district, at the head of Lynx creek, and the mines of Poland, Provideuce and Big Bug districts. Other mines of the vicinity are described elsewhere herein. Although these mines have been known for years, it is only recently, comparatively speaking, that the conditions were favorable to their operation. This is chiefly due to the complex nature of the ores. These generally consist of the sulphides of iron, zinc, lead and copper, with gold and silver, in a quartz gangue. This renders the metallurgical problem difficult of solution at a distance from railroad transportation, but the energetic mine operators of the district are solving this problem, and the promise of additional railroad facilities, either electric or steam, tends to aid materially in the solution of the economic problem. The mines for the most part occur in fissures in the highly metamorphosed shales—now deuse, hard slates—and are almost universally accompanied by intrusive dikes of felsite or porphyry. In some iustauces the intruded igneous rocks are also mineral-beariug. It is said of some of these ores that a considerable portion of their gold is amenable to amalgamation on plates in the stamp mill. The tailings are concentrated and shipped. In past years a number of the mines of this vicinity have profitably shipped their high-grade sorted ores to Colorado for treatment.

Cash Mill, Mount Union, Fifteen Miles Southeast of Prescolt, Arizona.

The Coming Power.

The great motive force in mining in the future will, without doubt, be electricity. This power has already been successfully applied to various branches of the mining and metallurgical iudustries, but that the best or ultimate results as to effectiveness or application have been reached, or even approached, is not believed by those competent to judge—nor would it be in keeping with progress to entertain such an idea. In transportation, lighting, and the transmission of messages or signals, electricity has reached a high degree of usefulness, and it has also successfully eutered the field of practical mining in the operation of compressors, mill machinery, hoisting engines and rock drills. In metallurgy it is also being successfully employed, but far greater advances in this direction may be anticipated. In the mining regions of the West electric power plants are already numerous and are constantly increasing in number. Within the past week a compauy has been orgauized at Salt Lake City, Utah, under the laws of Idaho, the purpose of which is to utilize the power of Shoshone falls, on Snake river. It is the intentiou to build three power plauts, the aggregate power of which it is estimated will reach 80,000 H. P., which will be distributed to mines within a radius of 200 miles.

THE Peruvian Governmeut has issued an order withdrawing deposits of borax and niter from appropriation by deuouncemeut under the mining laws, reserving these for the benefit of the Government, it being the evident intention of the Government to either exploit deposits of this character or to dispose of them to the highest bidder, thus realizing a considerable income from them.

Proposed Mining Law.

A new feature in mining law is contemplated in the recommendation by the Senate Committee on Mines and Mining of a bill introduced by Senator Heyburn of Idaho, providing for jury trials of cases wherein patent applications are adversed, the idea being to have the trials come before a court of competent jurisdiction instead of before the land office, as has been the custom in the past. This will permit of those who are personally informed as to the date and character of the location and the monuments of the claim, acting as witnesses in such suits. It is believed that this course will in a great measure do away with the unsatisfactory operation of these cases, and permit the facts to be arrived at without delay, while giving the court and jury an opportunity to judge of the character of witnesses, which is impossible where the trial is held at a long distance from the mine in question, and where the principal witnesses make no personal appearance, but merely send in their depositions. Should this bill become a law it will to a great extent remedy the troubles arising over the practice of the land department of insisting that the calls of the deputy United States surveyors shall take precedence over the monuments on the ground in determining the actual position of a claim.

AN interesting contention has arisen over the ownership of an Alaska mine at Nome, which is represented to have produced $1,300,000 within the past five years. The matter is being heard before a board of arbitration in Chicago, Ill. The contestants are a Swedish church, known as the Swedish Evangelical Mission Covenant of America, on one side, and a mining corporation and several individuals on the other. It is claimed by the church society that one of its missionaries staked the claim years ago when acting as agent or missionary for the church, and they contend that, as he was an agent of the church society, the property properly belongs to the church. The locator also says he located the mine for the church. This claim is being vigorously contested by the opponents to this somewhat novel theory of location by agent.

Mining Without Timbers.

The necessity for the practice of closer and still closer economies in mine management has led to the introduction of innovations in the practical operation of many mines. Forty or fifty years ago only small mines could be successfully operated, because no method of supporting the ground was known, where the "pillar and stall" method was inapplicable. In 1860 the square-set method was introduced and proved a boon to the managers of great mines everywhere. At first the square-set method was employed with the timbers alone to support the back of the stope or hanging wall, or both, but numerous disastrous caves resulted. The filling of timbered stopes followed and is to-day generally recognized as the best and safest practice throughout the mines of the world, and there are numerous large mines which can be successfully operated in no other way than by the square-set system of timbering and contemporaneous filling. There are various modifications of the square set, in which the method of framing the timbers and the manner of placing them represent the principal features of difference. In some systems the timbers are all framed on the surface and are placed without delay in the stope when required. In others the timbers are only partially framed on the surface, and when it becomes necessary to place them much hewing with an ax and adz underground is required—an expensive method. In some systems the ties of the square set are replaced by two "sprags"—one connecting the upper and one the lower post of two adjacent sets. Beside these there are many other modifications, but none of them are superior to, or less expensive, than the regulation Nevada sets. In some regions when mining is first commenced, timber is abundant and comparatively inexpensive, but as years go by the timber supply becomes scarce and consequently costly. This has been the experience in numerous regions. But what of semi-arid and desert regions, like those of the Rand, South Africa, Australia, and some of the regions of Mexico and the United States? Timber is always a large item in the expense of mine operation, and particularly so in timberless regions. This has led to various experiments in mining with less timber than is required in the square-set method. These efforts have resulted in the evolution of several methods by which large bodies of ore are extracted by the use of a minimum amount of timber. With this issue of the MINING AND SCIENTIFIC PRESS is concluded a series of valuable articles on mining methods at the Homestake mine, Lead, South Dakota. The methods introduced the past few years are not widely different from those in use at the Broken Hill mines in New South Wales, Australia, and somewhat similar methods are being introduced at the Mount Morgan mine, Queensland, Australia, and elsewhere. These methods are applicable to those mines where the ore bodies are large and the rocks firm. Ground which caves easily would generally be considered unsafe to mine by these methods, and in such cases the full square set, with filling, must be resorted to. The methods in vogue in the iron mines of the Lake Superior region, Michigan, and in Minnesota, are also valuable, and illustrate a somewhat different practice. These methods, and particularly the "caving system," are not always readily applicable to precious metal mines, as there often exists too little difference in the physical appearance of ore and waste rock in the latter to make a separation of the valuable from the valueless easily possible. Where iron ore is to be separated from sandstone the problem is simplified, and the ore can easily be separated from the waste. In each mine the manager or superintendent must study out the conditions under which he is operating and strive to utilize all the natural advantages, and to minimize those conditions which are against him, and the result will usually be an improvement on old systems and a lessening of costs. Because some particular method has been in use for forty years is not a good reason for not making intelligent experiment and evolving an innovation occasionally which will redound to the credit of the manager who dares to try something new, and which was unknown to his ancestors.

Premature Installations.

In former years, when the science of mining was less thoroughly understood than at present, there seemed an excuse for prematurely building a reduction plant at an undeveloped mine; but in these days there seems little to justify such a mistaken step, yet this is of frequent occurrence. Prospects are taken up by corporations at the suggestion of promoters, and, although the property may have only limited development, and while there still exists great uncertainty as to the amount and value, as well as the character of the ore which may be developed in the future, great smelters and mills are built at a cost too often reaching into hundreds of thousands of dollars, when one-fourth of this amount legitimately expended in the development of the mine may show the uselessness of the plant, for the reason that it is unsuited to the ore, if, fortunately, there be ore to treat. In some instances a successful man finds himself embarrassed through having accepted a position with a concern presumed to be responsible, but without having first made inspection of the property. In such instances the unlucky superintendent may find he has a large smelter or mill to supply and no mine to furnish the ore. In another case he may find abundance of ore, but of a character requiring a wholly different equipment than that which has been provided. In a third instance, and probably the most usual of these cases, he finds abundance of ore and suitable plant, but too little value to make it possible to derive a profit from its operation. Fortunately, such cases are becoming more and more rare, as experience in mining accumulates; but such instances still occur. Sometimes they are the result of unscrupulous promotions, but more frequently are because of the overconfidence of the owners, or the inexperience of the superintendent. The man who has once put up a mill before getting his mine can be pretty surely counted upon not to do so again. The world sneers at him; his friends laugh at him; but some sympathize with him. His eagerness, optimism and energy are needed to help the world along. But the loss, chagrin and humiliation which he suffers are such bitter lessons that he is liable to be too cautious rather than too rash in the future. Mine owners and mine buyers are beginning to understand that the estimation of the amount of payable ore in a fairly developed mine is no longer guess work, and that it pays in the long run to have their mines carefully, patiently, faithfully sampled—and this by disinterested persons, too—assay plans made, and the tonnage estimated therefrom by competent mining engineers before the erection of works. In the same way that insurance is found to pay—by protection against the chances of loss—so in mining it pays to cut the ore up into blocks by levels and winzes, even though the cost be considerable, and have it thoroughly sampled.

THE official reports of several copper mining companies operating in the Keweenaw peninsula, Michigan, show that a substantial profit can be made in mining and crushing ore containing less than 1% copper per ton. The copper is all in the form of native metal, usually occurring in disseminated grains. This is freed by the crushing and concentrated, the concentrates containing over 70% metallic copper, which is smelted in the furnaces and shipped as copper ingots. The ratio of profit to output is small, still the net result is satisfactory, and the past year has shown that with improved methods and machinery it is possible to derive a profit from a lower grade of ore than has ever before been obtained.

THE bill introduced in Congress providing for the return of money remaining unexpended from deposits made with the Surveyor General to cover expense of platting and office work in connection with patent proceedings of mining locations, has been reported favorably by the Senate Committee, with the recommendation that the bill become a law. As the law exists, a stated amount must be deposited in all cases, though the expense in some is much more than in others. It is the object of the proposed legislation to have all unexpended money of each deposit returned to the applicant. The defect in the present bill was long since recognized, but the land office has made no effort to remedy the matter.

CONCENTRATES.

THE sample of metal sent from Sumpter, Or., is gold, plated with quicksilver. By heating the mercury will all disappear, leaving clean gold.

✣✣✣✣

THE mineral specimen from Alameda county, Cal., is chromic iron. The green scales are not copper, but magnesian material, stained green by chrome. It occurs in serpentine.

✣✣✣✣

RED OXIDE OF COPPER is the richest copper ore known, containing when pure 88.8% copper. If no reduction works are at hand, it should return a good profit by shipping to a smelter. It is not used in refining petroleum.

✣✣✣✣

IT is unwise to sink a shaft in a gulch, even if the dump eventually surrounds the shaft and raises the collar above the immediate drainage. Unless a concrete dam be built around the shaft, the drainage of the gulch will to a great extent penetrate the dump and flood the shaft.

✣✣✣✣

THE mineral sample from Olalla, B. C., is metamorphic shale, containing a small amount of pyrite (iron sulphide) and of pyrrhotite, a sub-sulphido of iron, slightly magnetic, also a very small amount of the copper-iron sulphido chalcopyrite. The dark mineral is pyrrhotite.

✣✣✣✣

THE rocks from Mancos, Colo., are: No 1, rhyolite, the quartz is microscopic; No. 2 is felsite, a feldspathic igneous rock: No. 3 is similar to No. 2, but contains finely disseminated marcasite (white iron sulphide); No. 4, quartzite, with some marcasite and calcium carbonate, the latter incrusting; No. 5 is hornblende, and No. 6 is basalt.

✣✣✣✣

A SECURE CRIB DAM may be made in even a torrential stream, if a solid foundation can be found. It is customary, if there are no large reefs of rock to tie to, to cut an excavation in either bank and to build cribs in these excavations, filling them with rock—the dam proper being constructed between the cribs and firmly built into them.

✣✣✣✣

WHEN a vein is found faulted it is not always possible to tell in which direction the "throw" has taken place. Particularly is this the case where the rock on both sides of the fault are of the same character, such as granite. Often the plane of the fault is not sufficiently clean to admit of careful measurement of angles, and then approximations only are possible.

✣✣✣✣

THAT there is any difference between fissure and true fissure is not clear. A fault fissure is essentially the same as any other fissure, except that in the case of a fault fissure there may have been some movement of the walls relatively to each other. No particular type of fissure vein is more indicative of value than any other kind. Some of the most perfect fissure veins are without ore of value.

✣✣✣✣

A MINER or other employe of a mining company or corporation, who does not hold a position of trust involving confidential relations with the company employing him, may locate a claim for himself or for another as agent at any time when not "on shift," as when off shift his time is his own to spend as he sees fit. A claim on any other than unoccupied Government land open to location is void.

✣✣✣✣

ONE cubic inch of steam will expand 1728 times, or to about 1 cubic foot. It is this property of steam that makes it valuable as a creator of motive power. The explosion of gas in engines acts in the same manner. Upon the explosion taking place the material expands to many times its original volume, and, in the same manner as steam, drives the piston from one end of a cylinder to the other.

✣✣✣✣

THE lead-silver mines of Resting Springs, in eastern San Bernardino county, Cal., were worked nearly forty years ago. A large amount of ore was shipped across the desert to San Pedro, Cal., via Los Angelos, and thence shipped to San Francisco for treatment. A smelter was built at the mines, but owing to excessive cost of treatment was closed down, and the mines have since remained idle.

✣✣✣✣

WHEN a blast furnace is in proper working order the region of highest temperature is at the zone of combustion in the vicinity of the tuyeres—about 2000° C. There is a decrease in temperature from this point upward toward the top of the charge, where it is usually 100° C. or more. Where the ore column is very high and little carbonaceous fuel is employed, as in pyritic and semi-pyritic smelting, the temperature at the surface may not exceed 40° C.

✣✣✣✣

WHERE a drain tunnel has been driven under a shaft, and the water still remains in the shaft or shows only a small amount of drainage, it is probable that the crevices of the rocks have become filled with fine clay or silt, and this material is rendering the seepage of water through it slow and difficult. If the shaft be bailed out it may improve matters somewhat, as the splashing of the water about the shaft would have a tendency to dislodge the silt and re-establish the flow of water through the rocks.

✣✣✣✣

IF, in the operation of a mine, the workings, in their downward extension, pass beneath the lands of another and buildings or other structures, reservoirs, etc., are destroyed or damaged by reason of subsidence of the ground, due to caving of the mine workings beneath, the mine owner is responsible for such damage: Humphries vs. Brogden, 12 A. B. 739; also Carlin vs. Chappel, 101 Pa. St., 47 Amer. Rep., 722. The owner may not set up the defense that he worked the mines in workmanlike manner.

✣✣✣✣

THE cost of handling ores in a reverberatory furnace depends upon a great many conditions. The size of the furnace, kind of fuel used, character of ore and whether the ore is stirred by hand or mechanically stirred, all share a direct and important influence on cost. Crude petroleum as fuel is superior to either wood or coal, for the reason that the process of roasting can be carried nearer perfection with oil than with the other fuels mentioned, and the heat is always under control by properly manipulating the side doors of the furnace to admit a greater or less amount of oxygen.

✣✣✣✣

IT is good practice to put the cap in a charge of nitro powder 3 or 4 inches below the top of the charge. Placing it near the bottom of the charge has no advantage, and there is a possibility of setting fire to the powder from the burning fuse before the fire reaches the exploder. It is better to put in tamping, though the blast will do nearly as good execution without it. It need not be tightly rammed. Water poured into the hole will answer, provided the cap is properly protected. A bar of metal must not be used in tamping any kind of powder, as it is dangerous. Picking out missed holes is also very dangerous, particularly as long as the cap remains in the hole.

✣✣✣✣

THE rocks from Daggett, Cal., are: No. 1, liparite (a variety of rhyolite); No. 2, pearlite (volcanic glass); No. 3, hornblende andesite; No. 4, rhyolite tuff; No. 5, rhyolite breccia; No. 6, sandstone, composed wholly of volcanic grains; No. 7, colemanite (calcium borate), and is a mineral, not a rock; No. 8 is jasper, containing flakes of horn silver; No. 9, mica schist; No. 10, nevadite, a variety of rhyolite, resembling granite in physical appearance; No. 10 is shale (volcanic mud); No 11 is baryta (heavy spar); No. 12 is marble (calcium carbonate), with a little gold; No. 13 is iron oxide, surrounding a nodule of copper-silver glance, with copper carbonate about the glance; No. 14, shale, containing a fossil of Tertiary age.

✣✣✣✣

THE mineral specimens from Copperton, Zuni mountains, New Mexico, are: No. 1, typical quartz porphyry, containing crystals of pink orthoclase and blebs of vitreous quartz: there is also present a small amount of malachite (green copper carbonate). No. 2 is the result of alteration of No. 1. It shows schistoso structure, but the quartz blebs are still plainly seen. Some silica has been infiltrated, and copper carbonate is more abundant than in No. 1. The rock has been deformed by pressure and movement, causing the rock to be "stretched" and sheared with subsequent alteration of the mineral constituents. No. 3 may be considered an intermediate stage of alteration between Nos. 1 and 2. It also contains a little copper carbonate.

✣✣✣✣

TAILINGS may be used to advantage in filling the stopes of a mine if the tailings are first dried, and there be no water in the mine. Should the pile of sand become wet after having been placed in the stopes, it would be difficult to anticipate the result. The sand would run through every available crevice, filling all open workings, and prove to be a nuisance and source of expense, instead of a benefit. There are many mines having large waste dumps on the surface, which could be made available for filling by driving a raise into the pile or near it, through which the waste rock may be allowed to run down into the mine. This can generally be accomplished at small cost—that of driving the raises, and the cost of filling per ton of ore extracted would be but a few cents per ton.

✣✣✣✣

THERE is a wide range in altitude of the ore deposits of Leadville, Colo., there being as great a difference in elevation as 2000 feet, caused by a series of step-faults. The ore bodies were formed at a depth approximating 10,000 feet, according to S. F. Emmons, and were subsequently uplifted and the overlying rocks eroded by glaciers and otherwise down to the region of mineralization. The several prominent hills of Leadville, Fryer hill, Carbonate hill, Iron hill, Breece hill, Prospect hill, etc., all owe their existence to a system of faulting, which has lifted each particular block to separate elevations, the hills all being rounded by subsequent erosion, there being no abrupt surface indication, such as a bluff or scarp, of the existence of faults along the lines of the several displacements. A large portion of the lower area is covered with the debris of a glacial lake bed.

✣✣✣✣

CONVERTER LININGS are made from a mixture of quartz and clay, the former being the essential material, the clay being employed as a binder to hold the quartz fragments together so that they may withstand the destructive force of the blast and also the surging of the molten charge in the converter. For this purpose the quartz is run through a breaker and both coarse and fine fragments (the largest about five-eighths inch in diameter) are mixed together with the clay. If all coarse rock be used the lining will not stand well. In a large converter nearly 10,000 pounds of lining are required. It is the opinion of experienced copper smelters that the less clay that can be used to hold the lining together, the better. The clay must be of good quality—plastic, but not necessarily "fire clay." The lining is placed in the converter and rammed with a heated bar of iron. The ramming must be done with care and should be done by experienced men. After ramming, the convertor should be thoroughly and slowly dried. Haste to use a newly lined convertor will generally result in the prompt necessity for relining.

✣✣✣✣

NATURAL VENTILATION in mines is superior to any other kind; but some mines are so situated or developed, having only a single exit, that natural ventilation is reduced to a minimum, and, as a result, unless artificial ventilation is provided, the mine is poorly ventilated. Where a shaft is connected with a tunnel, the direction of the current of air will be determined by outside conditions. If the column of air from the tunnel level to a height equal with the collar of the shaft be warmer and lighter than the air in the tunnel and shaft, the heavier column will fall and the air will flow down the shaft and out of the tunnel. At night, or in winter, or at any time when the column of outside air is colder and heavier than that within the mine, the direction of air current will be reversed and the shaft becomes an up-cast. Occasionally the direction of air current is constant in mines where two or more shafts are connected, and, through some cause, the direction of current is changed and continues in the newly established direction. It is said that at the Yellow Jacket shaft on the Comstock Lode, Virginia City, Nev., the shaft was a down-cast and had always been such since connecting with adjoining mines, but that a fire in the mine changed the direction of current and the shaft thereafter was an up-cast. It is probable that in such a case the columns of air must have been very nearly balanced and required little to change it.

✣✣✣✣

TELLURIUM was discovered in 1782 by M. von Reichenstein, in gold ore from Transylvania, Austria. It is a brittle, silver-white metal, having a specific gravity of 6.25, resembling sulphur in its degree of volatility. When in combination with gold, upon roasting it causes a loss of gold due to volatilization greatly in excess of that occurring when gold is melted alone. It has very high electrical resistance. Metallic tellurium is produced by mixing 300 pounds of ore containing about 3% tellurium with 700 pounds of sulphuric acid at 66° B., in a cast iron pot, and boiling for several hours. Twenty-four hours later the liquid is poured into a lead-lined vat where sixty-five gallons of hot water are added. During the following six hours forty pounds of commercial hydrochloric acid are mixed in. After standing another twenty-four hours the mass is run through a filter press, and the tellurium solution passes to a lead-lined tank having a tight cover, where it is treated with sulphurous acid for three days, during which time the tellurium is precipitated in metallic form. This is continued until no precipitation occurs on testing with sodium sulphite. The commercial value of tellurium per pound is about as follows: For 30% pure, $10; 60%, $12.50; 80%, $16. Fused tellurium containing 94% to 97% of the element is worth $35 per pound. Tellurium occurs native, but is more commonly associated with gold, silver, lead and bismuth, also less commonly with nickel (melonite).

✣✣✣✣

IN exceptional cases the wages paid a watchman to take care of machinery and to look after the timber in an idle mine, making repairs, etc., may be counted as money spent on annual assessment, but in such cases it must be shown that work is to be resumed. Concerning this the Supreme Court of California said: "The cases must be rare in which it can justly be said that such money is expended in prospecting or working the mine. There may be cases where work has been temporarily suspended, and there are structures which are likely to be lost if not cared for, and it appears that the structure will be required when work is resumed, and that the parties do intend to resume work, in which money expended to preserve the structure will be on the same basis as money expended to create them anew. But this could not go on indefinitely. As soon as it should appear that this was done merely to comply with the law and to hold the property without any intent to make use of such structures within a reasonable period, such expenditure could not be said to have been made in work upon the mine. Much less could the mine owner bring picks, shovels, and things of that kind, upon the mine, and have some one to watch them to prevent them being stolen, and have such cost of watching considered as work upon the mine." "Expenditures made in unwatering a mine might be considered in estimating annual work," says Lindley on Mines, "if such unwatering was for the purpose of resumption of active operations. But where this class of work was done for the sole purpose of having an expert examination made preliminary to a proposed sale, we do not think such expenditure should be allowed."

Some Features of Mining Operations in the Homestake Mine, Lead, South Dakota.

NUMBER V—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by BRUCE C. YATES, E. M.*

HOMESTAKE SYSTEM.—However satisfactory this method of blocking out the ore body may be, it did not solve the timber problem. After much deliberation and discussion it was decided to try stopiug in these rooms without timbers. Again the practical ideas of the mine foreman and his assistants worked ont a system which seems to be well adapted to the conditions existing iu the Homestake mine, and which for the sake of convenience has been called the "Homestake System of Stoping."

The level is opened by the room or block method and sills are laid in the rooms the same as for timbered stopes. When the sills are in, three lines of track are laid running leugthwise of the stope, but crossing the ledge with as many cross tracks connecting them as are necessary. The sill-floor sets are put np and lagging placed over the top. The tracks are protected by double lagging on top and the rock is prevented from runniug in, at the sides, on to the tracks by lagging or slabs spiked to the posts.

As soon as the timber is in position the mining operation begins. The ore is broken down and allowed to fall through the lagging, entirely filling the sill-floor sets, with the exception of the carways. The lagging, which serves merely as a staging, is removed as fast as the sets are filled with broken ore. No rock is removed from the stope until this filling is finished. When the next cut or breast is carried across the stope some ore mnst be removed to make room for the miners.

In the large stopes two D-24 Ingersoll machines are employed, with from one to two "baby" machines, which are used to drill blockholes in the large bonlders.

Somewhat of an innovation in machine drills for blockholing has beeu introducecd. A small pneumatic hammer, such as is used in shops for chipping and caulkiug, fitted with a rotating movement, operates a small drill bit about 1 inch in diameter. This machine will drill holes from 6 inches to 12 inches deep, and has so far proven very sncccssfnl in blockholing large boulders in the open stopes.

As there are no timbers to break, no limit is placed on the miner as to the amonut of rock he may bring down at one blast. The stope shonld be finished as quickly as possible so that the broken rock may all be removed if needed. Consequently large slabs of ore are blasted down and these mnst be broken np to regular car size either on top of the pile or on the sill-floor as it is drawn down by the shovelers.

Ou acconnt of the uneven size of the rocks chntes are not generally used in these stopes, but the car men shovel the ore into cars from the level of the track, there being as many places to shovel from as there are spaces between posts along the track. However, where the rock is soft and where it breaks fine, chntes are used to advantage.

Should a large rock come down which the shovelers cannot break with a rock hammer, he moves his car to another opening uutil the "blockholer" comes around.

Two or three regular sets on each side of the stope are carried np as fast as the stope is worked, in which are placed the ladders and air pipes. These open sets also assist in ventilating the stope.

*Copyrighted.

When the stope is worked np 80 or 85 feet raises are made to the level above through which the filling is to be dumped, and the ore is then drawn out. While the ore is being drawn ont the walls and roofs are carefnlly watched and all loose material is dressed down. No accident of a serious nature has occurred in one of these stopes during the two years in which this method has been employed that could in any way be attributed to the method.

When one end has been emptied of ore a section of the sill-floor is lagged aud the filling is dumped in until it begins to run over the lagging. In this way the filling follows the shovelers and the walls of the stope are snpported at one end by the ore and at the other by the waste.

When small ore bodies are worked bv this method no pillars are left in, but when one section is worked np a snfficient height another section is started at one end and the ore is left in until the entire body is worked.

Stoping without timber is not confined to the Homestake miue, but there are certain featnres of the method as employed here peculiar to the Homestake, and which are considered necessary to suit our conditions. In the Treadwell mine the sill-floor is not opened on the station level, but drifts are run in the ledge and raises put up from these drifts to a level some 15 feet above.

No timber is required except for chntes, but a back of ore is left in, which takes the place of the sill-floor timbers used in the Homestake. The cost of the timber would, in a great measnre, be offset by the cost of making raises and pntting in chutes. The accessibility of the ore is another advantage in favor of the Homestake method and becomes a necessity in a mine which furnishes nearly 4000 tons of ore every twenty-four hours.

As only a small per cent of the ore can be removed before the stope is finished there is of necessity a large reserve always on hand, which allows the mine to lay off whenever desirable. The present broken ore reserve in the mine is nearly 1,000,000 tons.

Another plan of working these stopes is now being carried out by which at least 50% of the sill-floor timbers will be saved. Instead of the two outside tracks being in the stope a drift is cnt under the edge of each pillar of sufficient height and width to receive one line of regular stope sets, and tracks are laid in these. The timbers are pnt in place and the ore is broken down until the sill chamber is partly filled, the broken rock holding the timber sets in place. An opening is made iu the broken rock through the center of the stope in which another line of sets is put up, the loose rock being shoveled back

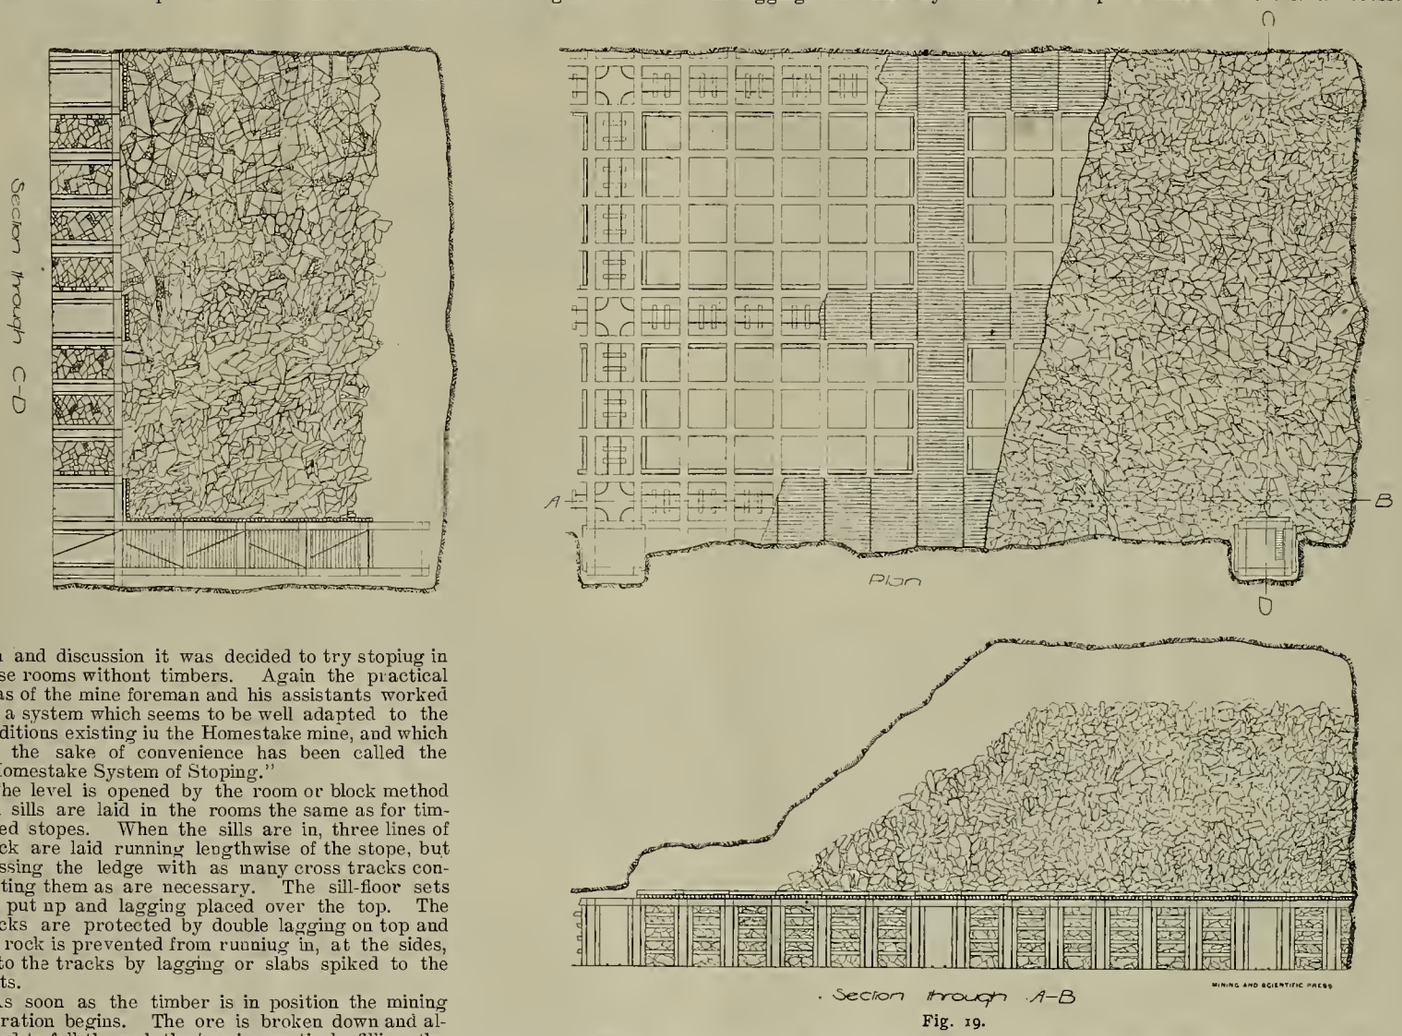

Fig. 19.

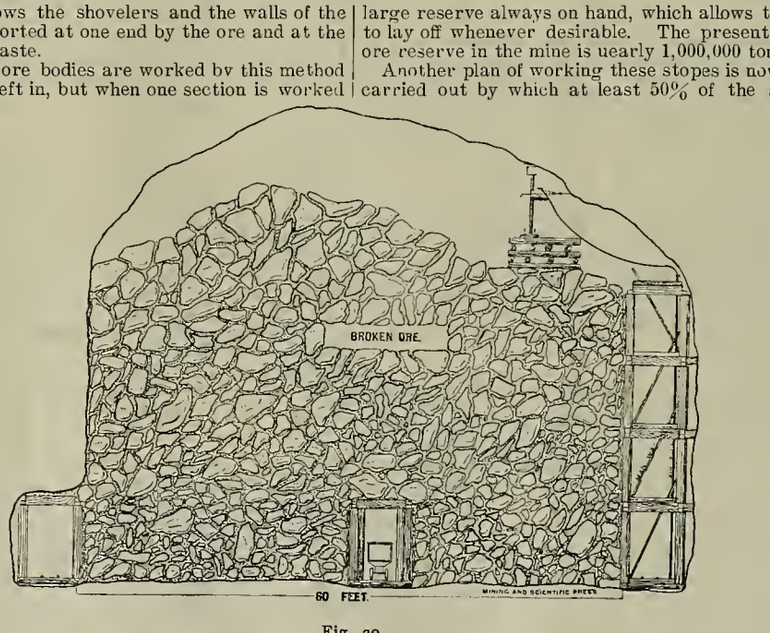

Fig. 20.

against the posts to support them. No sills are laid between the rows and only six rows of posts are required, whereas eleven rows are required in the other stopes. The tracks will be laid in these open sets and the two under the pillars may be used again when the pillar is being taken out.

Following is a comparative table giving the cost of timber in a stope which has been worked and timbered by square sets and the same stope if worked by the Homestake method:

TIMBERED STOPE.

Name of Piece.	Number of Pieces.	Linear Feet or Feet Board Measure.	Cost of Material.	Labor, Sawing and Framing.	Total.
Sill floor posts	421	3,650	$ 474 50	$ 96 83	$ 571 33

Ties	48	264	34 32	10 08	44 40
Lagging, floors	96	560	28 00	2 80	30 80
Lagging, sides	720	4,197	209 85	20 98	230 83
Drift pins	1,440	457 lbs.	22 85		22 85
Ladders	28	235	4 00	7 00	11 00
Labor standing sill floor timbers					758 16
Totals			$ $3,108 15	$500 34	$4,366 65

Seventy-three thousand tons were taken from this stope. $18,770.52 ÷ 73,000 = $0.257 per ton by former method: $4366.65 ÷ 73,000 = $0.060 per ton by Homestake method; $0.257 — $0.060 = $0.197 saving per ton.

The operation of these stopes has brought out another change in the general working plan of the mine which will make a material saving in the cost of development. Timbered stopes cannot be worked economically more than 80 or 90 feet high, as the timber begins to crush of its own weight, while the untimbered stopes can be carried up 150 feet as well as 100 feet. As a result the distance between new levels will be made 150 feet, which will effect a saving of one-third in development work, and one-third more ore can be recovered from the stopes with the same sill-floor work.

Fig. 19 is a part plan, longitudinal and cross-section of a stope being worked by the Homestake method, and Fig. 20 is a cross-section showing the change as just described.

The Original Source of Platinum.

Among the mysteries that hang over the direct, or remote, origin of certain minerals, that over platinum seems to be gradually resolving itself. We all know platinum, but whence it came until comparatively lately was not known. When we have found it in our placer clean-ups or in Pacific beach sands, it has been as a stranger that has evidently wandered far from home. Even the great nuggets that came from the Ural region in Russia, from which the largest supply of this mysterious metal has hitherto come, bear evideuce in their rounded and battered shape of having traveled considerably from their parent rock and of having been badly used since they left it. The researches of late in regions from which we might have suspected these travelers to have come have been partially rewarded and have found them, at least, in small quantities, at home and in the parent rock.

Platinum, says Spurr, in Vol. XXXIII, Trans. A. I. M. E., in the majority of cases, is fouud closely associated with chromite or nickel, or both.

Like these minerals, it is almost iuvariably genetically connected with basic, olivine rocks, or with the serpentine rocks arising from the alteration of these.

As au original constituent in basic rocks, it is said to have been found by both Daubre and Englehardt.

More recently native platinum has been discovered in the Urals, in Nizhivi-Jagil district and the Goroblagodat district. There it occurs in extremely basic peridotitic rocks containing large amounts of magnetite and chromite, besides platinum.

According to Iuostram Zeff, the platinum occurs as leaves in the chromite. In the Goroblagodat district, while peridotites contain by far the larger amount of platinum, Saytzeff found the metal as an original constituent in other igneous rocks also, such as porphyrite, gabbro-diorite and syenite-gneiss. C. W. Purington also obtained, on crushing and panning the peridotite of this district, many fine colors of platinum. Spurr considers the Ural occurrence in basic igneous rocks and association with the igneous minerals, chromite and magnetite, as a product of magmatic segregation—that is, of a local gathering together in a molten mass of certain elements or constituent minerals of that mass.

So far it seems that platinum has been found only as a constituent mineral—like mica, hornblende or augite—of certain igneous rocks.

At the Rambler mine, a copper property in Wyoming, platinum was discovered by Prof. W. C. Knight of the University of Wyoming associated with other minerals of the platinum group. Platinum ore is also reported from New Zealand.

Small Veins Also Valuable.

That large veins of low-grade ore are uot the only ones that pay to work has often been proven iu Colorado, Arizona, California, Idaho and elsewhere. The large mine, generally speakiug, however, is more popular with investors, as it represents quautity, and the fact is recognized that, given a large quantity of ore, with moderate values and average couditions, a great and euduring industry can be built up, which, under competent management, will prove a profitable enterprise. There are, however, many small mines, those having moderate width of vein, but in which the ore is of such grade as to insure profits as large as those derived from operatious of greater magnitude. The mines of Grass Valley and Nevada City, Cal., are of small or moderate size, yet these mines have proven very profitable for many years. The Eureka-Idaho shoot, near Grass Valley, which produced over $25,000,000, was a vein but 2 or 3 feet in width. The Soulsby miue, at Sonlsbyville, in Tuolumne Co., Cal., has produced over $6,000,000, and is a vein rarely 3 feet wide; the Sheep Ranch mine, in Calaveras Co., Cal., discovered about 1875, has been worked to a depth of 1300 feet, and is credited with a production of over $3,000,000. This vein is never over 4 feet in width, aud is mostly less thau 2 feet. The accompanying illustration is that of the Sheep Ranch mill. In Colorado are veins innumerable, less than 2 feet wide, which have produced millions of dollars at large profit. Small veins, when good, are usually very good, but the management of a mine having a small vein requires as much knowledge as that essential to the operation of a large one, for there are many difficult problems in the development and exploitation of small veins, which are almost unknown in large ore deposits. Among these are the faulting of the vein, the sudden pinching of the ore shoot, the nuexpected influx of large volumes of water, sndden changes in the character of the ore, besides numerous other annoying and sometimes serious problems, requiring an extensive knowledge of engineering, chemistry and metallurgy, beside the faculty of handling men, sometimes under conflicting conditions.

Some Laboratory Work in Cyaniding.

To the Editor:—To those inquiring for a method of determining the oxygen in cyanide solutions, I would refer them to the several methods to be found in Sutton's "Volumetric Analysis," pages 224-225.

Gold-plated zinc shavings, about which there has been some discussiou, are not of uncommon occurrence. I can at present think of more than a dozen places where I have seen and had experience with them, and a cyanide man who shakes his head at such a proposition shows his lack of experience. At Johannesburg, Cal., at the plant of the Johannesburg Reduction Co. (the Red Dog mill), I have seen shavings so completely covered with bright, metallic gold that neither HCl nor H_2SO_4 would touch the zinc, although analysis proved the zinc to be in the greater quantity by more than 50%. HNO_3 seemed to penetrate the film of gold and eat out the zinc, leaving the gold in a very finely divided state—so fine that it actually floated on the solutiou. Again, in Peru, I have seen ziuc shavings so thickly coated with gold that uot even HNO_3 would touch them, the whole mass having a fine, metallic gold color. This pheuomenou looks fine iu the zinc boxes, but is really a sitnation that should be avoided: First, because it renders a large amount of ziuc shavings useless as far as more precipitation is concerned; second, it is hard to recover the gold from such shavings without great expense, for in roasting such shavings the loss by volatilization is great and reduction by dissolving out the zinc is costly, and on account of the film of gold breaking up and floating it is dangerous to handle.

In Peru I finally had to remove such shavings from the head box—in which they always appear—treat them in a rotary zinc shaving washer, such as you described in a recent issue, with a very strong cyauide solution, when the coatiug of gold readily dissolved and left the shavings ready to use again. The strong solution containing the dissolved gold I then diluted to about .12%, ran it through the boxes again and precipitated the same values with the same zinc on which they were precipitated before. Iu seeking the cause for this state of affairs I have made many experiments, and invariably find that it is caused by a rich gold solutiou comiug into contact with the zinc thread when there is not enough free cyanide of potassium present to give the proper reactiou, which is supposed to be $2K\,Au\,Cy_2 + Zn = K_2\,Zn\,Cy_4 + 2Au$. There appeared to be the proper combination of the Au and KCy. It is a well-known fact that an excess of free cyanide must be present to enable the proper precipitation to take place, but in this case we have the wonderful reaction of a filiform precipitation of Au on zinc thread without any free cyanide present. However, on further investigation I always fouud my zinc shavings to coutain an appreciable amount of lead as an impurity, or else my solution to contain mercury in solution, or both. So the cause of this state of seemingly wonderful complications can be directly traced to the presence of some constituents which tend to set up an electric current, thereby electrolytically depositing the filiform gold.

The idea which has beeu suggested, of letting zinc shavings soak in strong cyanide solution over night, is about as big a mistake as anyone could make. Zinc shavings should never be left in cyanide solution that is not running, for in case zinc is left standing

Sheep Ranch Mine, Calaveras Co., Cal.

quietly in KCy solution the precipitation of K_2 Zn Cy_4 immediately begins, and in the morning the zinc thread will all be matted together with zinc potassic cyanide, and every thread of zinc so coated will be unavailable for future use. This is one of the worst combinations that we have to deal with in cyanide practice.

As for using chloride of lime, every well-posted chemist knows that there is more alkali in CaO than there is in Ca Cl_2. Any one using Ca Cl_2 will have to use lots more of it to obtain the same effects, and they are all the time adding chlorine, which has an acid reaction, where it is desired to overcome the acidity in the ores by using a counteracting alkali, such as CaO, or NaOH (caustic soda). His consumption of KCy in using chloride of lime instead of oxide of calcium (lime) will just about be doubled. Such practice is not followed, except for preliminary washes, where certain deleterious salts are to be eradicated, but this, in turn, should be washed out of the pulp under treatment before adding the KCy solutions. It takes a pure alkali to neutralize acid.

JESSE J. MACDONALD.

Los Angeles, Cal., March 7.

Hydraulic Safety Appliance for the Prevention of Overwinding.

Written by R. A. HENRY.*

In this appliance (see accompanying figure) four tubes TT of drawn iron, calibrated to an internal diameter of 3§ inches, are mounted vertically in the upper part of each winding compartment of the shaft. Each tube receives a rod A, traversing a steel stuffing-box and terminating in a piston p in one piece with the rod itself. The upper ends of each pair of rods are bolted to a wooden traverse B. The tubes are fastened to the frame of the compartment by means of rings situated below the stuffing-boxes, and also by eyelets C and iron stays to the pit lining, so that there is no strain on the actual framework when the appliance comes into action. The piston p is provided with a small orifice s, which is gradually covered, in proportion as the piston rises in its cylinder, by a bar, r r, the closing being complete by the time the pistou reaches the upper limit of its stroke. The tubes T are completely filled with a suitable liquid, such as oil, fat, or a solution of glycerine in water. When the roof of the cage passes by the keps G it comes in contact with the traverses, B, the lower surfaces of which are covered with rope fenders to diminish the shock of the impact. By this means the cage lifts the traverses B, and with them the piston rods A and pistons, p, the latter in rising being restrained by the liquid in the cylinders, which liquid, however, is gradually allowed to escape to the under side of the pistons through the orifices s. The resistance in question is sufficient to top the cage, and should the velocity of the cage amount to 50 feet per second the stays are strong enough to cause the winding rope to break.

Hydraulic Safety Apparatus for the Prevention of Overwinding.

Horse Power for 10-Stamp Battery.*

Modern practice in stamp mills includes the use of stamps with weights varying from 500 to 1200 pounds per stamp, and height of drop varying from 4 inches to 10 inches. The diagram herewith shows the horse power required for each 10-stamp battery for weights of stamps and heights of drop between the limits mentioned. This diagram is based upon ninety drops per minute, and includes the friction of the cam shaft in the cam shaft bearing, the friction of the cam against the tappets; the friction of the stem against the guides and the power required for raising the stem vertically. The diagram shows a line for each height of drop from 4 inches to 10 inches inclusive.

To explain the use of this diagram, we give the following example: Required—the horse power to drive a 10-stamp battery of 900-pound stamps, dropping ninety drops per minute, height of drop being 7 inches? Find the figure 900 at the bottom of the diagram under weight of stamps, follow this line vertically until it intersects the 7-inch drop line, then proceed in a horizontal line to the left of the diagram, where it will be found that the required power for each 10-stamp battery is about 17.4 H. P.

Another use of the diagram is in finding the change in horse power by varying the height of drop without changing the weight of the stamp. For example, with a 900-pound stamp, in changing the drop from 7 inches to 8 inches, the increase in horse power for each 10-stamp battery is 17.4 to 19.4 H. P.

The above powers are determined on the assumption that the bearings are properly lubricated and the stems in good alignement.

Diagram for Estimating Power Required in Stamp Mills.

Clarifying Solutions for Colorimetric Copper Determinations.

TO THE EDITOR:—In running copper determinations in Cochise county, Ariz., the writer finds it expedient, because of large zinc percentage, to use the colorimetric method. Wide-mouth bottles, 4 inches high by 1¼ inch in diameter, are used. A standard ammoniacal copper solution, of which 1 c.c. = $\frac{1}{10}$% for 1 gram, is titrated into a blank bottle containing alkalined water (H_2O + NH_4OH). By having the bottles all numbered, a large batch of samples can be run with one blank, beginning with the lowest and passing in succession to the richest solution. Using ½ gram of ore, extremely close results can be obtained up to 15% Cu, and by the simple expedient of dividing the solution into two equal parts, the same accuracy is obtained up to 30% Cu.

The method of solution was simply to use HNO_3 and potassium chlorate. But in many of the solutions appeared a greenish tint, which was very difficult to match with the true blue of the standard solution. No amount of potassium chlorate would remove this. After many experiments, it was found that violent stirring with rubber-tipped rod just before filtering seemed to coagulate this green coloring matter with the iron precipitate, and the beautiful virgin blue of copper hydrate is now invariably obtained.

C. R. TINSLEY.

Mineral Deposits in the Philippines.

In a report on the Mancayan and Suyoc mining districts in the province of Lepanto, A. P. Wright says: The mining possibilities of this section are the best known of any mining zone in the archipelago. It has produced more copper and gold than any other, and that from the surface. It has had a reputation as a mining region for centuries and yet no one knows anything of the ore deposits below a depth of 100 feet. At Mancayan some crude and unsuccessful attempts have been made at legitimate development by the owners of the Mancayan copper mine, but the manner in which the work has been done leaves the field of deep mining virgin. In the mineral zone extending from some 2 miles north to Mancayan to 2½ miles south of the barrio of Suyoc, the ledges are strong, standing up in places more than a hundred feet above the surface.

The Igorrotes, natives of this section, have followed mining as far back as their traditions go, and have mined both gold and copper on this belt for 300 years. No statistics have been kept save from 1840 to 1855. During these fifteen years they, according to the records, exported annually twenty tons of copper pots, pipes and other utensils peculiar to their own make. They have supplied the population of north Luzon with copper vessels, spears and trinkets for years. This product has been taken from the surface croppings of the veins and ledges in these two districts. Their tools and methods of reduction were crude and sustained at all times a loss of at least 20% in smelting. However, these people have developed skill in the working of metals and in the extraction of ores on and near the surface. They are not only copper miners and copper workers, but they are yet more skillful in the prospecting for gold-bearing veins, the extraction of ores and saving the gold. They build reservoirs on the high mountains, and in the rainy season when the water is plentiful they direct the water in ditches from head gates to the gold-bearing veins, and with the pressure they get wash down to the canyons below millions of tons of stone and earth and gold-bearing quartz. The water is turned off, the quartz selected out, taken to their stone mills, crushed and the concentrates separated by washing in a pan made from the bark of a tree. The concentrates are wrapped in a tobacco leaf, placed in a piece of earthen pot surrounded by charcoal, and with fans and blowers all foreign minerals are burned off, leaving a gold button in the bottom. There are no statistics as to the amount of gold that has been taken out in and around Suyoc, but from all traditions it has been considerable.

The Mancayan mine was worked in a desultory way

to some extent by its owners and their lessees, and produced altogether 1100 tons of copper metal. They used the Mexican furnace with charcoal, losing a high percentage of copper, but their books show an extraction of 37% per each ton of ore smelted. This mine is situated on a strong ledge traceable the entire length of the two districts. The ledge has a north and south trend and dips about 70° to the east. The quartz was originally quartz porphyry. Porphyry of a later date than the original porphyry has flowed over and completely capped it. Besides altering the quartz porphyry in its character the dike has been no doubt largely responsible for the ore deposition. The quartzose mass lies on a quartz diorite foot wall and is paralleled on the west at a distance of about 1000 yards with a feldspatic porphyry dike. Copper veins are fouud along both contacts with the diorite.

At Puckdaw hill the belt widens into a large kidney and becomes ore bearing. A central ledge occurs carrying veins of varying thickness containing payable gold with slight copper values. There are many smaller veins paralleling these dikes and all on the east side dip to the west and those on the west dipping to the east, indicating a junction of all at some unknown depth below with the main central vein. The central vein at the surface shows a width of 10 to 20 feet. What is needed is capital, machinery and skill for these two districts to become producers.

While there are many veins that are practically free milling, the ores takeu generally are smeltiug. The copper ores of Mancayan are somewhat refractory, but those of Suyoc contain magnesian lime in abundance in the gangue and very little base metals, and if mixed with the ores of Mancayan a very high per cent of extraction could be had.

There are about 100 claims located in these two districts, and nearly all show ore values aud sufficient indications to encourage developments. The districts are ou the headwaters of the Abra river, water power can be had in abuudance and timber is plentiful. The only drawback at present is inaccessibility. Mancayan is about 55 miles from Candon on the coast, and all supplies and materials have to be brought in over a pack trail.

The climate is healthful and the surrounding country is fertile and the hills and mountains furnish fine grazing for stock.

Cervautes, the capital, 14 miles north of Mancayan, has an elevation of 1700 feet above sea level, Mancayan 3983, Tubuc 4540 and Suyoc 5518. With these elevations white men can work the year around, as well as in the States.

The Comstock Lode and Its Future.

The Comstock Lode at Virginia City, Nev., has ever since its discovery in 1859 to the present day been one of the most interesting mineral deposits known to the miuing world, and it will continue to be of interest for years to come. In a little volume to be circulated at the Exposition at St. Louis, Mo., the following appears, written by G. McM. Ross, who is well qualified to describe the workings and metallurgical methods of the great Lode, having grown up with the industry. After an interesting historical sketch, the writer says:

The rich gold and silver ores were shipped to and sold in San Francisco, while experiments were being tried on the Comstock and in San Francisco on all sorts of processes and devices for the recovery of the values in gold and silver contained in the Comstock ores. The miniug companies themselves undertook the reduction of their ores with an equipment whose magnificence was only equaled by its inefficieucy. To this first work can be credited the imperfect and costly treatment of the Comstock ores that has lasted until the preseut day. Shrewd, hard-headed, practical men built mills for the reduction of Comstock ores, and, as a result of their joint efforts, the Washoe process was evolved. When this process had been established as the one best adapted for the reduction of the ores, the profits derived from milling were so large that powerful milliug companies were formed, and any efforts at the milling of their own ores by the mining companies were effectually discouraged.

The Washoe Process.—The Washoe process is the Americanized Mexicau patio process and is used for the extraction of gold and silver ores in the following way: The ore is crushed in wet-crushing 5-stamp mortars to a fineness ranging from twenty to forty mesh; the crushed ore is settled in square tanks, set ou the pan-floor levels; the finest of the slimes is settled in reservoirs outside of the mill. The crushed ore, when settled, is charged into fast-running grinding pans holding a charge rauging from one to two tons; the pans are either steam-jacketed or arranged to take live steam into the charge; the ore is kept at such a consistency as, with the motiou in the pans, will keep the quicksilver, which is added to each charge of ore, in suspension in the charge. Chemicals are used in the process, usually bluestone and salt, and the ore worked hot. The treatment lasts from three to six hours in the pans that are finally discharged into settlers (a slower-motion pan to which large quantities of water are added) to insure the settling of the quicksilver with its charge of gold and silver in such a way that the pulp or ground ore will not settle; the pulp is slowly discharged from the settlers, the quicksilver recovered and strained to secure the gold and silver amalgam, which is usually ground in a clean-up pan to remove impurities, restrained and retorted; the resulting crude bullion is melted into bars of nearly fine gold and silver.

The mill arrangement and equipment is as follows: For ten stamps of 900 to 1000 pounds each four standard 2-ton pans are required, with two settlers and a slow-motion clean-up pan, retort, assay office, etc. The actual horse power required will be sixty; but, to provide for extra rock-breaking service, a modification of the process, etc., it will be well to provide 75 H. P. for the work. Such a mill will treat from thirty to forty tons of ore per day at a cost ranging from $3 to $7 per ton, depending upon the loss of quicksilver, cost of water, power, etc. In the treatment of the ore such a mill will use 50,000 gallons of water per twenty-four hours; about 50% can be settled and used over again when water is scarce aud expeusive. The following modifications of the Washoe process have been introduced: Plate and battery amalgamation is being used successfully. The free gold contained in the gold and silver ores is amalgamated and recovered from the mortars upon silvered copper plates that are used before the ore reaches the settling tanks; the ore is, after passing over these plates, treated in the same way by the Washoe process as the ores first referred to.

Concentration Before Amalgamation.—In ores containing heavy sulphides it has been found that, by removing these sulphides before treating the ore in amalgamating pans, a higher percentage of the values is recovered at a reduced cost. Any type or kind of concentrator that will remove the sulphides can be used for the work.

The Comstock's Product.—With this process established, the production of gold and silver bullion from Comstock ores was rapidly increased. In 1860 the yield was: Gold, $550,000; silver, $200,000. In 1861: Gold, $2,500,000; silver, $1,000,000. By 1864 the productiou had reached: Gold, $6,400,000; silver, $9,600,000. By 1869 the output of gold and silver had dropped to $7,405,578. From 1870 to 1877 there was a steady and rapidly iucreased product—in the last-named year, that of the greatest output, $14,520,614.08 being gold aud $21,780,922.02 beiug silver. The total output of the Comstock mines in gold and silver to the end of 1902 is probably very close to $371,000,000. Of this sum there was about 60% silver, the remaining 40% being gold. These values were recovered; the losses are estimated at between $60,000,000 and $80,000,000; of this loss modern methods would have saved 70%.

The Mining of Comstock Ore.—The discovery of the silver sulphides having been made by placer miners, it was some time before the nature of the lode was understood. The first ore was found in small westerly dipping veins that, on being followed, developed into great masses of ore that turned when nearing the easterly dipping foot wall, and the vein or fissure followed this wall to a depth of 3200 feet below the surface. In a short time after the discovery of the silver sulphides, the mining world was fairly represented on the Comstock by men interested in some phase of mining. Added to them were the speculators and gamblers. The result of their combined efforts was to cover the surface of the earth with hundreds of mining locations, as the speculators and gamblers soon discovered that mining claims had a speculative value. On the Comstock the main lode was soon outlined and reduced to ownership by many companies. Of these twenty-eight have maintained their orgauizations to the present time. The ore bodies of the main lode were so much larger and richer than anything fouud in the outlying mines that attention and work soon concentrated upon the mines of the main lode, notwithstanding the fact that to the east and west of the Comstock Lode ore of value was found in quantity which, under conditions less excitiug than were brought about by the development of the main lode, would have been successfully worked, as it surely will be in the not distant future.

The high wages that were paid to the miners aud mechanics on the Comstock was the magnet that attracted the most skillful of these men from the euds of the earth. The managers were thus enabled to meet the unusual difficulties of mining large bodies of ore, handling large quantities of water and opening up new ground where the temperature was unusually high. The quartz miners of the Comstock had penetrated the lode to a depth of 3000 feet within twenty years of the discovery of silver sulphides on the surface. Within that time the simple hand windlass had been superseded by more and more powerful machinery, until direct-acting hoisting engines of 1000 H. P. were being used. These engines were designed for work to a depth of a mile below the surface. A tunnel was started and connected with the lode from a point in the valley of the Carson river 4 miles distant, thus forming a new base of operations 1600 feet below the surface. Powerful pumping machinery was installed at various points along the lode, one such installation costing $1,000,000. After a spleudid dash at attaining great depth, aud but a partial development of these depths, that failed to bring forth a Bonanza, while being threatened on every side by known bodies of hot water, a retreat was ordered and 1700 feet of opened and partly developed depths were abandoned and the hands upon the Comstock's dial were rudely thrust back for at least a quarter of a century. The reason and excuse for this was the fact that no unity of interest had ever been acknowledged by those in control of the various mines or groups of mines on the Comstock, and even science failed to give a reasonably definite statement of what might be expected of the Comstock in depth.

A pump had been iustalled and operated under conditions that at that time had never before been encountered by an eugineer; yet the pump was so perfect and efficient that, had a united effort been made by the principal mines of the Comstock, this pump could have been operated and the lower levels need never have been abandoned.

A vertical depth of 3300 feet was reached before the lower levels were abandoned. It was several years before the water again rose to the level of the drain tunnel, 1700 feet above. During these years millions of dollars were extracted from ore bodies that formed the margins of the old Bonanzas on the Comstock. It is one of the remarkable features of these ore bodies that they begin and end in quartz bodies—quartz being the gangue or matrix in which the ore is found, the ore forming a rough central core or lens surrounded by quartz, carrying but little ore. In Bonanza days, and during the mad rush to extract a great number of tons per day, the heart of the Bonanza was literally torn out of its quartz body, and in every instance where a Bonanza was found and mined it has paid to mine the ground again. It is also true that, in several instances, a greater tonnage was extracted during the secoud period of miuing than during the first, even when it was not possible to mine the ground thoroughly.

By 1898 the couditious on the Comstock were cheerless and nearly hopeless. Mauy of the mines were practically abandoned; ruin and decay were the prominent features. At this period, a few men, to whom failure and defeat were unknowu terms, with tireless energy and boundless faith in the Comstock, worked at, and succeeded in getting together, the loose ends of the many iuterests that centered iu the Comstock and in conviucing those in control of those interests that to save the Comstock from complete abandonment a united effort must be made to recover the lower levels of the Lode. These men were so far successful that a provisional and temporary union of all Comstock iuterests was formed by twenty-eight mines enteriug into and forming the Comstock Pumping Association. The operations of this association were successful. The original plan succeeded iu recovering 400 feet in depth of the flooded levels, in the discovery of au ore body, and in the re-establishment of sufficieut confidence iu the Comstock miues to warrant a geueral resumptiou of work aloug the Lode.

The device used in draiuing the Lode is a modified hydraulic elevator desigued to use water under a head of 2000 feet and over. Using water under such great pressure brought forward problems iu hydraulics that are not yet solved. The advantages of the system are so great as to economy of space and first cost that every feature of the system deserves the most careful study, with the view of attaining final perfection and highest possible efficiency. Before $100,000 had been expended in this system, more water was discharged into the drain tunnel at one time by it than had been discharged by the $5,000,000 worth of pumps formerly iu operation on the Comstock Lode. Shortly after this system had been in fairly successful operation it was decided to operate the mines of the Comstock by electric power. A company was formed that secured coutracts for power paid in advance of delivery aud the power plant was built. The plant is now in successful operation, deliveriug power that is used in mining, pumping, milling ore, aud for lighting, from a generating statiou at a point ou the Truckee river 33 miles distant from the Comstock Lode.

The Future of the Comstock.—This statement is not intended to be prophetic. The author has knowledge of Comstock history, and of the strange freaks it has produced iu the lives of men and in the condition of things. In these actions and reactions, Bonanzas and Borraseas have played almost equal parts. The Bonanzas have deluged men with more money than they could count; the Borrascas have wafted our men and women to other scenes where fame and fortune became theirs.

The most striking fact in the history of the Comstock is revealed by a study of the working maps. While it is true that a vertical depth of 3300 feet has been reached on a vein with an average dip of 45° to the east, and that hundreds of miles of tunnels and drifts have been run, it is equally true that barely 20% of the lode above the 1600-foot level has been prospected, that to-day good ore is being extracted withiu a few feet of the surface at many points, and that millions of tons of ore will yet be profitably worked from the croppings of the lode. Below the 1600-foot level 7% would be a very liberal allowance for the prospected or developed ground of the Comstock Lode.

The second fact is that no modern complete milling

plant for the reduction of ores exists on the Comstock. It is true that first-class modern work has been done, and that ores are now being reduced at a fraction of former costs, but the credit for this work is due to individual effort, and not to the direct action of any mining company. The data now available is conclusive as to what percentages of the values of Comstock ores can be recovered. The unaltered ores, treated by plate amalgamation and concentration, yield from 60% to 80% at once. Of the remaining 20% to 40% of the value, there can be recovered 60% to 70% by cyanide treatment. Of the other Comstock ores nearly equal results can be obtained and at not greater cost. Our neighbors in California and to the east are treating ores in this way, crushing, amalgamating, concentrating and cyaniding the tailings in quantity for $1 per ton of ore treated.

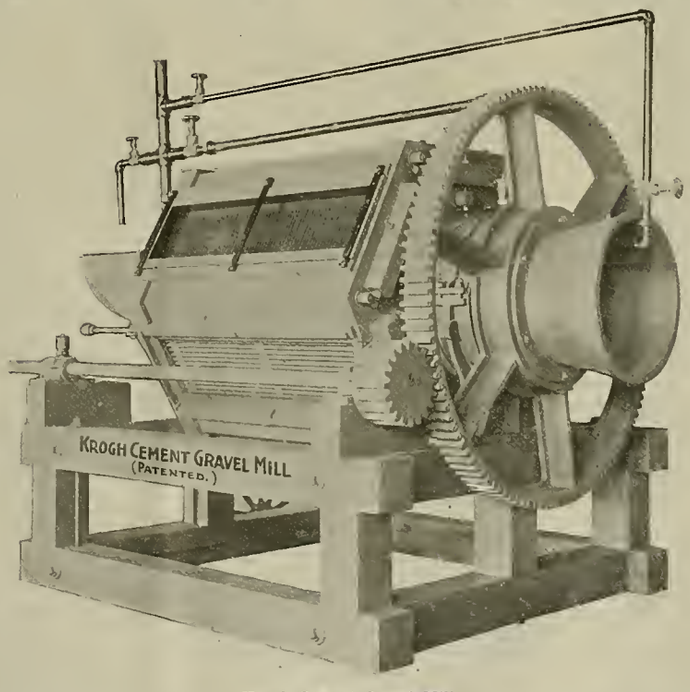
From these facts, it is reasonable to assume that the law governing the occurrence and recurrence of ore bodies will be discovered and the discovery published for the benefit of mankind. The low costs of mining and milling, so general throughout the world, will at least be duplicated on the Comstock. Those in control of the mines will become students of the great Lode.

Those who have the best information of the Comstock Lode can safely say that there is no mining field known in the world that offers inducements so great and lasting to the student, the capitalist, the mining engineer, or the speculator. If the man exists who combines in himself the best of these qualities, the Comstock is the field provided by nature for the full development of every faculty with which he has been endowed.

The Krogh Gravel Mill.

From Mariposa to Siskiyou county, Cal., and extending into Oregon, there are extensive bodies of gravel which in their deep-seated or unoxidized portions are known to miners as "blue leads." Many of these ancient river beds or channels contain gold in quantities that pay good profits to work. These bodies of gravel are frequently more or less cemented. So firmly cemented are these gravels that the largest hydraulic giants under the heaviest pressure are unable to disintegrate them and separate the gold. Masses of cemented gravel will travel for miles in sluiceways without breaking up fine enough to release the gold. Gravel coutaining low values can be mined and worked at a profit if some comparatively inexpeusive method is had for disintegrating the cemeut. These cemented gravels frequently carry high values in gold.

The accompanying cut illustrates a mill which is built to handle cemented gravels, and according to the manufacturers meets the requiremeuts of working at low cost with high efficiency and large capacity. Several have been built and are in use, demonstrating their adaptability and success. A process of separation and not of crushing is employed, as a large per cent of the wash (the boulders constituting fully 60%) is dead material.

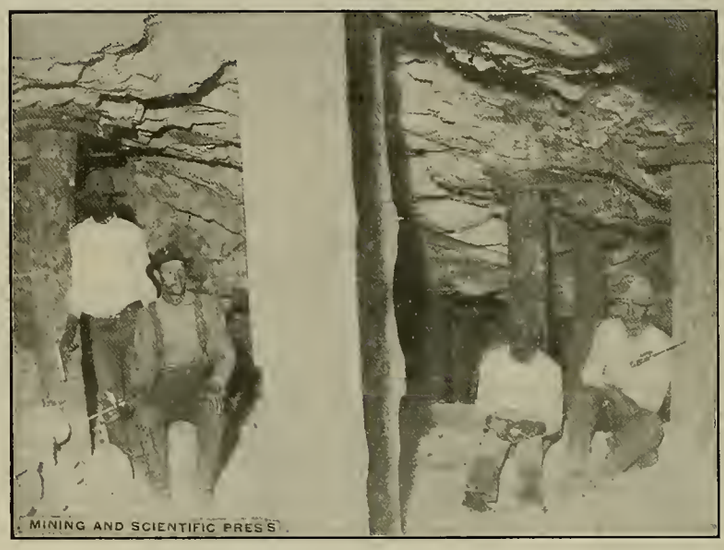


Krogh Cement Gravel Mill.

The Krogh gravel mill is designed to handle this material and to operate on the principle of disintegration, the boulders being employed to work against themselves, and by contact wear away and reduce to pulp the finer particles of gravel which adhere to them. The mill may be described as a revolving hexagonal barrel. By reference to the accompanying illustration it will be noted that the six sides consist of parallel bars or grizzlies, through which the material drops when reduced sufficiently fine, when it comes in contact with a screen, and if then fine enough drops through onto an amalgamating table. If not of the right consistency to pass the screen, it is returned to the revolving mass of material and ground still finer. The mill is about 6 feet long and 4 feet wide, with feed entrance at one end, and discharge for waste material at the other, the fine gold-bearing material passing out at the sides. The manufacturers say it has been shown under working test that one of these mills, weighing but thirteen tons, will readily disintegrate ten tons of cement gravel per hour, requiring 10 H. P. and revolving fourteen to twenty-four turns per minute. Further particulars regarding this mill can be obtained from the Krogh Manufacturing Co., 519 Market street, San Francisco, Cal.

Posts and Breasting Caps.

In miuing in veins or beds some system of timbering is usually necessary, though in some dry regions large areas are stoped without the aid of timber supports. In limestone this is often, though not always, the case. Square sets are elaborate and expensive, and there are often instances where the more simple method of posts and breasting caps, or posts aloue, may be safely employed to support a roof. The accompanying engraving illustrates a stope in a Cananea miue in Mexico, where the roof is firm enough to admit of this kind of timbering. In this instance a piece of 2-iuch plank is placed above the post and a number of wedges driven in to make it firm. By carrying a line of these posts and caps sufficiently close to the face extensive stopes may be cut on flat veins. This method of timbering is commonly employed iu drift gravel mines and in many coal mines. Often a great many of these "props" may be recovered when retreating from worked-out portions of the mine, the roof falling as the support is withdrawn. Whether it is economy or not to remove any particular post is a matter of judgment which the foreman or superintendent must decide. Often the labor expended in the removal of a post is worth more than the post itself when it has beeu recovered. This practice is much more common iu coal than iu metal mines.



Stope in a Cananea Mine, Mexico.

Mechanical vs. Hand Stoking.

A comparative test of hand stoking against mechanical feeding of pulverized coal dust, using the C. O. Bartlett & Snow system of burning pulverized coal, was made on Feb. 2, 1904, at the McCormick Division of the International Harvester Co., Chicago, Ill. The test was carried on under two B. & W. boilers, rated at 120 H. P. each, with a total heating surface on each boiler of 1200 square feet, the ratio of heating surface to grate surface being 44.4 to 1. The C. O. Bartlett & Snow Co. give the results of the test as follows: In hand stoking, 9400 pounds of fuel, Illinois coal screenings (10.5% moisture), were employed, and in the mechanical feeder 9713 pounds coal dust (40-screen) were used, containing 3.5% moisture. The screenings produced 1934 pounds of ash and refuse, the dust none at all, beside making practically no smoke. In the mechanically fed boiler 66,255 pounds of water were fed and in the other 43,193. Total water evaporated in the mechanically fed boiler, 64,940 pounds; in the haud-stoked, 42,329 pounds. With the former 253.9 H. P. were developed, being 55.5% efficiency, and with the latter 165.5 H. P., which is estimated at 41.53% B. T. U. The relative cost of the two methods is shown as follows:

COST OF EVAPORATION, $1.72 COAL PER TON.

Cost fuel per 2000 pounds of pulverized coal delivered in boiler room.....$2.10
Cost required to evaporate 1000 pounds of water from and at 212° F. (exclusive of firing, repairs, depreciation, etc.)..... 0.1455

$$\frac{12{,}555}{965.8} = 13$$ pounds water evaporated (if total heat units were used) per pound coal as fired.

$$\frac{7.214}{13} = 55.5\%$$ efficiency.

COST OF EVAPORATION BURNING SCREENED COAL.

Cost fuel per 2000 pounds of screened coal delivered in boiler room.....$1.72
Cost required to evaporate 1000 pounds of water from and at 212° F. (exclusive of firing, repairs, depreciation, etc.)..... 0.1770

$$\frac{11{,}300}{965.8} = 11.7$$ pounds water evaporated (if all heat units were used) per pound of coal fired.

$$\frac{4.859}{11.7} = 41.53\%$$ off.

The Deepest Shaft.

The Red Jacket shaft of the Calumet & Hecla copper mine, iu northern Michigan, is the deepest in the world. It has taken nine years of day and night work to sink and has cost $2,500,000, says Industries and Iron. This shaft is vertical, but all of the other shafts of the Calumet & Hecla follow the dip of the lode. Work ou it was started in 1889, immediately after the last of the three great underground fires in the older workings of the mine, which did damage of more thau $1,000,000. Work has been continued upon it since that time, and the shaft stands without a parallel in mining. It is 4920 feet iu depth, or 360 feet less than a mile. It contains six compartmeuts, each equal in size to an ordinary mining shaft, four of which are used for hoisting rock and lowering timber. One shaft is utilized for the ladderways, and the sixth compartment carries the wires and pipes for telephones, light, power, water and compressed air.

Mount Morgan Official Report.

The semi-annual report of the Mount Morgan gold mine of Queensland, Australia, contains much that is of interest to mining men everywhere. The property is one of the largest in the world, and it has had an interesting career since its discovery. The following is an abstract of Manager H. P. Seale's report for the half year ending November 30, 1903:

Open Cut.—Following are the quantities of stone excavated from the open cut workings during the half year: Pay stone, 62,349 tons; waste material sorted from pay stone, 74,185 tons; overburden removed by contract, 47,578 tons, overburden removed by steam shovel, 48,175 tons; total, 232,287 tons.

All the pay stone was "oxidized" and was sent to the West works for treatment.

The system of breaking down the stone onto benches and hand shoveling it thence into trucks is being superseded, wherever possible, by the milling system, by which the stone is broken directly around the shoots, which gradually assume the shape of inverted cones, and the contents drawn as required from the working tunnels and drifts below. New drifts and raises are being cut and all drifts will carry electric traction, for which the present plant is sufficient.

The removal of the overburden on the eastern side of the mountain has been pushed on as fast as possible, the quantity removed by contract and the steam shovel amounting to 96,253 tons for the half year. The steam shovel was started the first week in September, and has, consequently, been running three months. The amounts excavated each month have been 7000, 14,595 and 26,580 tons, respectively. This last tonnage—equal to, roughly, 1000 tons a day—is about its full capacity on the present bench. It can be considered particularly satisfactory, as the plant is working under difficult conditions, on the side of a mountain which affords few facilities for handling such a plant, and in country rock, all of which has to be blasted down. The plant will be lowered to the 252-foot bench, 56 feet below the present working bench, early in January, where better conditions should prevail, although a good deal of delay is anticipated from having to move the plant about as pay ore is uncovered.

Underground Workings.—Following are the quantities of pay stone, sulphide ore and waste material mined below. All the pay stoue was "mundic" and was sent to the Mundic works for treatment: Pay stone, 59,970 tons; sulphide ore, 301 tons; waste material (worthless stone and dike), 5901 tons; total, 66,172 tons.

The development work included: Drifting, 754 feet; sinking, 531 feet; diamond drilling, 3770 feet.

Much development work will have to be done in the future. This applies to all levels. Bodies of ore have been simply encountered and stoping started without in any way blocking out the stone first. The large faces presented by the stopes indicate immense bodies of stone still ahead, but any estimate of these would be speculative until systematic development has been done. This will be effected by diamond drilling at fairly close intervals, so that no stone will be overlooked, and going much farther afield than heretofore.

The prediction in last year's report of finding copper-bearing ore on the 750-foot level, in sufficient quantities for profitable treatment, has been realized. Diamond drilling on this level has shown 62,000 tons of ore, averaging 8 pennyweights of gold per ton and 3½% of copper for every 10 feet of depth. All the drilling was horizontal, except for one vertical up and one vertical down bore on the eastern edge of the deposit. The up bore showed 75 feet of ore of the above grade, when a flat dike was met with, after which values fell a little, and the bore had to be stopped. The down bore interseeted an entanglement of dike and pay ore, after 54 feet of which values again sunk. These bores are two of a series of bores that are being put down vertically, and, considering the present development horizontally and the structural features of the deposit, a good showing vertically can be reasonably looked for.

The cost of mining per ton of pay ore is on the increase with depth, as the ground is more difficult to break on the lower levels and the proportion of waste is naturally increasing with the fall in grade. But the fact that the stone is harder and makes better standing ground offers the compensating feature that important departures can be made from the present square set system of timbering in the lower levels, and a modified filling system, with very little timbering, can be adopted. Spaces will be left around the filling where stone is showing, so that no stone will be buried up that might later on permit of profitable treatment.

The recent discoveries on the lower levels call for a modification of the proposed new hoisting arrangements, and the new shaft will not be located until more diamond drilling determines the best position and inclination.

Reduction Works Report.—The total amount of ore received was 123,485 tons; 62,349 tons, being oxidized ore, was treated at the West works, and 61,136 tons, being sulphide ore, was treated at the Mundic works. The amount treated at the latter works was a little less than the recent average, and that at the West works about 1000 tons more per month.

The costs of treatment have been reduced, as shown by the comparative statement, each operation showing a reduction:

MUNDIC WORKS.

	Cost per Ton, 12 Months Ending May 31, 1903.	Cost per Ton, 6 Months Ending Nov. 30, 1903.	Decrease in Cost per Ton.
	s. d.	s. d.	s. d.
Crushing	2 4 87	2 3.07	0 1.80
Roasting	5 11.20	5 3.98	0 7.22
Chlorinating	4 8.93	4 0.72	0 8.21
General work	1 10.13	1 6.73	0 3.40
Totals	14 11.13	13 2.50	1 8.63

WEST WORKS.

	Cost per Ton, 12 Months Ending May 31, 1903.	Cost per Ton, 6 Months Ending Nov. 30, 1903.	Decrease in Cost per Ton.
	s. d.	s. d.	s. d.
Crushing	2 7.99	2 5 87	0 2.12
Roasting	3 1.06	2 9.13	0 3 98
Chlorinating	4 1 21	3 1 40	0 11 81
General work	1 7 01	1 2 78	0 4 86
Totals	11 5 90	9 7 18	1 10.72

These results are due to a great number of detailed improvements and economies, rather than to any radical alterations in connection with either works.

The usual amount of repairs have been effected during the period under review.

The only additions of note made to the works consist of 240 yards of canals for the precipitation of copper from the Mundic works liquors, and a trial gas producer for firing one of the West works furnaces. The latter has answered its purpose and has shown that important economy can be effected by firing all furnaces similarly. Sets of these will be added to both works.

A considerable number of minor alterations are contemplated for the purpose of reducing cost of treatment, and the more important have been gone into sufficiently to render their success assured.

Tailings.—In addition to the ore treated from the mine, 13,914 tons of tailings were retreated at the Lower reduction works and 1549.64 ounces of fine gold obtained.

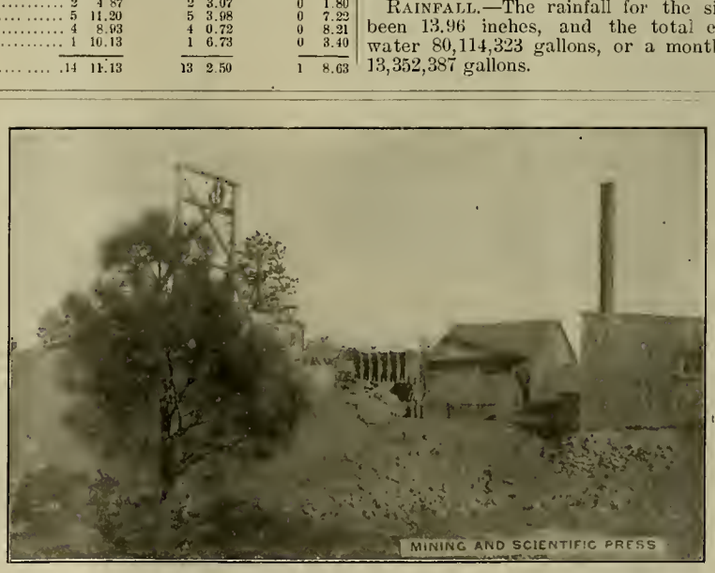
The following table will show the quantity treated at each works and the gold obtained:

Works.	Tonnage.	Bullion Obtained.	Value.	Equal in Ounces of Fine Gold.
Mundic	60,290	27,055.39	3 18 7 44	25,360.09
West	63,527	28,220 71	3 17 8.32	25,572.36
Lower	13,914	1,727.70	3 17 11.38	1,549.64
Totals	137,731	57,003.80	3 18 1.68	52,472.09

The average yield per ton of ore at the respective works is as follows:

Works.	Tonnage.	Value per Ton of Ore. Dwts.	Shillings.
Mundic	60,290	8.41	35.731
West	63,527	8.05	34.194
Lower	1,394	2.22	9.455

Rainfall.—The rainfall for the six months has been 13.96 inches, and the total consumption of water 80,114,323 gallons, or a monthly average of 13,352,387 gallons.



Ideal Mine, Groom Creek, Yavapai Co., Ariz.

Pine Mountain Mill, Lynx Creek, Ariz.

Hoist Monte Cristo Mine, Groom Creek, Ariz.

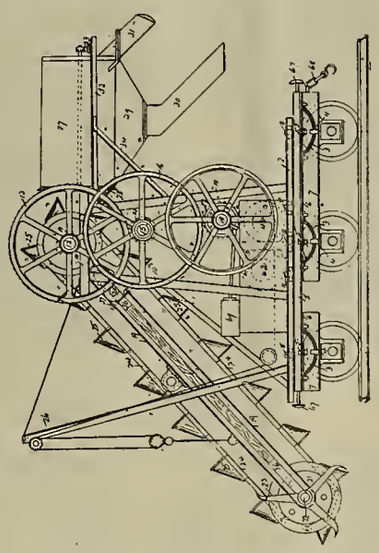
(See Front Page.)

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 1, 1904.

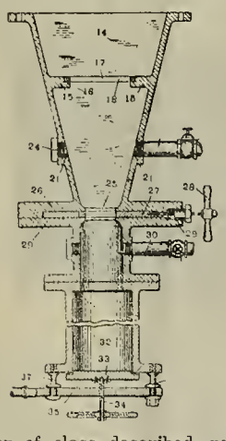
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MACHINE FOR EXCAVATING, RAISING, SCREENING AND FILLING GRAVEL BALLAST, ETC.—No. 752,709; H. Quertier, Dunedin, New Zealand.



In machine for excavating and raising gravel ballast and like, in combination, traveling truck, base plate thereon rotating about king bolt, tumbler frame upon base plate, bucket ladder carrying buckets moving upon frame, means for driving same and also winch drums, headline that is wound upon one of drums and bowlines upon other drums, outer ends of lines being attached to anchors suitably situated so that when either of bowliues is inwound base plate and superstructure may be swung round complete circle if need be.

SEPARATING HOPPER FOR STAMP MILL LAUNDERS.—No. 752,702; F. W. O'Neil, Painesdale, Mich.



In separator of class described, receiviug basin having orifice through its bottom, hollow leg mounted beneath basin, means for closing leg, valve for closing communication between leg and basin, and water supply pipe between basin and valve.

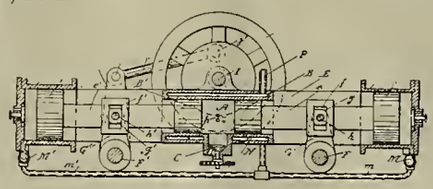
TAPPET FOR THE SHAFTS OF ORE STAMP MILLS, ETC.—No. 752,907; P. C. Kelly, Sandycroft, England.

Tappet formed of two sections, larger having longitudinal gap at least eqnal to diameter of shaft to which it is to be secured aud smaller section forming gate being of size to fit gap and having surface shaped to fit shaft and means carried by gate section for forcing and holding it directly agaiust shaft.

METHOD OF EXTRACTING GOLD FROM REBELLIOUS ORES.—No. 753,822; E. C. Broadwell, Chicago, Ill.

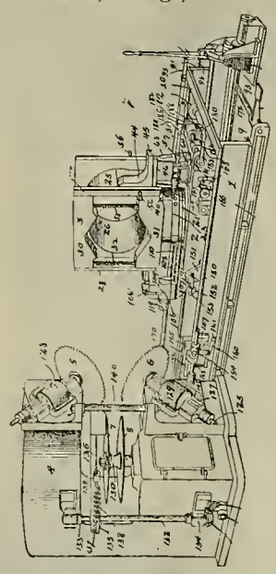
Method of extracting gold or platinum from rebellious ores, comprising first pulverizing ore, next mixing same with alkaline or alkaline earth hydrochlorite solntion to which proper molecular qnantities of oxysalt of heavy metal which can be precipitated by hydrogeu sulphide from its acid solutions has been added.

AIR COMPRESSOR.—No. 753,787; C. S. Dean, Buffalo, N. Y.



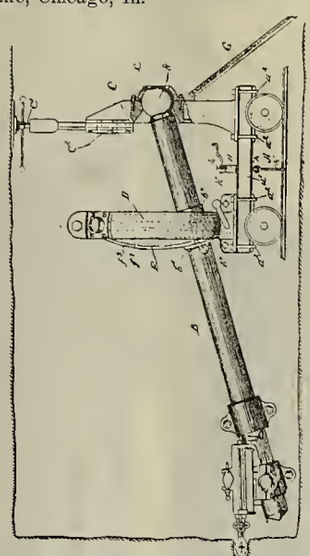
Combination, with power cylinder, and two compressor cylinders arranged at its ends, of pistons slidable in cylinders, pistou rods conuecting pistons together in pairs and having guide slots at middle parts between pistons, guide blocks slidable vertically in slots, crank shaft, pivoted arms operatively connected with guide blocks, and driving connections between arms and crank shaft.

MACHINE FOR SAWING MINING TIMBERS.—No. 753,688; D. W. Edwards, Chicago, Ill.



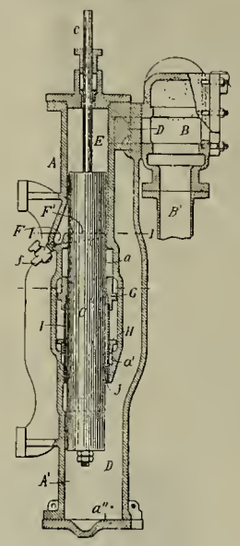
In timber dressing machine, combination of main frame, chuck adapted to grip timber intermediate its length, mounted to reciprocate upon main frame, means for rotating chuck about axis concentric with longitudinal axis of timber gripped thereby, means for swiveling chuck upon axis perpendicular to first mentioued axis of rotation, iudependently operatmg antomatic stop mechanism for arresting rotation of chuck at predetermined points of rotation abont each of axes, and rotary cutting tools mounted adjacent to path of timber carried by chuck.

MACHINE FOR EXCAVATING ROCK.—No. 753,477; C. T. Drake, Chicago, Ill.



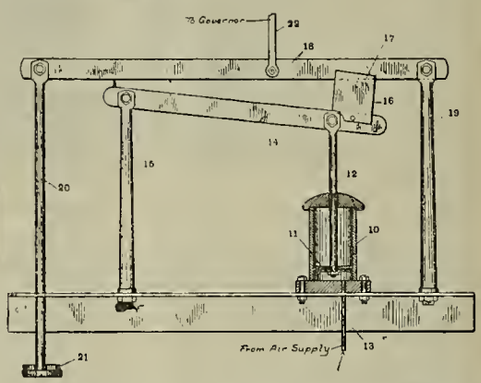
In machine of class described, combination with support of colnmn bar pivoted thereon, means located between snpport and free end of column bar for concentrically adjusting position of column bar with respect to given center and means for rigidly securing same in adjusted position.

VERTICAL PLUNGER SINKING PUMP.—No. 753,550; E. M. Coryell, Monnt Vernon, N. Y.



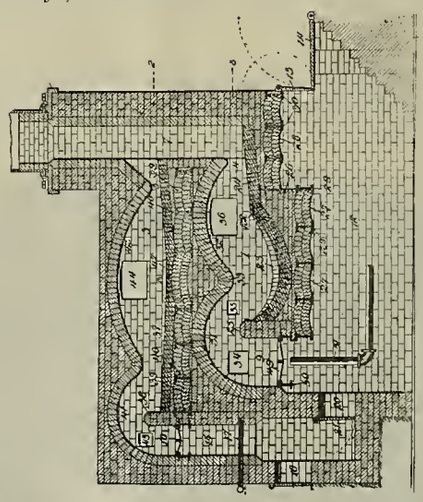
In pump, combination with two-part working barrel contaiuing two water chambers, and double-action plunger extending into both chambers, of conuection for barrel comprising packing adjacent to plunger and closing bottom of upper chamber, second packing that closes top of lower chamber, and tube interposed between plunger aud second packing, whereby plunger encounters friction from one packing only while ready access may be obtained to parts from side.

GOVERNOR FOR AIR COMPRESSORS.—No. 753,633; H. Saam, Mohawk, Mich.



In air governor for air compressors, combination with cylinder communicating with air supply and piston therein, of lever, connection between lever and motor governor, second lever connected to piston, and cam block forming connection between two levers whereby as piston shifts ratio of leverage will change.

METALLURGICAL FURNACE.—No. 753,712; F. Kepp, Brooklyn, N. Y.



Metallnrgical furnace iucluding discharge flue, melting chamber and superposed initial heating chamber, chambers having indepeudent communication with discharge flue at rear ends, separate heating means arranged to direct products of combnstion through chambers to flue, and means for establishing communication between chambers at points intermediate of ends.

Mining Summary.

Specially Compiled and Reported for the Mining and Scientific Press.

ALASKA.

A. N. Nadeau, foreman of the Jualin mine at Berners bay, near Juneau, says the work of the Jualin has progressed satisfactorily this winter, and everything is ready to start the mill as soon as there is water enough. The winter has been mild, with little snow, and mining operations have not been hindered as in former years.

Nome reports say a second paystreak has been found on Dexter creek, which was previously known as one of the rich streams on Seward peninsula. The discovery was made on the Sugar claim, owned by the Pioneer M. Co., which has employed drills to investigate character of its auriferous ground to a depth below that reached by usual placer mining methods. Work was started on a shaft, which, on January 1st, had been sunk 160 feet. Work has been started on its extension, 70 feet farther, to a second level. This shaft required 20,000 feet of lumber.

ARIZONA.

Cochise County.

The February product of the Calumet & Arizona mine, near Bisbee, was 1250 tons of blister copper.

Graham County.

The Arizona C. Co. at Clifton is arranging to equip the Humboldt, one of their best developed and largest producing properties, with electric haulage and electric lights, says the Copper Era. The power will be supplied from the Longfellow concentrating plant and cabled to the mine at Morenci, a distance of 1 mile. A 30 H. P. electric locomotive will be used for hauling the cars, which will have capacity of six tons each, handling thirty-six tons to the trip. There will be 2 miles of track in the mines equipped for electric haulage, and the mines will also be lighted with incandescent lamps. The lower levels will not be equipped for electric haulage as yet, as the bulk of the ore is now coming from the upper levels. The mine is producing 800 tons of ore per day, which requires eight mules and sixteen men to bring it to the surface and dump it into the ore bins. With electric haulage the ore will be handled in one shift. A tunnel has been driven through Copper mountain on the Humboldt workings, after which the track crosses the gulch and connects with a tunnel on the Clay mine, which has been driven in several hundred feet. A plant for air drills is being put in at the face of the Clay tunnel, which will be used in driving this tunnel through the mountain, when it will come out on the other side at head of Queen incline. When this tuunel is completed ores from Queen mine will be sent out over the trolly line and through those tunnels to mouth of Humboldt tunnel at Morenci, and conveyed from there to the Longfellow concentrator by railroad. The tunnel through the Clay mine will also be used for operating the Carasco and other mines on the same mountain. Arrangements are being made in the gulch between the two tunnels to desulphurize the heavy sulphide ores which are coming from the Carasco mine. A hoisting plant is being built on the Humboldt for operating its lower levels, which have reached depth of 450 feet from mouth of tunnel. Work is progressing on a system of dams for storing the tailings from the Arizona C. Co. concentrator, which will be in operation this month. The tailings will be dried, then hauled by cars back to the mines and used for filling the old workings. This will do away with annoyance of tailings in Chase creek. A new hoisting rig is also being arranged for the Yavapai. The work of opening up the new Longfellow at greater depth is progressing, new levels having been run lower down the mountain, which are being connected with workings above. Another tunnel is also being driven in from Chase creek, which in time will be connected with the Longfellow workings, affording new outlet for the ores, doing away with the hoisting plant and also opening the mine at greater depth. Arrangements are being made in all departments to handle an increased tonnage, and at less expense.

Maricopa County.

(Special Correspondence).—J. Anderson and H. H. Gillespie of Wickenburg, owning mining property in the McDowell mountains, have begun development work. F. E. Withey of the Grand Traverse & Arizona M. Co., operating in the Cave Creek district, says the company expects to build a smelter this spring. Development work is progressing on two claims of the group 8 miles northeast of Cave Creek postoffice. A. W. Bennett of Glendale, of the Illinois C. Co., operating west of Wickenburg, reports continued improvement in the ore in the shaft, which is down 70 feet.

Wickenburg, March 5.

(Special Correspondence).—The A. E. Cobb mines have been sold to N. A. Sanders and W. E. Williams of Phœnix.—Manager Swikerath of Phœnix, of the Calamity M. Co., operating on Camp creek, reports work progressing. The ore carries gold, silver and copper. A body of high-grade ore has been opened up.—J. Lamboye and S. Gradio are developing a copper property in Vulture district, 7 miles west of Morristown.

Preparations are being made to work the Union mine, north of Phœnix. An abundance of water has been developed near the mine.—D. Cleberat has sold the tailings at Smith's mill to parties who will cyanide them.

The White Tanks M. Co. has several carloads of high-grade copper ore at Beardsley awaiting shipment to its smelter at Wickenburg. At the smelter they are making alterations and improvements.

There is considerable activity in mining in Buckeye section.—The Hercules C. Co. is shipping high-grade copper ore from Morristown.—B. Ford will develop his prospects in the White Tank mountains.

Phœnix, March 6.

Mohave County.

(Special Correspondence).—The Tennessee drift on the 250-foot level of the Altata mine is cleaned out and work of driving ahead has begun.—Three shifts of men have been put to work sinking for water on the Manzanita mine. The shaft is 103 feet deep and the steam hoist at work.

The Elkhart mine has started work again under new ownership and management. Sinking from the 500-foot level of the shaft is in progress, with a small vein of galena in sight.

The Roger Boy mine will have its gasoline motor hoist set up over the shaft for work by April 1. The wagon road to the mine is half completed.—The Hunrath mine at Acme is having a steam hoist put in. The ore in the bottom of the shaft shows gold values.

The shaft on the Tennessee Hill mine at Snowball, owned by J. D. Jordan, is down 200 feet. Work of crosscutting to the veins will be started.—Two prospectors have made a gold discovery in Stockton Hill district, the vein being 4 feet wide and showing free gold.

W. H. Cushing, president of the Stockton Hill M. Co. at Stockton Hill, says he will start construction work on a zinc plant. The ores are to be separated by magnetic process.

The Buckeye mine at Mineral Park has been taken over by M. Neilson & Co. of Wickenburg under lease and bond. Work has started. The ores carry native silver.—Jacobs Bros. are putting in cyaniding tanks to treat their ores at Gold Basin.—L. Blakely, superintendent of the Virginia and Ramrod mines in Weaver gold district, has taken a year's lease on these two mines and the 10-stamp mill. He has put men to work.

H. H. Smith, part owner of the Great West gold mine in Minnesota district, says the crushers will be started this month on ores of that mine for cyaniding.—The gold and copper ores on the Planet mine on Bill Williams fork are showing payable values.

Chloride, March 7.

Pinal County.

(Special Correspondence).—J. McSherry of Kelvin reports operations resuming at the McSherry mines. F. Marion and L. Gilson have a lease on the upper levels of the Ray mine, and are taking out shipping ore which they will send out as soon as the Phœnix & Easteru Railroad is built into Kelvin. J. Elder reports making a new gold discovery, near Kelvin, showing a vein 8 feet in width carrying free gold.—A contract has been let for a 40-foot shaft on the Calumet mining claim, owned by W. F. Nichols.

Kelvin, March 5.

(Special Correspondence).—L. D. McClure is working on his group of gold claims in Butte district, east of Florence.—C. McCarthy is taking out shipping ore from his mines north of the Gila river, 20 miles east of Florence.

Florence, March 6.

Santa Cruz County.

Oil is reported found 5 miles northeast of Nogales, near Kelsey's ranch, and locations have been filed covering 7 square miles of ground, says the Oasis.

Yavapai County.

(Special Correspondence). — The Ideal mine has a shaft 250 feet, a drift 100 feet each way on the 200 level, 50 feet each way at 250 level. The ore is sulphide, averaging $18 in a 1-foot to 5-foot vein. Manager E. L. Sharpneck proposes to sink another 100 feet for development purposes, but will stope on the present levels. The work was started to test his patent steam stamp. One stamp was installed and has been working some time to the satisfaction of the inventor. It handles ten to twelve tons per day. When stoping begins two additional stamps will be put in. The plant is superintended by Geo. W. Sarano, R. J. Fitzgerald foreman.

The Home Run plant, property of the Douglas-Lacy Co., is another designed to practically demonstrate the value of a patent — this the Nissen process, where every stamp works in a battery by itself. The 6-stamp mill is designed to amalgamate and concentrate about fifty tons of ore per day, employing two new Standard concentrators, which turn out about twenty-five tons per month. The ore is a hematite and quartz, sulphide on lower levels. The shaft is down 400 feet on a 3-foot vein. There are 3000 feet of drifting on the 3rd level and 200 feet on the 4th level.

The Monte Cristo, under Foreman W. J. Casey, is down 400 feet in shaft and drifting to strike the ledge. It has an abundance of water to run the 10-stamp mill and concentrator. The values are in gold and silver, with some lead and copper.

The Cash, owned by the same company, under Foreman Bardshar, is taking out some high-grade gold, silver, lead and copper ore, which is amalgamated and concentrated at its 10-stamp mill. This property adjoins the Senator group of the Phelps-Dodge Co. on the Hassayampa, 3 miles from Walker. It has the advantage of cheap fuel, wood costing only $4 per cord. The mill stands in a forest of pine, and water for its operation is pumped from the 400-foot shaft. Yet another mine, the Catoctin, is being worked some miles farther down the Hassayampa. All are under the superintendence of Harrington Blauvelt.

The Arizona Groom Creek G. M. Co., just above the Monte Cristo, is doing development work and making a trial run of ore at the Gold Basis mill, which has been leased for the purpose. The intention is to install a mill as soon as it is determined what process the ores require. Superintendent Lon Hall is in charge.

Other properties in the vicinity, now idle but expected soon to start operations, are the Chicago, owned by E. M. Clark of New Haven, Conn., Superintendent H. H. Keays, which has a 300-foot shaft; the Midnight Test, Geo. Woods superintendent; the Little Dutchman and the Empire—all having 10-stamp mills and more or less development.

Chas. A. Behm is driving a tunnel into Spruce mountain on a vein of low-grade ore, now 315 feet in, with a like depth, to intercept a point on the ledge where the surface cropping is 20 feet wide, carrying good values in gold. The property consists of eleven claims, eight of which show mineral deposits of good size and value.

A mile west of the Senator, on a slope overlooking for miles the wooded valley of the Hassayampa, is the Century property, owned by Judge E. M. Sanford of Prescott. The property consists of twenty-seven claims. There is a fissure vein 18 feet wide, with 4-foot paystreak. It is the owner's intention to form a stock company, to be known as the Red Mines, on seventeen of the claims. At present there is a 215-foot shaft and 150 feet of drifting on the property.

A mile north of the Senator is the 10-stamp mill of the Gold & Copper Con. M. & M. Co., Manager A. J. Pickrell. The process is amalgamation, concentration and cyanide. The company, composed of New York and Chicago parties, R. A. Sweet, president and treasurer, owns four properties—one on Slate creek produces copper ore, while the Mill group, President group and Montana group, on the Hassayampa side, yield lead and gold. A wagon road leads from the two latter to the mill, a distance of 2½ miles. Transportation costs $1 per ton. There are two steam hoists on the property and a total of some 2 miles of development work. Operations have been suspended for several months, but it is proposed to resume in April.

Groom Creek, March 5.

(Special Correspondence). — The Oro Grande well on the Hassayampa river is completed, and work will be started on the pipe line from the well to the mill of the Oro Grande mine, north of Wickenburg.—The Whipsaw mine, near Briggs, is working men in the Atlanta shaft.—J. Robey is taking out ore from his mine on East Buckhorn gulch, which he is running through an arrastra.

Briggs, March 6.

(Special Correspondence).—At Walker, on Lynx creek, there is a prospect of activity. Within a radius of a mile there are six mills, the Victor, Mudhole, Pine Mountain, Penn M. Co., Milliken and Dixie. Of these only the Pine Mountain and Dixie are running at present. The former is in charge of J. S. Carmichael, and the latter is under lease to C. C. Stukey, who is milling ore from his Eureka property.

The Poland tunnel is being driven through the mountain to connect Walker and Poland by rail. A branch of the S. F. P. & P. Ry. connects Poland with the main line at Prescott, and on this branch line, only 12 miles from Poland, is the Val Verde smelter, which is just now being taken over by the Bradshaw Mountain Copper M. & S. Co., and will be put in operation; capacity, 1750 tons per day.

The Poland tunnel is an interesting bit of engineering. Started originally on the Poland side to tap the Poland ledge at 1000 feet, the first part was hammered out by hand through hard syenite. About three years ago the present company took over the property and projected a tunnel through the mountain, a distance of 8090 feet, designed to tap the hidden ledges and furnish an outlet for Walker, and incidentally to develop water. In all three designs it will be successful. Several ledges of greater or less value have been cut, and Superintendent W. J. Martin estimates that it will yield 300,000 gallons of water per day.

The tunnel on the Poland side for 2000 feet is 7x10 feet, designed for a double track, the same on the Walker side for 1500 feet, the remainder being 7x7 and single track. There is a grade of 1% for 6000 feet on the Poland side, the remainder being 3% in the same direction, so that water will flow from it by gravity.

There yet remain 900 feet to complete the tunnel and work is prosecuted at both ends—on the Walker side by three eight-hour shifts, and two shifts of eight hours on the Poland, giving a total of about 100 feet per week. Sullivan 2¼-inch drills are used, operated by compressed air, which is furnished by a 125 H. P. compressor in the Poland mill. The engineering has been done by I. J. Stauber.

The Poland mine and mill suspended operations last year on account of labor troubles and will not resume until after the tunnel is completed. There is a total of 8200 feet development work in the mine, which has been worked more or less for thirty years. The mill of twenty stamps and nine Wilfley concentrators has a capacity of 100 tons per day.

Other mines working in the vicinity are the Poland Extension under Superintendent J. Gray; the Oriental, Superintendent W. A. Kent, and the Old Mesa, Superintendent B. H. Gray. At present little work is being done in this section.

Walker, March 8.

CALIFORNIA.

Butte County.

The Spring Valley quartz mine, near Oroville, with adjoining claims, has been sold to the United G. & C. Co. for a cash consideration. The United G. & C. Co. is composed of Eastern men with offices at Chicago, Ill. The development work done on the property by the United G. & C. Co. during life of bond which has been taken up, consists of a tunnel 825 feet crosscutting the vein 360 from apex, showing vein 4 feet wide assaying $10 in gold. In addition to this they are prepared to work the placer ground. Ditches have been built and giants placed ready for hydraulic operations. The development work and the preliminary work for hydraulicking is under superintendency of E. M. Wilson.

It is expected the Bay Counties Power Co. will resume operations at French Creek about June 1, says the Oroville Mercury. Superintendent Albert is at Colgate putting in a dam that was washed away by the recent floods. From there he will go to Nimshew and then to French Creek.

El Dorado County.

The shaft at the Ida Mitchell mine, near Placerville, is down 165 feet.—The restraining dam for the Red Hill gravel mine has been inspected and approved by the California Debris Commissioner.—Superintendent A. Anable of the Rescue mine reports work progressing on the hoist.

Mariposa County.

The Champion mine on the Mother Lode, between Coulterville and Penon Blanco mine, is under bond to a company which is developing the ledge. They are down 100 feet and report having struck ore.—The Never Sweat Co. has made arrangements to start work.

Nevada County.

The shoot of ore struck last week in the south workings of the Eddy mine, near Nevada City, is being opened up. The mill is running on day shift. When the shoot is further developed the stamps will be dropped on night shift. The strike was made at a point 150 feet south of the shaft, says Superintendent Kirkham. The Eddy adjoins the Oustomah

mine, formerly the Pennsylvania, west of Nevada City.

The Mountaineer G. M. Co. has been incorporated under Arizona laws, with principal place of business Phœnix, by J. Bender of Hamilton, Ohio, F. Searls, J. C. Camphell and D. E. Morgan of Nevada City, W. T. Farrar, J. M. Duke and Geo. W. Henderson.

Tho aerial tramway connecting the Mayflower ledge at Maybert with the El Oro mill is again in working order and the stamps are dropping.——A cave at the Black Bear mine near Rough and Ready has temporarily stopped operations.

Work on the Round Mountain mine, near Nevada City, has been discontinued hy Huckins Bros. on account of water. The water has been coming into the shaft so rapidly that they were unable to handle it. They expect to put in a pump.

The mill of the Murchie Con. G. M. Co., near Nevada City, is in full operation, says Manager A. Maltman. The company is composed of San Francisco men. The main working shaft of the mine has a depth of 700 feet. It is of three compartments and is on the Big Bluo ledge. There is connected with it a 700-foot drain tunnel, 160 feet heneath the surface aud opening into Deer Creek canyon. Seven levels have heen opened on the Big Blue, and work is heing done in five of them. Over 4000 feet of lateral drifts and levels have heen opened. The 30-light dynamo used in lighting the mill will be supplemented by an 80-light machine for the hoisting works and the underground workings.

Nonsuit was granted on the 10th inst. in the action hrought hy G. E. & J. W. Riloy against the North Star M. Co. for $800,000, the plaintiffs alleging tbat the company had taken ore of that value from their mine at Grass Valley previous to April, 1899. The company stated that it had owned the Massachusetts Hill quartz mine for forty years, and that in working the mine it was entitled to follow to their entire depth all the veins, lodes and ledges containing gold which were embraced within this property, even though they led to the adjoining property of the plaintiffs. It appeared that the ore was taken in following the veins of the Massachusetts Hill mine, the court sustaining this contention. Attorneys for plaintiffs will appeal.

San Diego County.

The work of pumping the water out of the Owens mine shaft, near Julian, has heen completed.——Cook & Marlett report finding asbestos on one of their mining claims near Witch creek.

At Escondido arrangements are heing made for mining and quarrying of pelagonite, which will he used for making paint, talcum powder and ornamental stone for the interior of buildings. There are three claims, covering sixty acres of land, and owned by Oakland men. Thore is said to be a stratum of yellow ochre of good quality in theso mines.

Santa Clara County.

The first shipment of quicksilver from the San Juan quicksilver mine, 2 miles south of San Jose, was made last week. The shipment included 1200 pounds of quicksilver and represents a short run of the furnaces. The owners are Boston, Mass., men. The mine was worked in the early days by the Mexicans, hut has been idle for a numher of years. Men are increasing development. The old tunnel was opened and high-grade cinnabar found. Furnaces are heing huilt.

Siskiyou County.

J. E. Roherts and M. Smitbson are opening up the Know Nothing quartz mine on Know Nothing creek, ahove the Forks of Salmon.

Tuolumne County.

(Special Correspondence).—The Soulshy mine and mining property has heen sold to Eastern parties, who took charge March 1st, and H. L. Huston of Calaveras county is superintendent, with J. L. Cox as foreman. Five more stamps are heing added to the mill, making a total of fifteen stamps. The mine employs nfty men.

Soulshyville, March 7.

The Rawhide mine, near Jamestown, against which a strike is on hy the union, is running with sixty-five men. On the 6th inst. W. A. Nevills, owner, with a party of twenty strike hreakers, on going to the mine was attacked hy a mob of strikers, but they were heaten off hy the company's guards, armed with shotguns.

The Golden West mine, on the Comstock ranch, near Sonora, will he started up again, with F. McPherson in charge.——The Altadena mine, on the hill east of Columhia, is heing equipped with a boiler. When the machinery is set, sinking will he resumed.——The Evalina G. M. Co. has been incorporated hy J. P. O'Brien, C. A. Garter, M. S. Hamilton, W. J. Hayes and W. H. McClintock, of San Francisco.

The Evalina G. M. Co. has been incorporated, with principal place of business San Francisco, hy J. P. O'Brien, C. A. Garter, W. J. Hayes, W. H. McClintock of San Francisco and M. S. Hamilton of Oakland. They have taken over the Slap Jack mine and the Ora Vista mine, near Big Oak Flat.

It is reported that the Cherokee Group G. M. Co. of Boston, Mass., wbich operated the Laura and North Star mines a year ago, has reorganized and will start work in May.

The gravel mine ou the Doyle ranch, west of Columhia, was bonded last week to C. Sawyer of San Jose for $25,000. The Doyle ranch gravel mine is owned hy Doyle Bros. and is on the Tahle Mountain river channel.

Yuba County.

Marysville reports say 700 acres of the holdings of J. O'Brien were bonded last week to Eastern men. It will be prospected for dredge mining. On another part of the O'Brien land two dredging machines are heing built for the W. P. Hammon Co. These two machines Manager Cameron expects to have completed and ready to operate before July 1st, and two more will he started by his company before these are finished. The Whitney quartz mine, near Cabhage Patch, bonded by Marysville men, is being developed.

COLORADO.

(Special Correspondeuce).—Denver men consider the husiness outlook for Colorado is hrighter than for a year past. Reports are of a nature which tend to create confidence and a hetter feeling throughout the city and State. The president of one large manufacturing concern stated: "We feel greatly encouraged over the business we are receiving, and the numher of inquiries coming in for prices on our class of material. The inquiries we are getting to-day are of a different nature than the ones received last year. The ones we received last year were moro on the speculative order, while the ones we are receiving to-day are more stable and indicate renewed activity."

Lyman L. White, State Commissioner of Mines, has charge of the mineral exhihit to he taken to the World's Fair at St. Louis, Mo. He has secured floor space, 43x80 feet, in the Mines and Metallurgy huilding. The cases containing the specimens will he made of mahogany; the fronts will be of Colorado onyx and the sides of Colorado marble and onyx, with plate glass doors. The gold case will contain between $50,000 and $75,000 in gold specimens. One case will contain free silver specimens. There will be three cases of telluride ore from Teller and Boulder counties, heside a general exhihit typical of the State.

A movement is on foot to organize and operate a summer school of mining engineering. A large amount of money has been subscribed hy G. Crocker, through J. H. Hammond, for starting this school. Harvard, Yale, Massachusotts Institute of Technology, Columbia University and the School of Mines of Colorado are expected to take part in this enterprise. Thoy intend leasing a property and running it the samo as any other concern, and thereby give their students the henefit of practical mining experience. The details as to where this mine will be located has not been given out, hut is to be some place in Colorado. Prof. H. S. Monroe of Columhia University is to have charge of it for this summer.

Denver, March 7.

Clear Creek County.

(Special Correspondence).—The Idaho Springs M. & R. Co. has started up its mill under the management of J. J. May. They have several hundrod tons of ore on hand.

The Fostoria G. M. Co., W. Nichols superintendeut, will resume operations next week. Assays show this company has high-grade ore.

Idaho Springs, March 7.

Custer County.

(Special Correspondence). — Considerable development work is heing done and planued in Rosita district on properties which have heen idle. Work is progressing on the Humboldt-Pocahontas and the Merriment, as well as several other properties.

Rosita, March 5.

Gilpin County.

(Special Correspondence).—The Moffat road is within 10 miles of Rollinsville and affairs in northern Gilpin county and southern Boulder county are improving. It is expected trains will be running into Rolliusville by May 1st. The prospects and mines in that section are in about the same position as heretofore—waiting the completion of the railroad which will save a long haul to Black Hawk hy wagou. The mining camps such as Perigo, Gold Dirt, Gilpin, Gamble Gulch, Moon Gulch, Boulder Park, Mammoth Gulch, Phœnix, Baltimore, Eldora, Caribou, Cardinal and Netherlands, are from 2 to 6 miles from Rollinsville. Completion of the road to Rollinsville will mean cheaper coal for the mines. The Gold Dirt mine is opening up the 600-foot level east and west from the shaft. They have received assay returns from ore in the east drift at the 600-foot level which runs $8 gold, $21 silver, $4 copper. At the Perigo they are running the mill on one-half time, hut tbe numher of men will he increased. The Benton mine, which adjoins the Gold Dirt, has its shaft down 75 feet. The vein is 4 feet wide, in the bottom of which 2 feet assay 0.62 ounce gold and 2 feet 0.20 ounce gold. This property is equipped with shaft house, 70 H. P. hoiler, 25 H. P. douhle-geared hoist. Sinking will be resumed April 15th. Ore tested at the Perigo mill from the Benton, taken from the shaft and surface workings, averaged $8 per ton.

Rollinsville, March 6.

(Special Correspondence). — The Blue Grass M. & M. Co. is operating its mill and both tbe properties which it owns at Phœnix.

Phœnix, March 5.

The Black Hills & Denver M. Co. is driving work on its tunnel on the north side of Boulder park to cut a group of claims near Phœnix. The main tunnel is in a distance of 200 feet. J. Peterson, superintendent, says development will he increased. —— Two shifts are at work in the International tunnel up South Boulder canyon, which is in 50 feet. Kansas and local parties are interested and O. P. Caley is superinteudent.——Work is progressing on the tunnel of the Jenny Creek M. & M. Co., up Jenny creek, in Kansas district. The new line of the Moffat road will pass through the territory of the Jenny Creek Co.

Denver and Eastern men are interested in the Gilpin American M. Co., owning a group of seven claims near the head of Eureka gulch on King flats, near Nevadaville. The group has been partially developed with shafts of from 10 to 40 feet in depth, and it is the intention of the company to put up macbinery and sink a shaft near the center of the group.

The Golden Cloud M. Co., operating the Golden Cloud group at Russell Gulch, is increasing development work. The group consists of four claims, all patented and owned by Hawley & Potter of Central City. During the past month machinery has heen put in to sink the sbaft 1200 feet. H. G. Pearce of Denver is manager, with L. E. Tohias of Idaho Springs superintendent.

A two year's lease and hond bas heen given on the Columbine and East Columbine claims, in Pleasant Valley district, near Central City, to J. H. Camphell, of Russell Gulch. Work has been startod up in the main tunnel, wbich has heen driven in 125 feet, in the hreast of which there is a 14-inch streak of iron sulphide carrying values of $25 gold per ton.

Hinsdale County.

(Special Correspondence). — The Red Rover mine, which has heen closed down for several months past pending settlement of litigation, will he in operation again as the company is heing reorganized. Plaus for the smelter to he built at Gunnison are progressing. The Red Rover Co. is at the head of the smelter enterprise. G. J. Bancroft of Denver is consulting engineor for the company.

Lake City, March 6.

Lake County.

Manager J. A. Shinn reports his plans for the tunnel and tramway to he huilt by the Leadville-Denver M., T. & Tramway Co., near Leadville, are progressing satisfactorily. He says work will be started not later than June 1. The mines are in the Iowa gulch section and have heen hampered in their operations by tho conditions which prevail in that region in winter. No shipments have heon made for some time hecauso of snow and condition of roads. The tramway will enable these properties to ship continuously throughout the year.

La Plata County.

(Special Correspondence).—At the Bulldozer mine the number of men has been increased and shipments are heing steadily made to the Durango smelter. In the breast of the drift and stope is a hody of ore 3 feet in average width, which runs twelve ounces gold and twenty-five ounces silvor por ton, requiring little sorting.

Sinking has heen resumed at the Comstock mine and drifting continues on tbe 100-foot level, eight men being employed. Shipping ore is heing taken out, though the values are mostly in silver, the lost gold shoot not having yet heen recovered. The porphyry dike has heen crosscut for distance of 50 feet and is well mineralized. It is thought it will pay to cyanide entire.

The Bonnie Girl mine has discontinued building operations until spring, hut several men are completing excavations for the mill. The frame for the first unit is nearly enclosed and the pipe line has been laid.

The Neglected mine has temporarily reduced its numher of miners while the mill is husy working the dump of several thousand tons, and three shifts are sinking a new shaft.

At the May Day mine thirty men aro employed iu the mine and at the mouth of the proposed tunnel. The air pipe has been laid and the compressor is on the ground. A carload of ore recently taken out in sinking the shaft 3 feet notted $600 at the smelter.

The Chief M. Co., operating across the gulch from the May Day mine, cut tho vein last week and is taking out high-grade oro. The vein is 2 feet in width. Buildings are going up and machinery will he put in.

Mancos, March 7.

Pueblo County.

The numher of men on the payroll of the Colorado F. & I. Co., Puehlo, has heen increased to ovor 2000 hy the opening of the two hlast furnaces of the stoel works. The hins are full of coke and more is on the way. Coal shipments are assuming normal proportions, two trainloads per day arriving at tho plant. The addition of men is not directly at the furnaces. To operate one of these takes a small force of men, says the Pueblo Chieftain. Machinery has made it possible for thirty men in all to operate the largest of the furnaces, which turns out 350 tons of pig iron per day and consumes three times that tonnage in weight of ores, limestone aud coke. The addition to the forco is made hy putting to work yard men and reopening other departmonts dependent on the hlast furnaces. To provide steel for the different plants where the finished product is made, the converter will he started. Raw material will also be furnished hy the open hearth plant.

Rio Grande County.

A strike is reported in the Comet claim at Embargo camp, near Del Norte. The ore was opened up at depth of 51 feet, tbe vein showing 3 feet wide, giving returns of eighty-nine ounces in silver per ton. The Comet is owned by Beere, Smiley & Freman and A. Shippee. The ore is sulphide. Another strike in the camp was made in the Evening Star mine, of the Evening Star, Morning Star and Silver Moon group, owned by Beere and Beere, Smiley & Froman. At depth of 46 feot ore was uncovered assaying $18 across the vein for 3 feet.

Saguache County.

(Special Correspondence).—The owners of the Goldmont M. & M. Co. expect to start operations about April 1st. They will also huild a 150-ton mill.

Alder, March 7.

San Juan County.

E. C. Condit, manager of the Astor M. Co., oporating in Eureka and Picayune gulches, near Eureka, reports machinery and other equipment will be put in and development work increased. The properties consist of the Astor Nos. 1, 2, 3, 4 and 5, Sunshine, Fortune, Grand Mogul and others. The Sunshine has a 300-foot tunnel driven on the vein, made up of yellow and gray copper, iron, etc., and carrying both gold and silver. This ore is said to give average returns of $18 per ton. A shaft has heen sunk on tbe vein to depth of 70 feet, being in ore all the way down. Sinking was suspended hy reason of surface water having flooded the workings. The Grand Mogul, wbich has heen developod hy a 170-foot tunnel driven on the vein, is in 7 feet of mixed galena, copper and quartz, carrying gold and silver. The product of hoth these claims, and also of the entire group, is a milling proposition. A crosscut tunnel, which is in 850 foet, is heing driven to develop tho entire group. Among other improvements that have been put on the group is a powor plant comprising a water wheel, dynamo, a 25 H. P. hoist, one 10 H. P. pump, fau and two power drills. A 40-stamp mill will be put in and is expected to he completed hy Sept. 1st next. As soon as tho main vein is cut in the crosscut the numher of men will bo increased hy thirty additional.

It is reported the Hercules Con. M. & M. Co., on Sultan mountain, at Silverton, will he started up in April. This company owns thirty claims on that mountain which are developed by two crosscut tunnels aggregating 5000 feet, which cut the Hercules, Little Dora, Empiro, Victoria and other veins from 300 to 750 feet vertical depth below surface. The upper, or Montezuma tunnel, is 1800 feet in length, and the Empire, 400 feet below, is 2350 feet, with considerable drifting done on all the veins at point of intersection. The Hercules, where cut, shows an 8-foot vein, says the Times, wbile the Dora, Victoria and Empire veins are from 3 to 4 feet wide. The rock is a milling quartz with lead-copper ore running in gold and silver. Near mouth of Empire tunnel is the company's 100-ton concentrator, which is run hy water and steam power. The mill, mines, hoarding house and offices are heated with steam and lighted by elec-

tricity. The management of the Sunnyside mines, near Eureka, have been increasing their number of men, Superintendent J. Terry having 200 at work. This mine, the product of which is gold, is enlarging its output. The vein of the Sunnyside is 80 feet wide of milling ore, with a 6-inch shoot of high-grade ore. The mill at Eureka is handling 100 tons per day of ore, making daily shipments of concentrates. The management has plans drawn for improvements this summer, among which will be a compressor plant and driving of a tunnel to cut the veins at greater depth. When this is completed the mill will be enlarged to handle the increased output.——The contractors on the Silver Wing mine are pushing ahead the tunnel with air drills. The Eureka Exploration Co. owners propose extending this tunnel No. 2 to the Frederica ground, a distance of 4200 feet, of which 2250 feet has been completed, reaching maximum depth of 2500 feet. This will cut several mines with surface showings. The veins to be cut are either controlled by this company or the owners have contracts with the Eureka Exploration Co. for development of the claims through the tunnel.

Superintendent Umbell of the Henrietta mines of the San Juan M., S. & R. Co., near Silverton, last week put men to work on that group. This mine has been developed for the past three years by seven levels. At 120 feet above No. 7 level, in cutting for No. 6 station, the shoot of ore which the raise follows was opened, showing 5 feet of yellow and black copper ore, containing gold and silver values. The number of miners will be increased April 1st to fifty. Ground is said to be opened at the mine so that 250 men can be put at work to breaking ore. The smelting ore in the Henrietta mine will furnish iron-copper sulphides to keep the 150-ton pyritic smelter in operation, and at the same time give a market for quartz ores of the county. An aerial tramway from the mine to the Gladstone railroad, 5000 feet in length, was completed last fall.

San Miguel County

The output of the mines of Telluride district is at present 75% of the normal product, says the Telluride Journal. Part of this deficit is duo to the fact that a full force of miuers is not yet at work, and partly to a shortage of water for milling purposes.

Teller County.

The Stratton's Independence, Ltd., at Victor, is employing 440 men in two shifts. The company is shipping out an average of fifty tons of ore per day, which goes to the Black sampler at Goldfield. The oro is running one ounce gold per ton.

IDAHO.

Bolse County.

The Boston & Idaho Dredge Co. will build two gold dredgers next summer, one on Cold Springs flat, 6 milos below Idaho City, and the other at the junction of More and Elk creoks, at Idaho City. The latter will work on Elk creek. The dredger is expected to handle from 75,000 to 80,000 cuhic yards per month, says Superintendent R. Winters. The dredge company has been negotiating with the Oxbow E. Co. for electric power.

Custer County.

Smelting was discontinued during two days last week at the plant of the White Knoh C. Co. at Mackay pending alterations. The waters of Warm Spring creek were connected with the city water main, and the pipo line leading from White Knoh creek cut out and connected with the smelter. The new pumping plant which raises water from Lost river was connected with the smelter, and cut off provided for connecting White Knob water with the city water main in case of fire.

Idaho County.

(Special Correspondence). — Considerable snow fell in the district during February, and a number of slides occurred, resulting in death of two men.

Superintendent E. L. Abbott of the Sunnyside mine says the Burr Oak tunnel is in 1000 feet, with the face in granite with quartz stringers. Twenty-five feot per week is made with seven men. It is expected the ore body will be reached in 200 feet. C. L. Lovojoy, treasurer of the company, says it is the purpose of the management to equip the company's mines with machinery, etc. Manager R. W. Purdum writes that he will give his personal attentiou to the construction of the uncompleted wagon road to Roosevelt as soon as spring opens.

The Dowey mill has been running steadily this winter, and Superintendent E. Haug says work has not been interfered with by frost. The December and January clean-ups netted forty pounds of bullion each, the proceeds of milling with ten light stamps.

The Thunder Mountain Pearl M. & M. Co., organized at Pittsburg, Pa., has nineteen claims, extending on both sides of Holy Terror creek, 2 miles northwest from the Sunnyside mine. and three tunnels have been driven—100 feet, 135 feet and 250 feet, respectively. The bulk of the ore is low grade, but shows occasional high-grade shoots. The principal tunnel will be driven to 500 feet this winter. C. M. DeCamp is superintendent.——Tho Planet group of seven claiins, owned by W. H. Padgett and T. M. Shugre, is on Monumental side of divide, botween Monumeutal and Indian creeks, at elevation of 8000 feet. The main trail to Boise City passes through the group. Three tunnels of 45, 35 aud 60 feet have been driven. In the 60-foot tunnel assays show average values of $34. The ore is free milling and is a quartz-porphyry.

J. Pierson, superintendent of the Georgia Holts tunnel, driven for Hendricks & Bernard on Divide creek, says ores for assay wore sent out every 5 feet for tho full leugth of the tunnel, 75 feet, and returns give average of $3 per ton gold.——Development in tho Fairview mine shows the ore body 60 feet wide for length of two claims, averaging $10 per ton gold in value. Several talc soams were crossed. Ono of thom was 3 feet wide and assayed $56 per ton gold.

The tunnel on the First National mine on Trap creok is being steadily driven by Brown & Graham. Blue quartz is being taken out.——B. R. L. Poston & Co. havo driven a 60-foot tunnel on their group (Peak Point claims).——Bartholomew & Choate, in developing their group of three claims on Cinnabar creek, a branch of Sugar creek, have exposed a lead of quartz, carrying iron sulphides, which, concentrated, assayed $400 in gold.

Roosevelt, March 2.

W. D. Brown, manager of the Concord group, near Hump, reports preparations being made to sink on the Mother Lode No. 2, and work will be advanced by spring so machinory can be brought in over the snow and placed.

The Independenco mine, near Roosevolt, has let a contract to crosscut the ledge. This crosscut has already been driven through porphyry into tho vein matter. It is lutended to put in au air compressor. Two miles south of the Crown group, on Logan creek, is the Green property. A 200-foot tunnel has been driven on tho Empress. On the McKenzie group a tunnel has been driven 900 feet, and crosscuts aro heing run.——On the Wordenhoff group twenty men have been working all winter. Three tunnols havo been driven, each tapping hodies of ore. As soon as the nnmber of men on this mine is increased a tunnel will be started at the base of tho hill and driven in to tap the vein at a depth of 2000 feet, says Manager Hunt.

Owyhee County.

The Weaver dredgers on the Snake river, near Grandview, have been started.

Shoshone County.

The suit against the Empire State-Idaho M. & Dev. Co. at Wardner and C. Sweeney and F. L. Clark of Spokane, Wash., was settled on the 7th inst. in favor of K. Hanley hy Chief Justice Fuller of tho United States Supreme Court, who refused to give the Empire State Co. chance to reopen the case and refused the writ of certiorari for which it had applied. Hanley receives $260,241.83, one-eighth of value of ore taken from the Skookum claim, not deducting cost of taking out the ore.

The mines of the Cœur d'Alenes receiving electric power from the Washington Water Power Co., from Spokane Falls, are using something over 1400 H. P., says the Spokesman-Review. Of this the Standard is receiving 500 H. P. Tho electric power is used here principally for operating the compressor, which also supplies the Mammoth mine with power. The power is divided among the other mines as follows: Empire State mill, 160 H. P.; Bunker Hill & Sullivan, 150 H. P.; Empire State mine, 200 H. P.; Hecla mill, 100 H. P.; Tiger-Poorman mine and mill, 350 H. P.; Hecla mine, 200 H. P. At the Bunker Hill tho power is used to operate the electric mine railway, the sawmill and to light both Wardner and Kellogg. At the Tiger-Poorman the olectric pumps aro operated, and at the Hocla mino the compressor and the hoist. The Hecla is preparing to put in two electric pumps, one of which will use a 30 H. P. and the other a 20 H. P. They will have capacity of 150 gallons per minute.

KANSAS.

Wyandotte County

The Standard Oil Co., it is reported, will build an oil rofinery in Sugar Creek valley, on the Missouri river, 10 miles south of the business center of Kansas City, where 120 acres of land havo been bought. Surveyors are at work on the site, and it is expected the plant will be running by October next. Thore will be an acid plant, paraffine works, tallow works and other facilities for the manufacture of products from crude oil. The plant will, it is said, employ 1700 mon. A pipe line that will bring oil nearly 200 miles from Neosha is also to be built.

MICHIGAN.

Houghton County.

The annual report of the Franklin M. Co. at Hancock has been issued as follows: Copper produced, 5,309,030 pounds; selling price, 13.40 cents; yield, pounds copper per ton, 16.0; receipts, $685,841; expenses, $663,255.

The No. 5 shaft at tho Franklin mine was out of service temporarily last week because of a cave-in. This accident reduces the rock supply 100 tons daily.

The Atlantic M. Co., operating near Houghton, report for year onded Dec. 31, 1903, shows production of mineral was 7,670,660 pounds, which yielded 71.77%, or 5,505,598 pounds of refined copper, for which was realized 13.12 cents per pound. The production of minoral the previous year was 6,847,270 pounds, yielding 72.28%, or 4,949,366 pounds of refined copper, realizing 11.88 cents per pound. The copper yielded during the last year sold for $722,386, against $588,201 in 1902. After deducting oxpenses, interest on loans, construction and explorations and land sales, there remained a net profit for year of $150,342, against $1598 in 1902. The average yield of rock treated during year was 12.76 pounds of refined copper per ton, against 11.09 pounds per ton in 1902. The report says present appearance of the mine seems to warrant expectation that yield of rock mined during past year will be maintained during 1904. The explorations on section 16, in search of the Baltic lodo, have not so far been successful, and have heon discontinued, awaiting result of extension of workings in the Baltic mine towards that section. The compauy has sold the surface right to a portion of property on shore of Portage lako, near site of the old stamp mill, to he used as a site for smeltiug works by the Michigan Smolting Co. The company received in payment therefor $25,000 in stock of that company, by which holdings the Atlantic Co. will secure a lower rate for smelting than has hitherto been paid.

The annual report of the Osceola Con. M. Co., operating at Opechee, compared with 1902. shows:

	1903.	1902.
Gross receipts	$2,105,924	$1,594,453
Operating expenses	1,522,770	1,493,654
Construction	129,418	85,327
Tons rock stamped	924,400	836,400
Pounds mineral obtained	21,904,243	18,430,012
Per cent refined copper in mineral	73.317	72.797
Pounds refined copper per ton rock stamped	17.4	16.0
Production fine copper, lbs	16,059,636	13,416,396
Cost per lb, exclusive of construction	8.23c.	9.91c.
Cost per lb construction	0.81c.	c.64c.
Cost smelting, freights, Eastern expenses, commissions and all other charges per lb	1.25c.	1.22c.
Total cost per lb of refined copper	10.29c.	11.77c.
Cost mining per ton of rock, including stamping	17.44c.	21 735c.

The directors' report says the company did not begin to get full benefit of the new developments at the Kearsarge until August. Since it began paying dividends in 1878, the Osceola has paid $4,343,450. The North and South Koarsarge properties are turning out 3000 tons of rock a day, which runs at least 1¼% copper.

The Centennial, near Calumet, is raising from the twenty-fifth and oighteenth levels in B shaft. On March 1 they will start from the surface to sink through the shaft below. It is expected to be opened from the surface to the eighteenth level within six months. Tho hoist from No. 6 shaft in the old Centennial is to he brought over to B shaft when the latter is sunk through.

The annual report of the Franklin M. Co. at Hancock for year ended Dec. 31, 1903, with figures compared with those of preceding year shows:

	1903.	1902.
Receipts	$685,841	$647,964
Expenditures	663,255	508,270
Balance of assets	168,460	100,058
COPPER ACCOUNT.		
Copper produced, pounds	5,309 030	5,259,140
Copper sold, pounds	3,888,775	4,435,527
Copper on hand Jan. 1, pounds	1,420,255	823,613

Of the copper produced, 3879 pounds were taken from the sands. The amount stamped during tho year was 347,458 tons. The amount hoisted was 349,263 tons. The old Franklin still shows good supply of ore, owing to new openings, pillars, etc., discovered in and around old or abandoned workings in the old mine. Nothing of value has been found in the workings on the conglomerate lode east of the Pewabic lode. Franklin Junior is proving up satisfactorily. The No. 2 shaft has been started and both sinking and raising are going on. The No. 4 is installed and working. This and other improvments cost $41,803.68.

The Wyandot M. Co., near Winona, is drifting on a cupriferous amygdaloid bed 650 feet west of the Eastern Sandstone and getting a little copper therefrom, says the News. Winona is sending 150 tons of rock to the Atlantic mill daily and will resume sinkiug in the uew south shaft within a month.

The suspension of operations in the mines of the Copper Range Con. C. Co. at Painesdale is giving the company an opportunity to make repairs at the mill, and when operations are resumed tho company will be in position to secure better results than before the strike occurred, says the News. Work on tho compressor is progressing.

The Dollar Bay smelters shipped fiftoen carloads of refined copper east last week. Winter shipments by rail aggregate 10,500,000 pounds. Blizzards, with heavy snowfall in the copper district, blocked roads and interfered with rock traius.

The Winona C. Co., operating at Wiuona, report for the year ended Dec. 31, shows:

	1903.
Receipts	$247,252
Expenses	192,858
Copper on hand	28,926
Supplies and cash at mine	14,050

President J. Stanton's report says: The cost per ton of transporting rock to mill and treating 175 tons daily is more than it would he if they were ahle to treat 1000 tons daily in a mill of their own, but it has been deemed advisable to test the yield of the lode at various points to obtain a fairly accurate knowledge of tho copper contents in the kind of copper-bearing ground already encountered. Tons of rock stamped during the year at tho Atlantic M. Co.'s mill were 51,434. From this stamped rock 1,687,331 pounds of mineral was produced, yielding 61.45%, or 1,036,944 pounds of refined copper, or 20.16 pounds per ton stamped.

Keweenaw County.

Mohawk's third head at tho stamp mill near Allouez is working and No. 4 shaft is in operation.——The Ahmeek shaft is down 200 feet in copper. Allouez, sinking toward lodo, is down 466 feet and expects to strike tho lode Oct. 1 at depth of 1100 feet. The miners are trying for a record of 100 feet in March ou account of bonus offered by Superintendent Chynoweth.

Ontonagou County.

A mass of copper was struck in the Mass mine, at Mass City, last week which weighs thirty tons.——Sinking below the thirteenth level has been resumed at B shaft at tho Massachusetts mine of the Mass group. The company is confining its energies to development of the Evergreen lode, which is a producer of mass copper as well as stamp rock. The working force has boen reduced, there being hut 175 mon on the company's payroll. The mino is operating twenty drills, and the average cost of production since last June is reported not exceediug 10 cents per pound. The coming year will witness development of C shaft.

The Victoria C. M. Co. at Victoria has won its contention that it has the right to use the system of compressing air by falling water for othor's use as well as its own, says the News, the question having arisen with the owners of the patont. The company will continue sinking the 20x20 main power shaft. The mine is said to have 25,000 feet of openings and sufficient stoping ground in sight to run one head five years at the rate of 300 tons a day. Drifts are being extended to the line of shaft No. 3, which will bo the main shaft of the mine, 1190 feet west of No. 2. The 3000-foot conical drum hoist on the ground for No. 2 will he set as soon as the weather moderates, when the hoist now in use at No. 2 will be set for No. 3, and sinking from the surface and raising from levels will be started simultaneously. The west drifts of tho mine look better than the east, the copper shoot making to the west.

MONTANA.

Fergus County.

It is stated the New Year mine, near Lewistown, will bo started up again the coming spring. Manager Nelson et al. of the St. Paul mine expect resumption of milling. Suporintendent J. Meredith, who has been at New Year since the shut down, has been doing development and assessment work and has opened up bodies of ore.

Jefferson County.

The Gold Bond G. M. Co. has been organized for developing properties in Jefferson county a few miles south of Helena with main office at Helena. They will operate properties 2½ miles south of Helena and the Good Cheer group on Maupin gulch, Jefferson county.

Lewis and Clarke County.

The Gold Band M. Co. has been organized to operate fifteen claims, one group 2½ miles south of Holena and the other 15 miles from Helena. J. Winscot is president and manager, at Helena; G. D. McKay of Aurora, Ill., vice-president, and E. S. Hobbs of Aurora secretary and treasurer. The properties consist of the

Tunuel lode, near Helena, and tbe Good Cheer group, in Maupin gulch, on which work has heen done. There is said to be a lead of payable ore from 3 to 5 feet wide which assays as high as $20 per ton. There is a sbaft 60 feet deep, which will he sunk 200 feet. The Tunnel lode mine is east of the Wbitlach-Union and adjoining the McClellan.

Teton County.

J. Jardine of Great Falls, secretary of the Montana Swift Current Oil Co., reports having struck oil at the holdings of the company at Altyn, near the Canadian line. Oil-bearing shales were found there a year ago, and the company organized, with headquarters at Blackfoot, to develop tbe section.

NEVADA.

Elko County.

Mining at Bullion, Railroad district, 30 miles soutbwest of Elko, bas heen resumed. A company of California men bas bonded the Weston & Frank group and has started development work under Superintendent Knutzen.

Esmeralda County.

W. R. Smith, who has a lease and bond on tbe Copper Contact group near Sodaville, says work is progressing. Bismuth ores have been found.

Tbe owners of the Jumbo mine at Goldfield, Kernick, Taylor, McClelland & McKane, have let leases on their mines. The leases are let in 100x600 feet blocks, the owners retaining 400 feet at the point at which the shaft is sunk. Arrangements are also heing mado to lease tbe other five claims of the Jumbo group, and they will he divided into 200-foot blocks along the ledge, says tbe Bonanza. The royalty being asked is 25%.

Douglass gold camp, 8 miles west of Sodavillo, is again opening up. Adjoining the Douglass group of mines, wbich, witb its 5-stamp mill was recently sold to the Pan-Tonopah M. Co., is the Bounce mine. Tbe Bounce was sold last week to the Silver Star-Tonopah M. & M. Co., a Washington corporation, says Superintendent M. Averill. He will start work tbis montb. Arrangements are being made by which the ores from both companies' minos will be worked by tbe 100-ton reductiou plant to be erected on the ground at Douglass.

Water in Tonopah is said to be selling for 1 cent per gallon or $1 por barrel. There are two puhlic wolls at Goldfield and water is free. Wood is $12 per cord. It costs 25 cents a span to water horses, writes a correspondent to the Lewiston Tribune. There has been no snow tbere this winter. Iu two months they bave seen but four partly cloudy days and not a drop of rain or snow. The dust is heavy. The freight teams can be seen for 20 miles by the dust they make. Values are mostly in gold and higb assays have beon obtained. Thore are no mills thore yet, so all tbe ore is shipped to smelters, it costing $50 a ton to get it sacked and treated. The Combination is the heaviest shipper and their ore nets $300 per ton. They aro down 100 feet and have drifted 50 feet one way and 100 feet the other. The ore of the camp is mostly free milling. Wages are $4 and $5 per day for miners and $6 for carpenters and cooks. Board is $1.50 per day and $1 for a bed iu a tent. It is a tent town as yet, hut a few frame houses are being built. Lumber costs $75 a thousand. There are a great many freigbt teams on tbe road.

Humboldt County.

Superintendent G. Wilson of the Sheba mine, near Mill City, says the mill is again in operation.

Lincoln County.

Tho Frederick Warde G. & C. M. Co. of Salt Lake City, Utah, has been incorporated to operate in the Yellow Pine mining district by F. Warde, M. E. Mulvey, A. W. Rayhould and J. Moyers.

Nye County.

At the Midway mine at Tonopah the shaft has reacbed depth of 635 feet, where a station is being cut, from which crosscuts will be run north and soutb. This depth is equal to 700 feet in the Mizpah. On tbe 535-foot level a raise is being run from the drift in the south cut and ore is heing taken out. A raise bas also been started in tbo drift 35 feet north of tbe shaft, and as soon as enough ground has been opened up stoping will follow. It is expected tbat a run of Midway ore will be put through the custom mill this month.

C. S. Lemon of tbe United Tonopah M. Co., near Tonopah, will resume work on tbe company's group. The main shaft when work suspended was down 300 feet and was in ore. Another ledge has been cut on tho surface 200 foet west of tho shaft house and shows gold values.

The Montana-Tonopah M. Co. bas just received patent for its group of claims at Tonopah, said to be the first patent issued for property in Tonopah mining district.

Storey County.

It is reported the San Francisco men who bold a hond on the Keyes-Graessler mine in Seven-Mile canyon, near Virginia City, will resume operations.——Drill hole No. 7 on the Brunswick lode has been abandoned and the casing is being pulled. The bole was down 807 feet with bottom in porphyry.

White Pine County.

At tbe Rocco-Homestake mine at Hamilton the hoisting works are completed and will be put in operation this week.

NEW HAMPSHIRE.

Carrol County.

Several Boston men have been operating for a year, under the name of the Diamond Ledge G. M. Co., a property in Sandwich, 7 miles north of Center Harbor and Lake Winnepesaukee. The property comprises 100 acres on a hill. The vein is quartz, with a dike on the footwall 100 feet wide on the top of the hill. Five hundred feet below the top a tunnel 9x9 feet bas been run on the banging wall 125 feet. A crosscut is to be run at 150 feet to prove tbe width of the vein. Two bundred tons of gold-bearing quartz are now on the dump. Tbe breast of the tunnel is in ore running $5 per ton.

NEW MEXICO.

Roosevelt County.

The Portales News reports finding gold and copper-hearing ore hy M. L. Moody, 12 miles west of Portales.

Sierra County.

M. H. Steanghue et al. of Charleston, W. Va., bave taken ovor the Good Hope and Bonanza mines at Hillsboro and development work will be started this week. These properties are east of and in the first gulch from the Richmond mines.——Tbe Bigelow G. & C. M. Co., composed of New York and New England men, with W. Buchanan of New York as president, bas been organized and bougbt eight mines at Hillshoro, including the Dell, El Dorado, Opal and Oregon, covoring four parallel fissure veins for 6000 feet. Development work bas been goiug on in tbis group since last Octoher and on a body of ore. In the El Dorado, the soutb extension of the Richmond lode, tbe vein is showing 12 feet in width and of milling ore, with a sboot of shipping ore 1 foot in width that runs $30 per ton. Manager R. H. Hopper is blocking out the oro preparatory to building a mill.

W. W. Williams of Hillsboro, with New York and New England mon, has organized the Black Peak G. M. Co. to take over the Williams, McVey & Pretter group of tbree mines near Hillsboro, on wbich development work is done. He will block out the ore bodies before putting in machinery.——The Empire G. M. Co., composed of Western men, has bought tho Lilly mines of the West group, west of the Richmond group. This company is doing development work hy sinking and drifting on the ledge, wbich is sbowing up 3 feot of shipping ore. J. Kesser is manager.

OREGON.

Baker County.

A reduction plant will be built at the Imperial mine in the spring, says A. M. Paul of Sumpter, manager.

Tbe 20-stamp mill of tbe E. & E. mine at Bourne has been completed and put in operation.

Enlargement of the Friday working shaft, near Sumpter, is in progress, reports Superintendent Jackson. Tbe sbaft is being made double-compartment. The work has progressed down 50 feet.

Josephine County.

F. H. Osgood of Seattle, Wash., who bought the Hammersley mine in Jump-Off-Joe district, near Grant's Pass, reports work progressing in clearing out the mine. Two pumps, discharging 8000 gallons of water an hour, are lowering the water in the tunnels, drifts and stopes of the Hammersley. The timbering is said to be found in good condition. Tbe mine is equipped with a hoist, 5-stamp mill and concentrator. There are three boilers. The ledge of the Hammersley is 1 to 3 feet in width and tbe values are free-milling.

The Copper Eagle M. Co. is clearing a site preparing to huild a 50-ton smelting and matting plant at the Copper Eagle mine of Galice Creek district, near Grant's Pass. There are four claims (oigbty acres) in tbe Copper Eagle group, and the ledge bas an average width of 4 feet, carrying values in copper and gold, with some silver. Some 300 feet of tunnel have heen driven and one tunnel, in 200 feet, will tap the main lodge at deptb of 250 feet. Tbe property is being developed aud equipped under the mauagement of J. C. Mattison of Galice.

SOUTH DAKOTA.

Lawrence County.

A station is being cut at 800 feet in the shaft of tbe Oro Hondo M. Co. near Kirk, preparatory to drifting. The sbaft has during the last two months opened up free-milling ore.

The Capital City G. M. Co., incorporated last summer for operation on property along Deadwood gulch, near Deadwood, is preparing to put in boisting machinery.

Tbe Homestake cyanide plant No. 2, at Blacktail station, near Lead, on the north end of tbe Homestake property, is baving its tankage capacity increased by 1250 tons. There are five vats in tho plant, each of wbich is to receive an addition of 250 tons to its capacity, says the Black Hills Review. Tbis work is being conducted so as not to interfere witb operations of the plant. The Homestake Co. is increasing its entire cyanide plant capacity. For several months cyanide No. 1 at Lead has heen in course of enlargement. No. 1 will receive six additional vats which will double its capacity. The enlargement of No. 1 is for the purpose of giving more time for leaching of tailings from the mills on that side of tbe property, wbile in connection witb the enlargement of No. 2, there is a plan for the re-arrangement of the mill to permit introduction of a special process for tho treatment of some ores that will not admit of the usual metbod with tbe desired degree of success.

TENNESSEE.

Polk County.

Tbe annual report of the Tennessee C. Co., operating at Ducktown, shows the average price of copper which the company sold to have been 12.98 cents a pound. Tbe directors' report says that with the third furnace and the blowing engine, wbich will be in operation the last nine months of the current year, a production of 14,000,000 pounds of copper may be expected, as against 10,000,000 pounds produced in 1903. The company is to smelt "green" ore this year, which will mean a saving in cost of copper of 1 cent a pouud. The smelter will be enlarged from three to six furnaces, which will ho capable of treating 600,000 tons of ore per annum. The mines at present aro being worked only on day shift. Tho new construction will be extended over a period of eighteen montbs and will he provided for out of earnings.

UTAH.

February in the ore and bullion markot closed on settlements aggregating $1,793,500, notwithstanding heavy storms and bad roads, that at intervals made it impossible for producers of some of tbe camps to reach the bins, says the Salt Lake Tribuno. During tbe same period there was forwarded from the independent copper furnaces of the valley 2,921,642 pounds of coppor bullion, containing gold and silver, and of value of $876,492, without reference to bullion piled up in each of the storobouses. In addition to tho ores reduced at home, thore wore 6000 tous shippod to furnaces witbout the State. At every plant in tbe valley, witb one exception, enlargements aro in progress. The Yampa smolter at Bingham is getting into full operations, and the concentrators at the Utab C. Co., tbo Honerine and tho Ohio Co. are in commission. The output of copper bullion reached the total, from all sources, of 3,651,642 pounds, as comparod witb 2,736,590 pounds for tbe corresponding month of 1903, being as follows:

Bingham Con	742,682
Utah Con	1,206,000
United States	972,960
Total for independent plants	2,921,642
American S. & R	730,000
Total	3,651,642

Tbe total daily tonnage of ore handled by tho smelters was 3200 tons, making aggregate of 88,700 tons of ore reduced to bullion or matte during the month.

Beaver County.

Dovelopment has been resumed at the properties of the Galena M. Co., 3 milos north of tbe O. K. group in Beaver Lake district, near Milford. Ore has heen sbipped netting the company $60 per ton, witb silver-lead values. Tho management is drifting on the ledge at tbo 100-foot levol, and opening bunches of ore, wbich show forty-one ounces silver and 30% lead.

The management of tbe Horn Silver mine of Frisco closed month of February with an output of 1600 tons of ore, divided between lead and copper, and of whicb there were eighty tons of concontrates. Tho lead ore contains 3% coppor, witb some silver. The concentrator at the mino is idle at present, but will be oporated again as soon as supply of milling oro justifies.

Grand County.

In Miners' basin, near Basin, iu the La Sal mountains, the Grouse Mountain M. Co. is arranging for building a 100-ton plant in the spring, says W. R. Wbeat. He bas started work on the mill foundations and will have the machinery in transit at tbe appointed time. The Grouse Mountain mill will be similar to the Interstate cyanide plant in tbo same section, with provisions for increasing the capacity if required. Work in the Grouse Mountain tunnel in Miners' basin has heen progressing all winter. A number of small veins havo been crosscut. —— In Gold basin, where tbo Interstate M. Co. is operating hy tbe erection of a cyanide plant, as woll as developmont in its mines, J. H. Clark, manager, says they are getting out lumber for tbe buildings and making otber preparations for completing the mill in the spring. Two shifts are at work on the Iuterstate mine blocking out ground by tunnels and drifts. It will be brokon down and transportod to the mill by a tramway. Manager Clark says he has 3000 feet of development work done on tbe Interstate, wbereby two veins have been opened up, and from two sources a hody of cyaniding ore is exposod for 450 and 350 feet respectively. The mill will bave a daily capacity of 100 tons. He expocts to havo his mill in oporation by July 1st. The principal part of tho machinery is on the ground. The Interstate M. Co. is composed of Centerville, Ia., men.

Juab County.

Manager M. C. Fox of the Euroka Hill mino of Tintic, noar Eureka, says the mill on the property will bo put in operation again.

The Eureka Hill M. Co. mill at Tintic, near Eureka, will bo put in operation again, says Manager M. C. Fox. Low-grade ore has been blocked out in tho mine since the plant was closed down.

Piute County.

Work of running tho new tunnel on the L. & N. ground of tbe Franklin group, near Marysvale, has started. This tunnel will be driven 3000 feet to tap the ore body ou the othor sido of tbo ridgo from that in which the striko was made.——McCullough & Newton have hought the Cottonwood Spring mineral ground, 2 miles south of Monroe. Tbe work of same parties on tbe Independence mino, in Dry creek, is progressing.

Salt Lake County.

As soon as tho roads are in condition to permit of hauling over tbem, the Dowey mill at Bingham will be started up again. Tho Red Wing Extension and tbe Butler-Liberal mines will send their ore of milling grade to this plant to keep it running steadily. The Dewey is a custom mill and bas aided greatly in the development of tbe smaller mines of the Bingham district, as it bas provided a market for ore that would not pay to ship, and which otherwise would have remained in the ground or on the dumps.

Tbe tunnel of the Old Evergreen mine in Big Cottonwood canyon, near Alta, has heen completed to length of 1100 feot.

W. Ochs of Salt Lake City, who has a bond and lease on tho Rob Roy group of claims, near Bingham, says extonsivo development work will begin on the Rob Roy this spring. It is soutb of and adjoining the Bingham & New Haven ground.——Work will he resumed on the Congor group, near Bingham, this spring. A new pumping plant will be put in, as the mino is filled with water.

Summit County.

The daily output of concentrates from the Kearns-Keith mill at Park City has been increased from twenty to forty tons, by putting on a night shift.

The J. I. C. mine at Park City closod down last week for an indefinite time, says Secretary Wilkinson. Tbe pumps have been taken from the mine, leaving tbe shaft and workings below tho 400-foot level to be filled by water. The shaft is down 600 feet, with considerable development on the 400 and 600-foot levels.

Tooele County.

Manager J. J. Trenam of Salt Lake City, of the Stockton G. M. & M. Co., operating at Stockton, says large bodies of milling ore have been developed, but no steps as yet have been takon towards providing facilities for treatment. The matter of providing water supply has received attention in the meantime.

The Honorine West M. Co. bas been incorporated to develop a group of twenty-three mining claims, covering 200 acros of mineral land, which adjoins that of tho Honerine M. Co. at Stockton on tho west. The Bunker Hill, the Little Jessio and several others of tbe Honerine West's group were formerly worked till water interfered in depth. Tbe ground has been uuwatered hy the Honerine tunnol. It is intondod to tap and explore tbe ledgos hy which tho territory is traversed tbrough a main shaft on Jossie ground. In tbe system of veins within tbo Honerino West are said to be included the Ada, tbe St. Patrick and Hercules on the north of the Honerine, with four cross fissuros on the soutb. The waters in the Jessie's old

workings have receded so far that the management expects to reach the Honeriue tunnel level, 700 feet below, without need of pumps. B. F. Bauer, F. C. Richmond, M. H. Soules, S. V. Ham and E. J. Raddatz are directors.

Washington County.

Two cars of copper bullion were forwarded to market last week by the Dixie smelter, near St. George. This company is employing seventy-five men at its mines and smelter, and the shaft has reached depth of 775 feet.

WASHINGTON.

Okanogan County.

The Ruby mines' tramway at Similkameen, near Loomis, is completed and in operation. The Ruby is sending forty tons to the mill at the Golden Zone mine to be concentrated. The Prize Co., whose mill building is partly up, has its sawmill cutting 3000 to 4000 feet of lumber a day under Superintendent W. Fishburse.

Whatcom County.

Mining companies operating in Mount Baker district, east of Whatcom, will install an aggregate of at least forty-five stamps and a cyanide plant this year. The companies are the Great Excelsior, Mount Bakor and Nooksack. The first-named will put in forty stamps, the Mount Baker five; and the Nooksack will put in a cyanide plant. The American Eaglo is considering a 20-stamp mill. The First Chance mino proposes putting in a 10-stamp mill before the closo of the year and the Red Mountain G. M. Co. has also been considering such a proposition. The Mount Baker & Shuksan M. Co. may begin work on a reduction plant before end of year. It is claimed enough work has been done on its Red Crest group to show that a 10-stamp mill will yield $400 per day in free gold and $600 in concentrates. Some of theso improvements are dependent on railroad extensions into that district. The Mount Baker M. Co., H. Hahn president, has headquarters at Portland, Or.; the Red Mountain Co., C. Campbell manager, has offices at Everett, Wash.

WYOMING.

Carbon County.

J. Ranking has men at work in bis copper mine north of Rawlins. The ore is boiug sacked and shipped to a Denver, Colo., smelter.

FOREIGN.

AUSTRALIA.

Western Australia.

Bewick, Moreing & Co. report the following December output and costs for Western Australian mines of which they are managers:

Cosmopolitan Proprietary.—Cost per ton mining, 7s 4d; cost per ton treatment, 7s 4d; cost per ton general expenses, 1s 2d; total working expenditure, £6388; total development expenditure, £3501; total other capital expenditure (machinery, plant, etc.), £326; total expenditure treating accumulated slimes, £466; total receipts, £20,064.

Bollevue Proprietary.—Cost per ton mining, 12s 3d: cost per ton treatment, 7s 7d; cost per ton general expenses, 2s 1d; total working expenditure, £2225; total development expenditure, £2381; total other capital expenditure (machinery, plant, etc.), £1486; total receipts, £5488.

Sons of Gwalia.—Cost per ton mining, 11s 11d; cost per ton treatment, 5s 11d; cost per ton general expenses, 2s 2d; total working expenditure, £7869; total development expenditure, £1975; total other capital expenditure (machinery, plant, etc.), £820; total receipts, £21,221. Ore treated, 7869 tons; yield, 4136 ounces; tailings cyanided, 4350 tons; yield, 915 ounces, concentrates treated, 116 tons; yield, 574 ounces; total return of gold, 5613 ounces.

Vivien.—Cost per ton mining (including pumping), 9s: cost per ton treatment, 6s 9d; cost per ton genoral expenses, 1s 7d; total working expenditure, £1050; total development expenditure, £401; total other capital expenditure (machinery, plant), £1122; total receipts, £2344.

Lake View Consols.—Output, 8245 tons for 4248 ounces of fine gold; working expenses for month, £11,521 (£1 7s 11d per ton); estimated profit, £3446; expenditure authorized for new plant, £1155.

Oroya-Brownhill.—Working expenses, £9015 (£1 5s 8d per ton); development and capital expenditure, £4757.

Great Fingall.—Working expenditure, £7377 (17s 2d per ton); development and capital expenditure, £6742; receipts, £48,374.

The Ivanboe Gold Co.'s December output and costs were: Battery, 12,223 tons for 4247 ounces gold; sands, 6500 tons for 2164 ounces; slimos, 5652 tons for 2203 ounces; concentrates, 671 tons for 1832 ounces; telluride ore, 247 tons for 396 ounces; total, 12,476 tons for 10,842 ouncos; mining expenditure, 12s 0.9d per ton; reduction, 11s 8.5d per ton; general expense, 2s 2d per tou; total working cost, £1 5s 11.4d per ton, or a total of £16,180; development, £3060; machinery and plant, £400; London and Melbourne expenses (estimated), £425.

At the Queensland Menzies mine at Menzies the new 10-head battery is crushing ore, says the Western Australia Journal. The stamps weigh 1250 pounds each. There is but one mill on the fields with heavier stamps, the Millionaire, at Mount Morgans. The two drifts have been connected.

BRITISH COLUMBIA.

Boundary District.

The management of the Granby is working on plans for an eight-furnace addition to the Granby smelter at Grand Forks, which would increase its capacity from 2100 tons to 4800 tons a day, says J. P. Graves, manager of the Granby Con. M., S. & P. Co. H. N. Caler, assistant manager, has completed the surveys.

In No. 4 tunnel of the Granby mines at Phœnix, which was started last month, work is proceeding steadily, and the face is in 160 feet. The tunnel, which is being driven on a 5% incline, is expected to reach the 300-foot level of the Old Ironsides mine.——With plenty of cars available, ore shipments from the Athelstan mine, in Wellington camp, are heavier than previously. Twenty horses are used in bauling the ore from the mine to the Winnipeg spur, a distance of 1 mile, whonce shipments are made to both the Granby and Greenwood smelters. G. H. Collins is superintendent, with twenty-five men at work.

G. W. Rumberger and T. Rodorick of Phœnix have bought one-half interest in the Summit, Hopeful and Mayflower claims in Summit camp. D. McInnis, also of Phœnix, owns the other half interest in the group. Work will be started this month.

East Kootenay District.

Fort Steele reports say developments will be renewed this year on Wild Horse creek. Since the English companios abandoned operations the ground has been worked by a number of Chinese with success. It has been decided by the Bong Quong Placer Co. to work the ground abandoned by the Thompson Co. on the Invicta claim. The bank upon whicb it is proposed to start is 100 feet high, and most of the pay is said to be on the bedrock. An upper line of sluices will be put in to run off the surface, with a fall and a dump that will cbeapon the work. This work will occupy nearly two years, after which the line of sluices will be lowered to work out the bottom of the pit. Fifty-two thousand feet of lumber has been bought to carry out the improvements on the Invicta claim.

The annual report of the Crow's Nest Pass Coal Co., Ltd., shows progress made during the year in the permanent development of the company's properties at Coal Creek, Michel and Morrissey. It was not until Feb. 1, 1904, that the mines at Coal Creek, wbich had been damaged by the explosion of May 22, 1902, were fully restored. During the year nearly $1,000,000 have been spent on plant, development and machinery, adding to the efficiency and capacity of the mines and of the operating and coking plants.—— Coal produced during 1903 amounted to 661,118 tons, as comparod with 442,049 tons in 1902. Of this tonnage 279,334 were sent to the coke ovens, and produced 167,989 tons of coke, as against 121,000 tons made in 1902, while the balance, 381,784 tous (with the exception of 22,833 tons consumed under the boilers) were disposed of as merchantable coal.—— The mines opened during the year were: At Coal Creek three, at Michel two and at Morrissey two.—— Construction of 492 ovens was started during 1903, being 252 at Michel and 240 at Morrissey. Of these, 198 at Michel and 148 at Morrissey were completed, bringing the total number of finished ovens up to 982. The remainder of the ovens will be completed this spring.—— Net profits as a result of the year's operations amounted to $310,492.28.——It has been found desirable to acquire the branch railroad between the main line of the Crow's Nest Southern at Morrissey Junction and the company's mines, a length of 5 miles, for which a charter was obtained from the British Columbia Legislature last year. The holdings of the company cover 250,000 acres of coal and timber lands. The company has installed three water-works systems, besides electric lighting plants and a telephone system. T. R. Stocket is manager.

Nelson District.

Developments on the Gold Cup mino at Ymir are progressing. The winze has been sunk to 65 feet below the 125-foot level. This winze is in oro, the vein averaging 4 feet in width, with shoot of high-grade ore. The adit which taps the shaft at the 125-foot level is 260 feet long, and is in ore for greater part of distance. The ore varies in width from 6 inches to 6 feet, and contains bunches of telluride. The experimental mill has made a trial run of eighty-five tons with satisfactory results. The ore is a white quartz, impregnated with iron oxides and copper sulphides. These are saved on concentrating tables. Wollle & Dawault, who have the property under bond, propose building a larger mill, to be driven by water power from the Salmon river, on which water rights bave been obtained. They will also put up au aerial tramway.

West Kootenay District.

Placing of machinery at the Silver Cup reduction works, near Forguson, is going ahead. The electric plant which will supply motive power and light will be ready for operation next week. Tho outdoor work, except stretching of wires, is done.

P. to 85 H. P. Cuts of engines, hoists and ships' windlasses are also showo. The vessels include both single and twio-screw propeller types, and a variety of craft for hoth business and pleasure.

Latest Market Reports.

SAN FRANCISCO, March 11, 1904.

METALS.

SILVER.—Per oz., Troy: London, 26 7/16d (standard ounce, 925 fine); New York, bar silver, 57⅜c, refined (1000 fine): San Francisco, 57⅜c; Mexican dollars, 46½@47½c San Francisco, 44½c New York.

COPPER. — New York: Standard, $12.50; Lake, 1 to 3 casks, $12.50; Electrolytic, 1 to 3 casks, $12.62½; Casting, 1 to 3 casks, $12.37½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 15s spot per ton.

There appears to be little confidence in higher market for copper. A New York commercial paper says "the stocks of standard copper in Europe are light and the statistics show that the consumption during the past month has heen very good. The heavy shipments during the past two months have possibly in a measure satisfied the immediate requirements of that trade, though reports emanating from Europe do not show that consumers are as anxious to place orders as they were a short time ago." Following are the exports of copper for February in long tons: United Kingdom 4883, France 2871, Germany 1628, Holland 4864, Belgium 120, Austria 1261, Italy 948, Russia 165, sundries 102, a total of 16,842.

LEAD. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4⅜c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.85. London: £12 ₱ long ton.

SPELTER.—New York, $5.10; St. Louis, $5.00; London, £22 5s ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.00@28.40; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 31c; less, 32c; har tin, ₱ lb., 32½@35c. London, £123 15s spot.

PLATINUM. — San Francisco, crude, $18.00 ₱ oz.; New York, ingot, $19.00 ₱ Troy oz. Platinum waro, 75 @ 82c ₱ gram.

URANIUM.—Oxide, ₱ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING MARCH 1, 1904.

753,652.—DECORTICATING MACHINE—W. H. Allison, S. F.
753,532.—BOOTHEEL — F. F. Anderson, Oakland, Cal.
753,655.—SEAM RIPPER—M. J. Bacon, S. F.
753,465.—SPOON—B. H. Bennetts, Tacoma, Wash.
753,468.—PLOW—G. L. Bradley, Pataha, Wash.
753,541.—WINDMILL—W. A. Butler, S. F.
753,825.—OIL BURNER—L. E. Coleman, Santa Ana, Cal.
753,549.—BRAKE LEVER—R. W. Cooke, Condon, Or.
753,672.—CIGAR CUTTER AND LIGHTER—Coombs & O'Connell, S. F.
753,693.—NURSING APPLIANCE—A. S. Dixon, Los Angeles, Cal.
753,479.—WINDOW—A. F. Enquist, S. F.
753,790.—ROTARY ENGINE — A. F. Ford, Colfax, Wash.
753,565.—SAW FILING GAGE—S. J. Galloway, Hillsboro, Or.
753,697.—MOWING MACHINE—J. T. Gillaspy, Union, Or.
753,828.—PUMP—J. Hahn, Los Angeles, Cal.
753,489.—WRENCH—A. Heberer, Alameda, Cal.
753,493.—TELEPHONE—S. C. Houghton, S. F.
753,709.—BASE FOR POLES—G. H. Jones, Salem, Or.
753,716.—CARBON RESISTANCE — G. I. Leonard, Pasadena, Cal.
753,722.—FISH CLEANING MACHINE — Manula & Carlson, Astoria, Or.
753,602.—STAMP MILL—W. A. Merralls, S. F.
753,604.—MATRIX — W. G. Middleton, Phœnix, Ariz.
753,419.—BEVEL—W. V. Morrow, Los Angeles, Cal.
753,301.—LOCK NUT—F. Ohiols, Winnemucca, Nev.
753,427.—VALVE — Parker & Castleberg, Leavenworth, Wash.
753,737.—FRUIT DRIER — A. A. Quarnberg, Vancouver, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

READING STAND.—No. 752,977. Feb. 23, 1904. A. Howe, Olema, Cal. This invention consists of a frame or rack having turnable supports at the bottom upon which the book or paper may rest, extensions to either one or hoth sides removably attached, so as to regulate the width of the rack to the book or paper, a lamp or candle bracket with attachments by which it may be adjusted upon either side of the rack or its extensions for convenience, and means for supporting the rack in various positions and angles either hy specially prepared stands or hy means of attachment to beds, chairs or otber furniture.

SEAM RIPPERS.—No. 753,655. March 1, 1904. M. J. Bacon, San Francisco, Cal. This invention relates to improvements in devices for severing the thread or stitching by which the meeting surfaces of two parts of a fabric are united to form a seam. Its chief object is to provide a simple practical tool for rapidly accomplishing shis work and one which will require but little tkill and occasion but a minimum amount of fatigue on the part of the operator to manipulate

Whole No. 2278.—VOLUME LXXXVIII. Number 12. SAN FRANCISCO, CAL., SATURDAY, MARCH 19, 1904. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Economy in Construction.

In designing head frames the main objects to be attained are strength and economy of materials. In the ordinary construction the strength of timbers used is generally much greater than actually required, but the fault is not a bad one, perhaps. Better too strong and massive than too weak. An instance of what may be done in the way of economical construction is found at many of the zinc-lead mines of southwest Missouri, where the miners build a frame of 2x8 plank. The corners are formed of two planks spiked together at right angles, the edge of one plank overlapping the other. The base of the frame is square, the corners sloping inward to form a smaller square at the top, where the sheave is set on square timbers 6x8 inches—the smaller dimensions upward. Crossed 2x6 plank, spiked to the corners, give the necessary stiffness. Often a head frame like that here described is seen perched upon a high sub-structure, or trestle, of similarly light and apparently flimsy construction, yet, notwithstanding the insecure appearance of the frames of this design, thousands of tons of ore are hoisted from the mines, the load weighing 500 to 1000 pounds. It is claimed, and with reason, too, that expensive frames are usually inadvisable, as the ore deposits do not extend to great depth, not over 300 feet, and the most of them are within 150 feet of the surface, and as the deposits are exhausted with comparative frequency and operations must be resumed elsewhere, expensive head construction is not justified. The striking feature of the light, quickly built frames, is that "they do the work," which is all that could be desired of them. They are easily removable to another site, or if the timber is unsuited to this purpose of reconstruction, a portion of it at least can be used for braces and the balance for lagging, for shoveling boards, and in other uses about the mine.

In the mining regions of the Pacific and Rocky mountain States, however, the miners have little faith in frail constructions, and their head frames are noticeably massive and well constructed, and, as previously stated, the strength of materials used is usually much greater than is necessary. Thus, a sound yellow pine timber, 12x12 inches, 20 feet in length, supported horizontally at the ends, will sustain a weight in the middle of about twenty tons. Timbers of these dimensions are frequently seen in head frames, and, as they stand in a vertical position or one approaching the vertical, the stresses are in the nature of compression, rather than of transverse strain, to which the main members of a head frame are subjected. A frame composed of four massive timbers and tied together by braces and crossties to minimize vibration, is capable ordinarily of sustaining from 40 to 100 times the load it will ever be called upon to carry. In many frames of massive construction there can be discovered incongruities in construction, such, for instance, as a frame capable of sustaining 200 tons, with the back braces within the line of strain resulting from the lifting of the load, when the tendency of the pull of the engine is to overturn the entire structure; or a massive frame with weak and insufficient support for the sheave. One mine superintendent known to the writer built a heavy four-post frame, each post standing vertical, joined at the tops with caps and ties, and otherwise strengthened by diagonal braces; but the frame had no back-angle brace, the designer depending wholly upon the weight of the structure to hold it in place. It is in successful operation still, but a better frame might have been built with less than one-half the material.

Novel Style of Head Frame.

The accompanying engraving is that of a strong, well-built, four-post frame in El Dorado county, Cal., in which less material was used than is generally found in structures of this type. The two back members are also the braces which resist the thrust due to the pull of the engine and weight of the load. Instead of crossing angle pieces to stiffen the frame, sections of old mine cable have been employed for this purpose and the tensile strains are all taken by these. The pieces of cable are run through eye bolts, threaded for adjustment to the proper tension. The guides extend from the top of the frame vertically downward into the mine. A cross-head is in use, being secured by a clip about 6 feet above the bale of the bucket. This prevents the bucket from swinging in the shaft. A hole through the upper and lower cross-piece of the cross-head, through which the cable passes, allows the bucket to go to the bottom of the shaft when sinking, the cross-head resting upon lugs temporarily nailed to the guides. When the bucket is hoisted, a clip on the cable catches the cross-head and carries it above the bucket to the surface, as shown. The shaft is also supplied with a railing about the collar to prevent accident—a precaution too often neglected—and it also has a door, or apron, fixed on hinges and balanced by counterweight that buckets may be dumped without danger to men working below. The bucket is dumped by means of a trip rope and hook, the load falling on the inclined surface of the door from which it runs downward into the car placed to receive it. The entire construction is on scientific lines, is cheap, safe, common-sense and a type of the better class of woodeu head frame construction. When building, it was the intention, when sinking was discontinued, to build an ore bin in front of the frame.

THE several engineering societies having headquarters in New York City having decided to accept the offer of Andrew Carnegie to build a suitable building for the joint use of the societies, Mr. Carnegie has placed $1,500,000 at the disposal of the joint committee to be used for this purpose. The site chosen is between Fifth and Sixth avenues, and on West Thirty-ninth and West Fortieth streets. The societies benefited by this donation of the noted steel manufacturer are The American Institute of Mining Engineers, American Society of Mechanical Engineers, American Institute of Mechanical Engineers and the Engineers' Club of New York City.

A NOTABLE feature of the report of the Mine Commissioner of Colorado for the year 1903 is the large increase in zinc output, nearly $2,000,000, due to the success of the electro-magnetic separator. For years in the mining regions of the world the complex ores of lead, iron and copper, which also contained zinc, have remained to a great extent in the mines or have accumulated to the amount of hundreds of thousands of tons on the dumps throughout the mining regions, the zinc being an undesirable constituent of the ores upon which reduction works placed a penalty for excess over a stated percentage. The magnetic separator has changed this and ores containing zinc are now successfully treated, the zinc becoming a separate and valuable product. The more extensive introduction of machines of the class will not only largely increase the zinc output, but also make available a class of ore which heretofore has been avoided, as unremunerative and undesirable.

THE strike of great veins and mineral zones is merely an incident in their occurrence. The veins of the Rand in South Africa strike nearly east-west. The gold belt of California has a northwesterly trend, while numerous single veins and vein systems within it strike north-south, north-east and even east-west. The general course of mineral zones is usually observed to be parallel to the mountain system to the greater movements of which it owes its existence. Isolated veins or mineral zones will be found to have a strike due to local conditions. The dip as well as the strike is due to geological conditions which in no manner have any influence upon the amount or value of the ore deposition, although the dip may have a direct bearing upon the economy of ore extraction. There are those who have endeavored to formulate a theory which may be used to pre-determine the location of ore shoots, or the direction of their trend along the vein, but these are falacies so far as any rule thus far discovered can be applied.

Where Technical Education Counts.

In no pursuit in life is the technically educated young man afforded better opportunities to apply the knowledge gained in the University, or wherever he may have acquired it, than in the industry of mining and metallurgy. If two young men start for themselves upon a career in mine, mill or smelter, the one with several years' practical experience at one place under direction, the other with little or no practical experience, but with a technical education as a foundation, the race will be at first altogether in favor of the former; but not for long, for within a few months the advantages possessed by the latter, who is untrammeled by preconceived and possibly erroneous ideas, and has not fallen into a groove, as it were, is enabled to see clearly and to adapt some method, known to him in theory, to a condition which for the first time confronts him in practice. During the first year of the race the student gradually overtakes his more experienced neighbor, and during the second year the former has become the better and more valuable man. There are practical men who have had good opportunity at some mine, and they have mastered its every detail; but should it become necessary to go elsewhere, after years of service at the one place and with little or no knowledge of the conditions and methods at some other, the practical man, thrown now on his own resources, must go back and "learn it all over again" in a new and, to him, untried and unheard of way. He attempts the old and peculiar schemes used so successfully at home and finds to his surprise that they are inapplicable to the new condition. Here the young man with technical knowledge, but with fewer years of experience, forges ahead. He promptly recognizes a condition of which he has heard or read, and he knows the remedy to apply with the best chance for success. Should the first attempt fail, he tries another method, for he is versatile and is not limited to the one method known only to those whose experience has confined them to the rut. In metallurgy particularly is this true, for the diversity of ores is much greater than the peculiarities of mines. If a man once learns the principles of mining and learns them properly he can apply this knowledge anywhere in the world, but the millman and smelter requires a more diversified knowledge than the man who removes the ore from the vein or deposit. The miner can take out the ore, even if he does not do it in the most practical, up-to-date and economical manner. His shortcomings may be overlooked by the manager or owner, but the millman is expected to recover the value from the ore sent to the mill, and if he is unable to do it he must step aside to make room for some one who can. If ores were treated in the same manner everywhere there would be no difficulty and all millmen would be good men.

The Reward of Optimism.

In many oil fields a common experience has shown that often the early operators were too much inclined to discount the probability of a wider extent of the oil-yielding formation than that developed, and the known limits have been defined by well-known bore holes for long periods of time. Later others, either more optimistic or less experienced, have sunk a well far beyond the recognized limit of the field and "struck oil." At once the value of the find is appreciated and a renewed impetus is given the industry in that direction. An instance in point is the recent striking of oil in a bore hole west of the village of Coalinga, Cal., where the oil stratum was cut at 1100 feet from the surface, the well having a natural flow. This is said to extend the known limits of this field 1½ mile to the southward from where it had been established. Oil men, like miners, are sometimes controlled by prejudice, and nothing places a greater restriction upon the development of a section than the notion that there is nothing there worth seeking for.

Another instance is noted in northern Santa Barbara county, Cal., where a company had a good flow of 20° oil at a depth of 2000 feet. Another company operating in the vicinity struck what was evidently the same sand at about the same depth, but concluded to bore deeper in hope of finding improved conditions, and as a result at 3000 feet they struck a flowing well of 28° oil. There are cases where the geological conditions are such that it is known to be useless to search in a certain region for some particular mineral, such as beds of coal or oil sands in granite or greenstone schist, but often there exists an uncertainty, and it is then that the element of uncertainty should suggest that a trial at least be made to determine what conditions do exist.

Difficulties in Cyaniding.

The chemistry of the cyanide process is well understood by those who have made it a specialty, although there still remain differences of opinion on minor points. If an ore is amenable to the process the proposition is worked out along a line of well-known experiments, both in the laboratory and in the plant. In some instances the dissolution of the gold is accelerated by the addition of certain chemicals, or by the introduction of air. Some of these ideas have been the subjects of patent. On the whole the difficulties of dissolving the gold and securing a satisfactory extraction are not numerous, but the mechanical manipulation of the various materials handled still presents unsolved problems. The great diversity of practice and the variable results obtained are evidence of this. At one plant impalpable slimes are treated satisfactorily, at another little success results upon what is assumed to be similar material. Agitation, either mechanically or by means of compressed air, does not give equally satisfactory results at different plants often in the same region. One operator mixes slimes and sands and announces success; another tries the scheme and declares it a failure. Numerous cyanide operators declare that agitation and filter pressing are means to the attainment of success in treatment of slimes. Others maintain that flocculation of the slimes and decantation of the clarified solution are the only pathway to the desired end. Some favor dry crushing, others say it is unsatisfactory and more expensive than wet crushing. There are numerous other subjects of contention and some of uncertainty. Still the process goes on and is improved from time to time, though these betterments are mostly of a mechanical kind. The present practice, as compared with that of the early years of cyaniding, cause one to wonder that we could have been so stupid, but the cyanide process is not unlike other processes of the past and newer processes to come. Each successful process in ore treatment is the result of increasing knowledge due to scientific experiment and intelligent application of the result to the operation of the plant on a commercial scale. All of these variations in the operation of the process merely represent the widely varying condition found in the ores treated, as well as the individual experience of the operators, and also, possibly, some prejudice. The principal difficulty in the process is that of precipitation. If the gold in a solution does not precipitate readily the cyanide operator finds more difficulties to overcome than are found in all of the balance of the process. Zinc in various forms, charcoal and electricity each are used in the process at various places, but the cyanide expert is still in search of a better method.

THE mining laws of the United States are not without uniformity, and Land Department decisions, while having force as precedents, do not supersede the statutory laws, nor the decision of the courts. States, and even mining districts, may make laws governing the acquisition and holding of mining claims, but these laws are void if in conflict with the federal statutes. It would, no doubt, be an advantage to have uniformity of law throughout the mining States, instead of a variety of laws representing the opinions of various powers in the several States, and in this respect Mexican mining laws are superior to those of the United States, as they are uniform throughout that republic, and they embody many things which might be adopted in the United States to the advantage of the mining country throughout the West, not excepting the square location and abolishment of the extralateral right.

CONCENTRATES.

THE mineral from Pollasky, Cal., is augite andesite. It contains no valuable mineral, though there is in it abundant magnetite in grains.

✣✣✣✣

IN AUSTRALIA the wood of the red gum, a variety of eucalyptus, is used for battery guides, and for this purpose is said to be superior to any other wood thus far tried for that purpose.

✣✣✣✣

LARGE spur wheels should be provided with a metal sheeting or an iron rail to protect workmen who are obliged to pass. Such preventives of accident are inexpensive and worth far more than they cost.

✣✣✣✣

THE iron mines of Tepustette are on the peninsula of Lower California, near San Quentin. The ore is chiefly hematite and is high grade in iron. No large amount of development has been done. The outcrop is large. The deposit is near the sea.

✣✣✣✣

BITUMINOUS materials are soluble in chloroform, turpentine and carbon di-sulphide, and not in water. By this means the presence of bituminous material may be distinguished from organic substances which it somewhat resembles in appearance.

✣✣✣✣

A CONVENIENT method of determining whether crude petroleum contains sand or not is to pour the oil on one end of a sheet of glass, and holding it at an angle allow the oil to run over the plate, when grains of sand, if present, will be plainly visible.

✣✣✣✣

THE mineral specimens from Forest Hill, Cal., are: No. 1, serpentine; No. 2, also serpentine, but sheared (essentially talc schist); No. 3, diorite, partly altered; No. 4 is schist altered from No. 3. The serpentine may contain gold, but none is visible in the specimen.

✣✣✣✣

THE cheapest engineer is not always he who receives the least pay, but he who understands his craft and knows how to economize on fuel and steam and who gives the machinery in his charge the proper attention. The cheap man may prove a most expensive one.

✣✣✣✣

THE mineral specimen said to come from Siam is cassiterite, the oxide of tin. The specimen appears to be nearly pure cassiterite, there being only a little iron oxide present. In this specimen the mineral occurs as an aggregate of crystals, many of which are translucent.

✣✣✣✣

THE turbine wheel may often be employed with satisfactory results where a large volume of water is available under comparatively low head, and utilized to run mills and other machinery where a high head, sufficient to supply the necessary power by means of an impact wheel, is unattainable.

✣✣✣✣

FROST AND ICE may usually be removed from pipes by pouring alcohol in the pipe. Pipes frequently choke up with ice at the point of entering the ground, due to freezing of moisture within the pipe. If water pipes be well wrapped with gunny sacks they will not freeze except in extremely cold weather.

✣✣✣✣

THE United States census for 1900 showed that about 75,000 men were occupied in the mining and reduction of gold, silver, copper, lead and zinc ores, and that the value of the output averaged $1800 for each individual thus employed. This was the highest per capita output of any of the industries, including agriculture, forestry and manufacturing.

✣✣✣✣

OIL was discovered in eastern Wyoming in 1875, and was used as a lubricant by the Homestake mine at Lead City, South Dakota, as early as 1879. Salt was also manufactured in Weston county, Wyoming, near Jenny's stockade in 1879–'80, which was hauled to Galena, in the Black Hills, for use in chloridizing the silver ores of the Sitting Bull mine.

✣✣✣✣

SILVER CHLORIDE occurs in ores in the form of minute scales, in sheets and veinlets, and in masses up to those which weigh several pounds. Some of the Fryer Hill mines at Leadville, Colo., produced masses of horn silver (chloride), upwards of a foot in diameter, and the mines of White Pine, Nev., and some of those of Arizona and Mexico, also produced large masses.

✣✣✣✣

IN underground mining, machine drills are generally mounted on bars placed either horizontally or vertically, though occasionally the tripod is used in setting up the machine. The tripod is used more in Butte, Mont., mines than in any other camp in the West. The tripod is a necessity in quarrying and it may be used to advantage in some stopes underground.

✣✣✣✣

THE rock specimen from Santa Clara county, Cal., is sandstone and consists of both angular and rounded grains of quartz. The cementing material is clay and silica. It may be employed as a structural material in low buildings. The rock is too coarse and incoherent to withstand very great pressure. It should be placed in such position as to bring the pressure perpendicular to the planes of bedding.

✣✣✣✣

IF the shaft "squeaks," stop the mill and relieve the shaft, and rebabbit the boxes, if necessary, and, if the shaft is out of line, rebabbitting is generally required. If the covers have been removed from the cam shaft boxes, at least cover the bearings with canvas aprons to keep out dust and grit. A bearing is not improved nor is friction lessened by allowing grit to fall upon the revolving shaft, to be carried into the bearings.

✣✣✣✣

SOME ores containing copper in the form of carbonate and silicate (chrysocolla) and fine gold have been successfully treated by the cyanide process, by first leaching out the copper with a dilute solution of sulphuric acid, and subsequently treating the pulp with cyanide solutions. The success of this operation depends to a great extent upon getting rid of the copper solution and free acid, which must be accomplished by means of wash water, and, in some instances, by neutralizing the remaining acid by means of alkali.

✣✣✣✣

THERE is a distinction between the "weight" of water in pipes and the "pressure" of water in pipes. Thus, a pipe 10 inches in diameter and 100 feet in length will contain a volume of water weighing 3404.75 pounds. If lying horizontally and closed at both ends, there will practically be no pressure on the pipe. If the pipe be lifted up and stood vertically, then the pressure at the bottom of the column will be 43.35 + pounds per square inch, or a total pressure at that end of the pipe of 3404.75 pounds, while the pressure at the top will be nothing.

✣✣✣✣

ATMOSPHERIC PRESSURE at the sea level is nearly 15 pounds per square inch. At 5000 feet altitude it is about 12.27 pounds per square inch; at 10,000 feet about 10 pounds per square inch, and at 15,000 feet but 8.33 pounds per square inch. The atmospheric pressure may be found approximately by multiplying the barometric reading in inches by 0.4908. The atmospheric pressure is not diminished in direct proportion to the altitude. At sea level the first inch increase in pressure represents 917 feet. As altitude is gained it requires an increasingly greater height to reduce pressure 1 inch.

✣✣✣✣

PIPES made to convey water under pressure are required to be stronger than those conveying air under the same pressure, for the reason that air, being elastic, is not subject to shock like that caused by the sudden stoppage of water when in motion, flowing through a pipe, and which is known as "water hammer." Air pipe must have equal strength throughout as the pressure is practically equal on every square inch of its inner surface. In the case of a water line along an uneven surface, the strength of the pipe must be proportional to the amount of pressure it will be required to stand, which is determined by the height of the column of water.

✣✣✣✣

BY "free air" is meant the air as it exists in nature, its density varying with the altitude above or below sea level. When compressed mechanically, the pressure increases as the volume of air, as it originally existed, is diminished. At 60 pounds pressure a cubic foot of air is equal to 5.08 cubic feet of free air. That is, if 5.08 cubic feet of free air be compressed to the space of 1 cubic foot, its tendency to expand will be equal to a pressure of 60 pounds upon each square inch of the foot cube. At 100 pounds pressure a cubic foot of compressed air is equal to 7.802 cubic feet of free air. The efficiency of the pressure is dependent upon the elevation at which the compressor runs.

✣✣✣✣

ANTIMONY is found in metallic state, but is usually combined with sulphur as the sulphide stibnite. The metal is obtained from the sulphide by melting it with wrought iron scrap, when the sulphur combines with the iron, freeing the antimony. Another method of reduction is by roasting the ore, burning the sulphur to dioxide, the antimony being converted to oxide, from which it is reduced to metal by mixing with charcoal and fusing the mixture. The metal is poured into a mould, when, upon cooling, beneath the slag, the metal crystallizing first, it assumes a peculiar fern-shaped surface, and this is evidence by means of which purity may be judged by those having experience.

✣✣✣✣

IN the construction of small two-post head frames it is sometimes economy to frame the opposite sides and erect them separately by means of a "gin" pole, or to erect the two uprights with cap and tie, and after guying them securely, to put up the angle braces. In an instance in Amador county, Cal., the entire frame was joined and bolted together on the ground, a post, sill and angle brace being first joined for one side, and a similar set for the opposite side. These were then turned on edge, the posts lying on the ground, and then joined by cap and tie, and the entire frame then tilted backward, bringing the sills in place upon the ground, when it was forced into its exact place at the shaft.

✣✣✣✣

THE cost of monthly repairs on machine drills depends upon many things. If the drills are new and in good condition, the repairs naturally should be far below that required on old well-worn machines. If high pressure is employed—100 pounds, instead of 60 or 65 pounds—the wear and tear will be greater, but so will the amount of work. Machines do not require repairs proportional to the hardness of the ground. Much depends upon the man running the machine. If he fails to feed up properly, he runs the risk of breaking the front head. If he feeds too fast, he accomplishes loss work. Beating the drill, the chuck or the machine with a hammer is bad practice—particularly the latter—though machines sometimes show evidence that this is done.

✣✣✣✣

WHERE air is to be introduced under the charge of ore in a cyanide tank, the futility of placing the perforated pipes beneath the canvas filter of the false bottom has been proven. When this is done the air invariably seeks outlet around the edges of the false bottom, bubbling up around the inner periphery of the tank. Where air is introduced through perforated pipes to supply oxygen to the charge, experiment has shown that if air is pumped in for twenty to thirty minutes every two hours the result is as effective as if pumped in continuously. By arranging a system of valves along the pipe line running to the tanks, this may be controlled. The result of following the above suggestion is that a smaller compressor may be employed and a larger number of tanks aerated by the intermittent system.

✣✣✣✣

IN roasting ores, if too high a heat be employed, the metallic particles will have a tendency to agglutinate, which would, in most cases, unfit the ore for further treatment. The cost of treating ores by the chlorination process will depend first upon situation, which will have a bearing upon cost of fuel, supplies and labor; second, character of ore treated, whether easily roasted or treated with difficulty; third, the process employed, of which there are several, each having modifications. The barrel chlorination process is probably the most satisfactory, as it is continuous and treats a wide range of ores successfully when manipulated by experienced hands. In some of the southern States the treatment of gold-bearing sulphides is done at a cost of less than $5 per ton, while in the rest the cost is from 50% to 100% greater, and in some instances more.

✣✣✣✣

THE cyanide process cannot be applied successfully to the recovery of coarse gold from ores or placers. Where an ore contains both fine and coarse gold, amalgamation should be tried, and if the tailings from the stamp mill still contain values sufficient to justify the treatment, cyanide may be found serviceable in extracting a large percentage of the remaining gold. In some mills the ore is crushed with the cyanide solution in the battery, but where this is done amalgamation on outside copper plates is impossible, as cyanide of potassium renders amalgamated plates very hard and brittle and unfit for the purpose of holding gold. To be good amalgamators the copper plates must be soft and as porous as possible. Plates spoiled by the use of too much cyanide in dressing, or by the flowing over them of large amounts of cyanide solution, should be annealed and replated with silver, when they will be as good as before.

✣✣✣✣

IT is doubtful if the courts would accept work done to maintain a ditch and flume line originally built to supply power to a mine and mill, but which are now idle, as annual assessment work on the mine, and this doubt is enhanced where a portion of the water is sold to others for domestic or other purposes while the mine remains idle. The statute clearly requires that assessment work upon unpatented mining claims, whether upon the claim or on other land outside the boundaries of the claim, must be of such a nature as to actually promote the extraction of mineral from the claim. The original cost of the ditch and flume might be charged as assessment work—that is, $100 of such cost for each claim for the year only when the work was performed—but money expended for a survey for such ditch line would not be accepted as money expended for the benefit of the claim.

✣✣✣✣

NO EVIDENCE has ever been produced to indicate that gold nuggets "grow." When a mass of gold, great or small, is freed from its matrix and is carried by drainage water into the neighboring gulch, it at once begins to lose weight by reason of abrasion to which it is subjected among the sand, gravel and cobbles which move along with it. The greater the distance a nugget travels the more will it be worn and battered by the rocks. In the first few yards of its travel it may still retain many angular faces and ragged edges, but, moving farther and farther from its source, the amount of drainage water is likely to increase, with the result that larger and still larger rock masses move with the gold, or over it, should it chance to become lodged in a crevice, and the scouring action constantly reduces it in size, and pounds it out of all semblance of its former shape. Often nuggets are found having quartz and iron within the mass. These particles have undoubtedly been caught by the folding over them of a portion of the nugget, which is quite possible in the case of leaf-like or filiform masses of gold, and as the nugget is abraded and pounded by the rocks the evidence of the metal having been folded, as it were, becomes obscure and may be destroyed entirely. Doubtless by this process of abrasion good-sized nuggets have been entirely worn away, and thus lost to the miner. From the moment of its release from the vein the golden mass grows smaller and never adds a particle to its weight. Dental gold is a mass of specially prepared porous metal, and gold in this form does not exist in nature. In any other form gold cannot be built up to a larger mass by pounding.

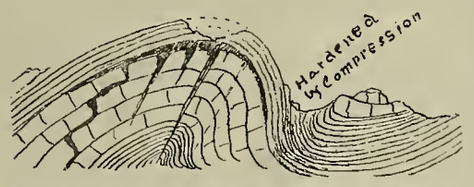
Ore in Anticlinals, as at Bendigo, Australia, and Tombstone, Arizona.

Written for the MINING AND SCIENTIFIC PRESS by ARTHUR LAKES.

The descriptions of the anticlinal and synclinal form and occurrence of ore deposits in the saddle reefs and "inverted saddles" of Bendigo, Australia, by T. A. Rickard and W. H. Cundy, are of much interest to those who have worked among ore deposits in regions of folded slates, schists, or other ore-bearing sedimeutaries. It has seemed to me that the occurrence of ore bodies on the tops of anticlines and their general absence in the synclines may have some analogy with the occurrence of oil, gas, and water iu the oil fields. Anticliues, as is well known, are the favorite habitats of oil and gas, the theory being that compression of strata has forced the oil and gas on top of the water into the summit of the arch, the propelling agent being the hydrostatic pressure of the water, back of the oil. It is generally supposed that by lateral pressure, on folding, a cavity is formed on top of the arch (as in folding sheets of paper) where oil and gas find a ready receptacle. It is also recognized that anticlines open in cracks or faults at or uear the summit of the arch. In an anticline, too, there is commonly a short, steep side and a "long leg" or gently sloping side. The pressure has been exerted from the steep side, and water, oil and gas have been forced up mainly on or from that side to the summit of the arch and collected there, either in the arch cavity or in the fault fissures. If the water pressure back of

Toughnut Anticline, Tombstone, Arizona.

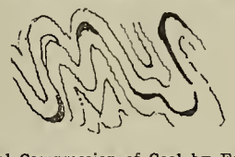
the oil is very great it may even force those lighter materials over the arch and down the long leg. While the anticlinal is the seat of the oil and gas, the synclinal or trough is commonly destitute of these, but often abounds in water. Now, in place of oil and gas, if we substitute metallic vein solutions forced upwards by hot waters and steam in the anticlinal slates and schists, and depositing or precipitating there both ore aud vein stuff, we may form an idea why the anticlines of saddle reef formations are so



Folds Showing Ore in Anticline and None in Syncline.

liable to carry lenses of quartz and ore, and why the correspondiug synclinal basins, or "inverted saddles," are so geuerally barren, as also why loops as well as fracture zones occurring at the tops of these saddles and on the sides are filled with quartz and ore.

The general absence of oil as well as ore in the synclines may be due, especially in pliable strata, like shales, to a compacting by pressure in the re-



Unequal Compression of Coal by Folding.

entraut curve of the fold or the general compacting by pressure of strata crushed and squeezed between two parallel folds preventing free circulation of liquids at that point.

It has been observed that the strata between anticlines is so pressure hardened that by erosion, synclines often form hills, and anticlines, valleys. Synclines, however, may occasionally carry oil or ore bodies, as observed in the former case in the oil region of Florence, Colorado, and in the latter in the "inverted saddles" of Bendigo, as described by Cundy.

In some cases bedded veins have been folded up with the strata iuto anticlines or saddles, but in those which we have in view (in contorted schists), the ore bodies entered the cavities subsequent to or at most contemporaneously with the folding of the rocks. That great compressive force was exerted in forming these folds, and that cavities, loops or arched zones of weakness were produced near their summit, is shown by Geikie, who says:

"In strata which have been intensely crumpled the same bed is reduced to the smallest thickness in the arms of the folds, but swells out at the bends as if squeezed, laterally, into loops. Into these loops soft substances, like coal, having least resistance, are sometimes squeezed or thrust."

In cases of segregative veins, formed contemporaneously with the folding movement when the strata was in a plastic or semi-plastic condition, we can understand how a soft, gelatinous quartz might similarly be squeezed, forced, or molded, or ooze into these loops.

Besides the noted cases of the saddle reefs of Australia, we have a good example of these phenomena at Tombstone, Arizona, as lately described as follows by A. Church, in Trans. A. I. M. E., XXIX, p. 511:

"Twenty years ago, Tombstone was the most noted mining camp in Arizona. It represented a combination of fissure veins and bedded deposits in relations which were most puzzling and impossible to make out until the extensive development of the mines permitted every detail to be observed. The sedimentary beds associated with the ore deposits are Lower Carboniferous limestones, shales and quartzites, folded and traversed by igneous dikes.

In the Toughnut claim the outcrops lie in an irregular horseshoe which has a deformation near the point of the curve, suggesting pressure against a big eruptive mass of grano-diorite. The sedimentaries are especially rich in dikes at their contact with the grano-diorite. The grano-diorite shows a fault face against which folds of the strata have been developed.

The structural conditions show that the ores from some underlying source ascended through fissures to be deposited in the cavity and in the strata which had been prepared by folding for the entrance of solutions. The rocks owe their ores to the combined results of pressure, folding and fissuring.

The folding is in two directions, producing anticlinals with axes varying in direction.

Monoclinic flexures also lie across the anticlinals. They are usually of gentle slope, while the anticlinals are highly compressed and sometimes faulted.

The bedded deposits lie in the anticlinals, sometimes on the flank, sometimes in the apex, but the synclinals are barren. The monoclines have not limited the deposition of ore.

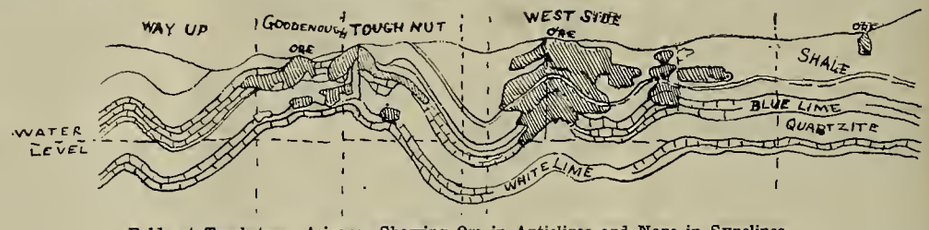
The compound surface produced in any stratum by these cross folds was a controlling factor in the distribution of ore, which is found in all shapes from long, narrow tongues to broad sheets. The simple anticlinal structure of the "saddles" is disturbed by the monoclinals resulting in the formation of numerous vertical crevices, sometimes receiving enough ore to join two overlying bodies together. The ore body may occupy the flank of an anticlinal which dips towards the spectator. Two lines of vertical fissures lie across the system of anticlinals, in both of which are important ore deposits and mines. The largest ore bodies of the fissures are found within the lines of the anticlinals whether the fissures reach the limestones which contain the bedded ore deposits or are still in the overlying shale.

The water level in the Contention and Grand Central mines is 150 feet above the blue limestone contaiuing the highest ore bodies of the Toughnut series, but the influence of the anticlinals upon the deposition of ore in the fissures is as marked in the overlying shales through which the fissures pass in these upper levels as in the limestones of the bedded deposits.

The second result of dynamic action was the production of vertical veins or "compression fissures." In the West Side mine the principal ore body of the fissure is confined to a strongly compressed anticlinal 450 feet long. This fold is succeeded north by a broad, barren synclinal and on the south by a narrow synclinal aud a gently rising anticlinal. The fissure passes through shale for the first 200 feet of its depth and there is a small ore body within the synclinal in the shale.

There are three parallel fissures within a width of 400 feet at the West Side mine, two of which yield ore. The walls do not indicate faulting. The ore bodies of the Goodenough and Toughnut are also exclusively anticlinal. The synclinals are here also barren. The steeper and sharper the anticlinal the greater the size and better the grade of ore. The Grand Central and Contention mines show very clearly the combination of inclined anticlinal deposits and a vertical vein. The two classes of deposits dip in opposite directions. The compression fissures have been the most prominent factors in the introduction of ore as the anticlinals have been in its distribution. Nowhere is ore found in the shale except in the fissures in it. This shows the controlling necessity of crevices as a preparation for ore. Torsion cracks occur in the limestone and quartzites. The igneous dikes seem to have had only an indirect influence on the ore deposition. The Tombstone ores are the product of replacement both in the crevices, fissures and anticlinals. Anticlinal faulting preceded the deposition of ore and no ore bodies were faulted after their deposition.

Roughly speaking, about half the gold and silver produced in Tombstone has been taken from the upper shales, about a third from the blue limestone and the white limestone, and the remainder from the "Lucky Cuss" limestone. The mines of this old and well known camp are being revived and the anticlinals searched for, and followed on scientific geological principles.



Folds at Tombstone, Arizona, Showing Ore in Anticlines and None in Synclines.

The Genesis and Character of Ore Deposits.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

The most important matter in the operation of a mine, aside from the mechanical problems involved, is a study of the varied phenomena which accompany the geuesis or formatiou of the vein or deposit as the work of exploration proceeds. This class of observation has been reduced to a science and is known as mining geology, a term employed in contra-distinction to structural or stratigraphical geology.

Ore bodies have many features peculiar to themselves, and may be studied within themselves independently of any extraneous phenomena. The study of ore deposits, with a view to classifying them, has received much attention, and the abundant literature on this interesting and important subject indicates that there are still different opinions entertained on various matters in this connection by those considered high in authority on the subject of mining geology. Mineral deposits and veins have been described by various geologists in terms calculated to convey an idea of their characteristics. Thus there are fissure veins, bedded veins, contact veins, mineral zones and numerous other forms of mineral deposit. The occurrence of a vein always conceives a pre-existing cavity, or a zone of fracture or dissision, within which there were innumerable interstitial spaces through which mineral solutions might pass more readily than through the pores of a solid rock. When mineral solutions are passing through such veins, spaces, or zones of fracture, certain chemical reactions are supposed to take place, and as a result the various minerals held in solution are precipitated and deposited usually, if not always, originally as sulphide. Under the varying changes of temperature and pressure, as the surface of the earth is approached, various minerals are deposited independently of others which may be present. It is thought that zinc is one of the first minerals to be differentiated from such solutions arising from great depth through the fissures or zones of dissision, and deposited on the walls of the fissure or in the spaces of dissision. At higher levels, copper, irou and lead sulphides are deposited, though there is usually found more or less of each kind of mineral throughout the entire depth of the fissure. It is a well-known fact, however, that iu many veins zinc is unknown until considerable depth has been reached. The disappearance of some minerals from the upper portion of veins is due in many cases to secondary causes, and has been accomplished by descending currents of cold water and not hot ascending solutions. The processes of ore deposition, together with its possibilities, are most fully appreciated by those who have had an opportunity to visit geysers, boiling sulphur and hot mud springs. There are numerous places in volcanic regions where acres are essentially a seething cauldron of boiling water and mud. Great volumes of steam aud sulphurous gases fill the air, while under foot may be heard the murmur and threatening rumble of the escaping steam and scalding water. In some instances these hot springs, sulphur deposits and geysers, occur aloug the line of a fault, as may be seen by the relative position of the surrounding beds of rock—usually of volcanic origin. This is the case at some of the hot springs and solfatara in the vicinity of Lassen peak, Cal., where in Hot Spring valley, on Warner creek, this type of volcanic action is still in strong evidence. About

many of the vents sulphur is being deposited and about others iron oxide, while at others near at hand neither iron nor sulphur deposit is visible. The hard andesitic rocks in the vicinity of the springs are found altered to kaolin, or silica, and in some places both occur, as well as calcium carbonate. In some of these places boulders of comparatively fresh rock have within recent years rolled down the hillside and have lodged in the immediate vicinity of one of these sulphur-steam vents. The result is invariably that the rock most directly exposed to the action of the hot sulphurous gases is already kaolinized to a depth of an inch or more, showing how rapid is the decomposition of massive rock under such conditions of heat and moisture in the presence of sulphurous gas. Were it possible to drain this fault fissure of its scalding solutions and divert the steam and other vapors elsewhere that the fissure might be exposed, it would, without doubt, be found to resemble in a marked degree a mineral vein in many respects. The hard andesite forming the walls of the fissure or fissured zone would be found altered to a mixture of kaolin, calcium carbonate and silica, and doubtless iron sulphide would be found deposited in the fissures and in the clay walls. Whether other minerals would be discovered it is impossible to say. At Steamboat Springs, about 6 miles from Virginia City, Nev., which somewhat resembles that above described, G. F. Becker reports an essentially similar condition, but here careful and exhaustive chemical analyses have demonstrated that at Steamboat Springs are now being deposited "gold in metallic condition, sulphides of arsenic, antimony and mercury, sulphides or sulphosalts of silver, lead, copper and zinc, iron oxide and possibly, also, iron sulphides; and manganese, nickel and cobalt compounds, beside a variety of earthy minerals. The sulphides which are most abundant in the deposits are found in solution in the water itself, while the remaining metallic compounds occur in deposits from springs now active or which have been active within a few years."

The occurrence of these minerals in active solfatara indicate in an unmistakable manner the origin of a certain class of mineral deposits—those occurring in fissured zones, in massive rocks, and it may also be considered as an indication of the possible manner of occurrence of all mineral veins. There are veins in which the walls have been but little altered and in which the vein filling is chiefly quartz, with the several more commonly occurring sulphides of the base metals, together with native gold, silver ores and tellurides of gold and silver. Many veins in slates, granites and schists are types of this character. It may be that these veins were formed by deposition from cold solutions. No evidence of unusual heat is noticeable in mines of this class, while in veins like the Comstock, which are of the former type, great heat of the workings and of the water are characteristic, and indicate the probable genesis of the ore deposits. It is unlikely that all ore deposits, whether occupying fissures, zones of dissision, or occurring as the result of metasomatic replacement of soluble mineral in certain rocks (as lead and zinc deposits in limestone), are formed by the same processes. The conditions as observed in ore deposits indicate that they are formed in various ways. Some of the most noted and profitable deposits are the result of secondary processes and not due directly to the primary deposition of mineral in the veins, or zones of mineralization. Among this latter are certain copper deposits where the normal deposit is composed wholly of iron sulphide, with a small amount of copper-iron sulphide sparingly scattered through a large rock mass. The decomposition of this ore, due to oxidation, results in the leaching out of the greater part of the more soluble copper which is carried downward by percolating surface waters, and redeposited in convenient localities in those places best fitted to receive it, generally zones of fracture and crushing, until the leaching out of the small copper content of a large rock mass results in the formation of rich concentrated deposits of ore of relatively small mass. If 1% of copper were leached by atmospheric or other agencies, such as oxidation due to drainage, from a million tons of slightly mineralized rock, and the copper were concentrated in a zone of crushing of only one twenty-fifth the mass of the rocks from which it was leached, the result would be an ore body of about 50,000 tons containing 20% of copper. If the size of the ore body were smaller the grade of ore would be correspondingly richer. This is known as secondary enrichment of ore bodies, and is particularly noticeable in copper deposits. Among the ores due to this secondary enrichment are azurite and malachite, the carbonates of copper; cuprite and the black oxides; and at deeper levels chalcocite (copper glance), chalcostilbite, tetrahedrite and other complex ores of copper, often rich in silver, and sometimes also in gold.

As a rule the miner is less interested in the mineralogical characteristics of his ore deposit, except as to its richness, than he is in its size and form, and the economy of its removal and reduction into coin. Unquestionably the form, size and position of an ore deposit are most important considerations in its equipment, development and eventual removal. The various forms of ore deposits have been classified partly according to their supposed genesis, and partly in accordance with their form or manner of occurrence. There have been numerous writers on this interesting subject, both in Europe and America, and in many respects these authorities agree, but in minor details there is much variance.

J. F. Kemp, in his ore deposits, has adopted the following classification which has been accepted by many geologists. Briefly, this classification is as follows:

I. Deposits of igneous origin. Extremely basic developments of fused magma. Peridotite forming iron ore at Cumberland. R. I.; titaniferous magnetite, Jacupiranga, Brazil; iron ores in numerous gabbros; nickel-bearing pyrrhotite, chromite in serpentine, etc.

II. Deposited from solution. Surface precipitations forming beds, due to:

1. Oxidation—bog iron ores.
2. Sulphurous exhalations from decaying organicmatter—pyrite.
3. Reduction by carbonaceous, organic matter—pyrite from ferrous sulphate.
4. Evaporation, cooling, loss of pressure in hot springs deposits, as at Steamboat Springs, Nev.
5. Secretions of living organisms—iron ores by Algæ.

Disseminations in particular beds or sheets, due to:

1. Selective porosity, as silver ores in porous rhyolite; in sandstones, and copper in conglomerate.
2. Selective precipitation by calcareous matter; the telluride gold ores of the Black Hills, S. D.

Filling joints caused by cooling or drying; veins in Mississippi valley.

Occupying chambers or caves as at Cave mine, Utah. (Also at Santa Eulalia, Mexico).

Occupying collapsed brecciated beds, caused by solution and removal of support. Occupying cracks at bends of monoclines, anticlinal summits, synclinal troughs, often with replacement of walls.

Occupying shear-zoues or dynamically crushed strips along faults, as at Butte, Mont.

True veins occupying exteuded fissures, often with lateral enlargements (vein chambers).

Occupying volcanic necks, in agglomerates, as at the Bassic mine, near Rosita, Colo.

Replacements iu troughs, as the hematites of Lake Superior.

Contact deposits, where igneous rocks always form one wall.

Segregations formed in the alteration of igneous rocks (chromite in serpentine).

Deposited from suspension, as residual deposits. Metal bearing sands and gravels (beach sands placers, ancient and recent).

Residual concentrates left by weathering of the matrix.

The above are practically all of the various forms of ore deposit that have been recognized, and a knowledge of their occurrence is essential to the best methods of development and extraction. Many miners lacking this knowledge have run lengthy and expensive tunnels to reach flat beds of ore lying at a higher altitude on the mountain sides, which were never cut by the tunnel, and in some instances shafts have been sunk through such beds and extensive exploration carried on below without encountering ore of value, as was done at the Running Water, Wyo., silver-bearing quartzites.

Every prospector and miner who is workiug for himself, as well as those who are employed by others, should have some knowledge of the elements of mining geology, for it may save the one possessing it great unnecessary expense, and may bring success where without it failure only may result.

Some Laboratory Work and Cyaniding.

To the Editor:—There are some slight inaccuracies in J. J. Macdonald's recent letter in your columns of the issue of March 12 to which I should like to call attention.

Of course, every well posted chemist ought to know "there is more alkali in NaOH than in $CaCl_2$," the latter (calcium chloride) being practically a neutral salt, but chloride of lime, while it consists essentially of calcium hypochlorite and chloride ($Ca(OCl)_2$ $CaCl_2$), often contains a large proportion of calcium oxide, some of the lime used in its manufacture having failed to absorb chlorine. Further, in actual practice it does not always increase the consumption of KCy, and it has been used in some instances with advantage, even without a subsequent wash.

Also the substance which sometimes coats zinc shavings is not zinc potassic cyanide (K_2ZnCy_4), which is a readily soluble salt. In cases which have come to the writer's notice, the coating has consisted of basic zinc cyanide—a mixture of ZnO and $ZnCy_2$—which will dissolve in a solution of free potassium cyanide, or in a moderately strong solution of caustic potash.

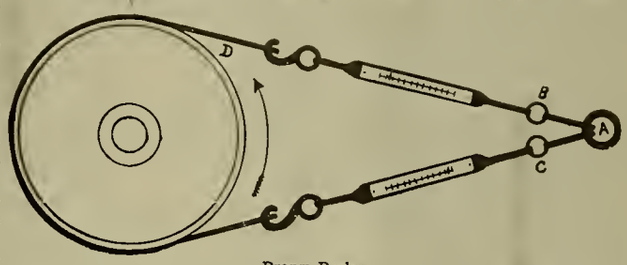
Berkeley, Cal.

The Russian Government has authorized the establishment of two branch banks in the Caucasus, for the special purpose of making advances on ore shipments and regulating the sale of manganese ores.

To Determine the Horse Power of Gas Engines.

Written for the Mining and Scientific Press by Wm. H. Kritzer.

There is no method by which the exact power of a gas, gasoline or oil engine may be determined, except by measurements with a "Prony brake," which gives the actual or available horse power at the engine pulley, at any given speed and any given brake load, this brake horse power being less than the corresponding indicated horse power required to drive the engine itself at the given speed.



Prony Brake.

Take two spring scales and a piece of belting. Hook a scale at each end of the belt, the latter is then passed around the driving pulley.

Next fasten the thumb ring of each scale by a cord to a suitable piece of wood A. After the engine is started by means of the lever A, both scales are drawn back until the friction of the belt slows the engine to its proper working speed.

The readiug of the scale C being the least, it is subtracted from that on the larger, B, which will give the net pull in friction of the brake in pounds.

Next multiply the distance around the driving pulley in feet by this net pull, and we get the number of foot pounds per revolution. And if we multiply the number of foot pouuds per revolution by the number of turus per minute of the wheel we get tbe number of foot pounds the engine gives per minute.

As an illustration, suppose the reading of the scale B is 70 pounds and that of C 10 pounds, and the speed of the driving pulley is 500 revolutions a minute.

If the diameter of the driving pulley is 35 inches, its circumference will be $35 \times 3.1416 \div 12 = 9.163$ feet.

So the power of the engine would be $70 - 10 \cdot 60 \times 9.163 \times 500 = 274{,}890$ foot pounds a minute; and as 33,000 foot pouuds a minute is 1 H. P., the eugine would be giving $274{,}890 \div 33{,}000 = 8.33$ H. P.

In practice it is well to keep water ruuuing on the belt at D and have an assistaut iu makiug the test.

The approximate power of an engine can also be computed very much the same as a steam engine, i.e., the horse power formula being $\frac{P \times A \times L \times E}{33{,}000} =$ H. P., viz.: Mean effective pressure (P) $\times$ pistou area in square inches (A) $\times$ length of stroke in feet (L) $\times$ number of explosions per minute (E), and the result obtained $\div$ by 33,000.

In the ordinary single cylinder engine known as the four-cycle type, the number of explosions can never exceed one-half the number of revolutions, while in the two-cycle type there can be an explosion every revolution.

After deducting all losses, the four and two-cycle types have been fouud to give nearly the same power for the same size, the average useful pressure being about sixty-six pounds per square inch in a well designed four-cycle engine; aud in the two-cycle approximately one-half of this.

Notes on the Construction of Mine Bulkheads.*

Written by W. Thompson.

The writer was recently called upon to design and erect a number of mine bulkheads which required to be absolutely free from danger of collapse and fracture and possibilities of leakage. After consideration of the many classes of material available for this purpose, and various designs of construction, the following general design was decided upon and followed:

Materials.—Materials chosen for tbe erection of the bulkheads were hard burned, repressed brick, manufactured from clay fouud at Claytou, in the State of Washingtou, U. S. A., Portland cement, and clean river sand found locally. Before being used, samples of all materials were tested in the laboratories of J. T. Donald and McGill University, Montreal, Quebec.

Design of Bulkheads.—In each case the pressure exerted from the head of water to be retained was in one direction. Bulkheads were, therefore, erected in the form of an arch set against footings cut into the solid rock, footings also being cut into the roof and floor of the workings to remove loose or fractured material and make perfect seal against leakage at point of contact between brick work and walls

*Paper read at the Annual Meeting of the Canadian Mining Institute.

of drift. The first arch was reinforced by a second arch of similar design and the space between the intrados and extrados of the two arches filled with strong cement concrete. The extrados of the fiual arch was also sealed by strong cement concrete faced with 2-inch cedar plank. The strougest and most perfectly shaped brick were chosen for the construction of the main arches and the mortar used consisted of two parts saud to one cement, freshly mixed as required.

STRENGTH OF MATERIALS.—Brick: Transverse test: Distance between centers of support in each case, 6 inches; specimens tested on flat; breaking load at center in pounds, arch brick, 6500 pounds; breaking load at center in pounds, face brick, 3900 pounds.

COMPRESSION TEST.—Load in pounds per square inch at initial failure, arch brick, 6600 pounds; load in pounds per square inch at initial failure, face brick, 2117 pounds; maximum load in pounds per square inch, arch face, 8320 pounds; maximum load in pounds per square inch, face brick, 3242 pounds.

CEMENT.—Tensile strength in pounds per square inch: Neat cement 20% water, at end of sixty days, 699 pounds; one cement and one standard quartz sand, same period, 540 pounds; oue cement and one sand used, same period, 498 pounds.

A 3-inch wrought iron pipe was laid through each bulkhead to carry off water accumulating during construction, this pipe being sealed when water was allowed to accumulate against the face. Bulkheads were maintained free from pressure until material had become thoroughly set.

RESULTS.—Results obtained proved eminently satisfactory, bulkheads proving water tight, and owing to large factor of safety are free from any danger of collapse or fracture.

The Maximum Evaporation.

The United States Geological Survey has been engaged for some time past in making an exhaustive series of investigations on the Colorado river in connection with the proposed reclamation of arid lands along that river. In the course of these investigations a careful record of evaporation has been kept at Yuma, Arizona, under the direction of J. B. Lippencott, engineer in charge of the hydrographic branch of the Geological Survey.

The record for 1903 is given in the following table, together with the precipitation during the same period. It is probable that this represents the maximum evaporation on this continent, unless it be slightly greater in the Salton basin, San Diego county, Cal., or in Death valley, Inyo county, Cal.:

	Evaporation, Inches.	Rainfall, Inch.
January	3.32	.00
February	3.48	.23
March	5.28	.00
April	7.31	.00
May	9.84	.00
June	10.25	.00
July	10.75	.04
August	10 70	.00
September	9.05	.67
October	5.79	.04
November	3.80	.00
December	3.39	.00
Total evaporation	82.86	
Total rainfall	.98	
Net evaporation	81.88	

This gives au average daily evaporation of 0.224 inch throughout the year. The tests were made by placing an evaporating pan in a suitable position on a hill overlooking the Colorado river.

An Advertising Device.

Herewith is a representation of a "Power" steel rope pin which Broderick & Bascom Rope Co. of St. Louis, Mo., are sending to their agents, S. B. Hicks & Sons Co., Seattle, Wash., to deliver to all large buyers of Power steel rope. The pin is of sterling silver, with a gold strand running through the rope, and is a facsimile of the Power steel rope with the yellow strand.

CINNABAR occurs usually in connectiou with metamorphic sandstone and serpentine—at least, this is the condition at the largest and most important miues of the world thus far discovered; but it also occurs in other formations, though more sparingly. In southern California cinnabar occurs in an altered eruptive rock in Orange county. In Mariposa county, Cal., it is found in the gold belt associated with altered diabase; in Utah in limestone; in Yavapai county, Ariz., in rhyolite with hematite; in Yuma county, Ariz., in quartzite; in Texas in sandstone, etc., showing that the occurrence of the mineral is not confined to any particular kind of rock.

Extracts From a Mining Engineer's Pocket Diary.

A little nonsense, now and then,
Is relished by the best of men.

In the practice of his profession the mining engineer is frequently called upon to leave a comfortable home and office to go to distant points to make examinations. At such times there are feelings and emotious aroused by the change which must be experienced to be appreciated. To those who have had this experience the following paragraphs, taken verbatim from an engineer's diary, will appeal directly. Upon leaving home there is little to cheer or console, other than the hope of a speedy return, but a few days of keen mountain air, several hours of vigorous exercise daily, aud time and mind fully occupied, work wondrous changes:

January 24—Left the city at 11:30 P. M. by —— railway. J. accompanies me for the sake of the trip. How stuffy and uncomfortable these sleepers are and what "back numbers." The company should be ashamed of them—an imposition upon the traveling public.

January 25—Arrived at C—— at 6 A. M. Porter roused us in plenty of time. Had a wretched breakfast at a miserable "high-stool counter" restaurant in the rear of a bar room. Immediately after took the mule team and buckboard, which were waiting for us, and drove over the finest mountain road I have seen in California. We lunched at H——, a typical, old fashioned, California mountain town. Straight, up and down, two-story boxes for houses, with small windows, and eaves so short that they look as if there were none; lean-to porches, with lazy old men sitting about upon them hoping that some one will ask them to drink. After feeding ourselves and the team we drove on through V—— and 4 miles beyond to the mine camp, reaching our destination about 6. Distance from railway about 40 miles. Patches of snow here and there en route. Watchman tbo only man employed about the property. His name is F——. It appears that I knew him in Mexico. Nice steady fellow. He has with him another man—for companionship, I judge. The other fellow very loquacious—promises to be a nuisance. Says his name is "Mr. Aloysius Gatherwait;" but people call him "Nick" for short. Camp well stocked with food; fresh meat consists of venison, which, as it is "close season," is called "prospectors' mutton."

January 26—Nick even talks in his sleep. Several times during tbe night we heard F—— wake him up and tell him to "shut up." Up early and inspected mill, tramway and surface improvements at tbe camp. Find a fairly good assay office; but there are no supplies for it on hand. It will save time and trouble if tbe samples can be assayed here. Set Nick to cleaning up tbe assay office. In the afternoon drove down to V——, where we found five cans of gasoline, which we bought. We also telephoned to the city to have fluxes and crucibles sent by express to C——. The air is fino and most invigorating at this elevation, which, by aneroid without temperature correction, is 4000 feet above sea level.

January 27—Started Nick for C—— with tbe buckboard to fetch the assay supplies. Wbile F—— was rounding up two mules I started to walk up tbe mountain to the mine. The trail is good, but rather steep. The difference in elevation between office at camp and tbe portal of the main adit is about 1000 feet, wbile the distance between the two points is only half a mile. It is surprising bow soft one gets about town for a month or so. I was fairly dripping sweat and blowing like a "roaring" horse when J—— overtook me with bis mule about half way up and let me ride the rest of tbe way. I note tbat F—— is wise enough to mount the slower mule and keep discreetly behind. I find there is no plan of the workings; so that is the first thing to be done. I have started on this work—it will have to be "needle work." There is no local attraction I discover which helps, as I will only have to "set up" at every other station. The work was a trifle awkward at starting, as surveying was new to both J—— and F——. J—— is very good about "pitching in" and helping. Put in a good, long day's work. Very tired at nigbt. I note that the vein is soft and well defined; so that the sampling will be comparatively easy of accomplishment.

January 28—Slept like a brick last night and felt like a "fighting cock" this morning. Got an early start; took tbe precaution of securing the fast mule and tbe first start on the way to the mine, tbus leaving J—— and F—— to settle the "ride and tie" question between them. To my amusement J—— was a close second to me and F—— walked all the way. It will do him good, as he rode all the way yesterday. Finished everything connected witb tbe underground work by noon. The lunch looked rather nasty, but it tasted very good. I must say that tbe "prospectors' mutton" begins to pall a trifle. In the afternoon connected all tbe surface openings—cuts, pits, etc.—with the main lines of tbe survey. Also ran a "closing" line to point of beginning as a check.

Platted the survey in the evening. The work closed very well, which is satisfactory. Having no drawing paper, used tbe back of an old blue print, which served tbe purpose. No drawing board, of course; but the dinner table answered. Nick returned, improved in appearance by a bair cut and sbave, but wonderfully drunk. He brought the supplies, and tbe team was all right, and be is speecbless; so it is all for the best.

January 29—It is wonderful how one feels in this fine, bracing air. I am actually hungry for work. Spent the time till 3 P. M. taking samples and notes; then returned to camp and instructed Nick in the mysteries of mortar, buckboarding and sieves. I am singularly fortunate in being quite free from fear of "salting" on this job. Nick is a positive comfort, being repentant and also shamed into absolute silence.

January 30—At mine all day with F—— finishing up the sampling and studying the conditions of the shoots of ore and going over the surface and croppings. The problems are simple, but rather interesting. Nick, under the watcbful and intelligent eye of J——, has been employed all day in reducing yesterday's samples to pulp.

Spent the evening noting points at which samples were taken and the vein widths upon the plan. No "eight-hours" rule apply to jobs of tbis kind.

January 31—Spent the whole day assaying. Nick broke up yesterday's samples. J—— helped me, weighing pulp and mixing fluxes. By night had all the samples fused and the buttons cupelled. A good, satisfactory day's work. Nick still silent—he does not feel quite well. His only remark was elicited by my remonstrance upon bis taking down a quarter pint bottle of castor oil. He said he "knew what was good for him." The "prospector's mutton" has grown repugnant to me.

February 1—Up early. Parted and weighed up all the assays. Finished by 1 o'clock. After lunch hitched up and started to tbe railway, taking advantage of sublime moonlight. Passing tbrougb H—— noted that my first impression was erroneous. It is a pretty little place, and the wbite frame houses, with their comfortable verandas, are in keeping with their surroundings. The old men sitting about are picturesque and venerable patriarchs and their philosophy has, no doubt, brougbt them to a quiet and congenial resting place. Reached C—— at 9 P. M. It is a live and bustling, even though small, railway station. Enjoyed an excellent supper of eggs and beefsteak at the lunch counter. The food is surprisingly good and well cooked and clean. Caught the train at 11. Fine sleeper. It is astonishing how luxurious railway travel is in these days. The —— railway, particularly, seems to do everything for the comfort and convenience of its patrons.

February 2—Reached tbe city at 7 A. M. After breakfast started upon my report. Made a new plan upon tracing cloth, also sections; took these to be blue printed.

February 3—Finished rough draft of report. Blue prints came in. They look very nice. After all, very few can get up such a set of drawings as I can when I try.

February 4—Revised report and had it typewritten.

February 5—Turned in report and drawings to clients. They seemed pleased and asked me what my fee was, and paid me by check. All very satisfactory. Next!

Safety Devices in Hoisting.

TO THE EDITOR:—In your editorial of February 6th you say:

"The second count, that 'no safety device was attached to the cable to prevent overwinding,' is a suggestion of doubtful utility. A hoisting engine usually possesses power far in excess of that necessary to lift the load it hoists from the mine. A clip, or other device on the cable, would scarcely have the effect of stoppiug the engine, while the strain on the cable would probably cause it to part the moment the safety device on the cable came in contact with some firm obstruction. The provision of bumpers ou the guides to prevent overwinding would seemingly be a better device, when if the cage were provided with the usual safety clutches these would immediately operate, should the cable break, if the clutches were in good working condition, with a chauce of holding the cage, as it had acquired no momentum."

A device to "prevent overwinding" is, as you say, of doubtful utility—you might have said, entirely useless. The clip or bumpers you suggest would probably be unsatisfactory. When making recommendations the jury seem to have overlooked or forgotten the devices made, and in use, for detaching the cable from the cage in case of overwinding. I have for years used at several mines a detaching clamp, which never failed to work. If the cage is brought within danger distance of the sheave the cable is automatically released from the cage. At the same instant heavy lugs are throwu out which rest on a thick iron plate, holding the cage securely. The ordinary safety dogs, or catches, will also be thrown into use and grip the guides.

For several years I have tested this device once a month. At the tests the throttle on the engine was opened wide and the cage allowed to rush to destruction—or be saved by the detaching device. Never did the appliauce fail to work. The cable was invariably detached and ran over the sheave, and the lugs held the cage securely. Then to complete the testing the cable was brought back and reattached, aud the cage hung by a short piece of rope between the cable and cage. The rope was cut and the cage allowed to drop. I never knew it to go more than one-fourth or one-half inch before the dogs took hold.

This detaching device can be bought from machinery houses.

The recommendation of the jury for "a safety device to attach to the cable to prevent overwinding" was conceived in ignorance. No successful device has been made to prevent overwinding—whether attached to the cable or not.

To avoid serious results from such accidents provide a device for detaching the cable, and also good safety clutches. Test once a week by overwinding and dropping the cage. Accidents may occur from other causes which might also be prevented, but that is not the subject under discussion.

Referring to the broken valve on the hoist of your Middleton correspondent, I would say I always equip hoists with two throttles—one just above the other—one being always open and idle, but ready to use in just such emergencies, as your correspondent mentions.

G. A. SINGER.

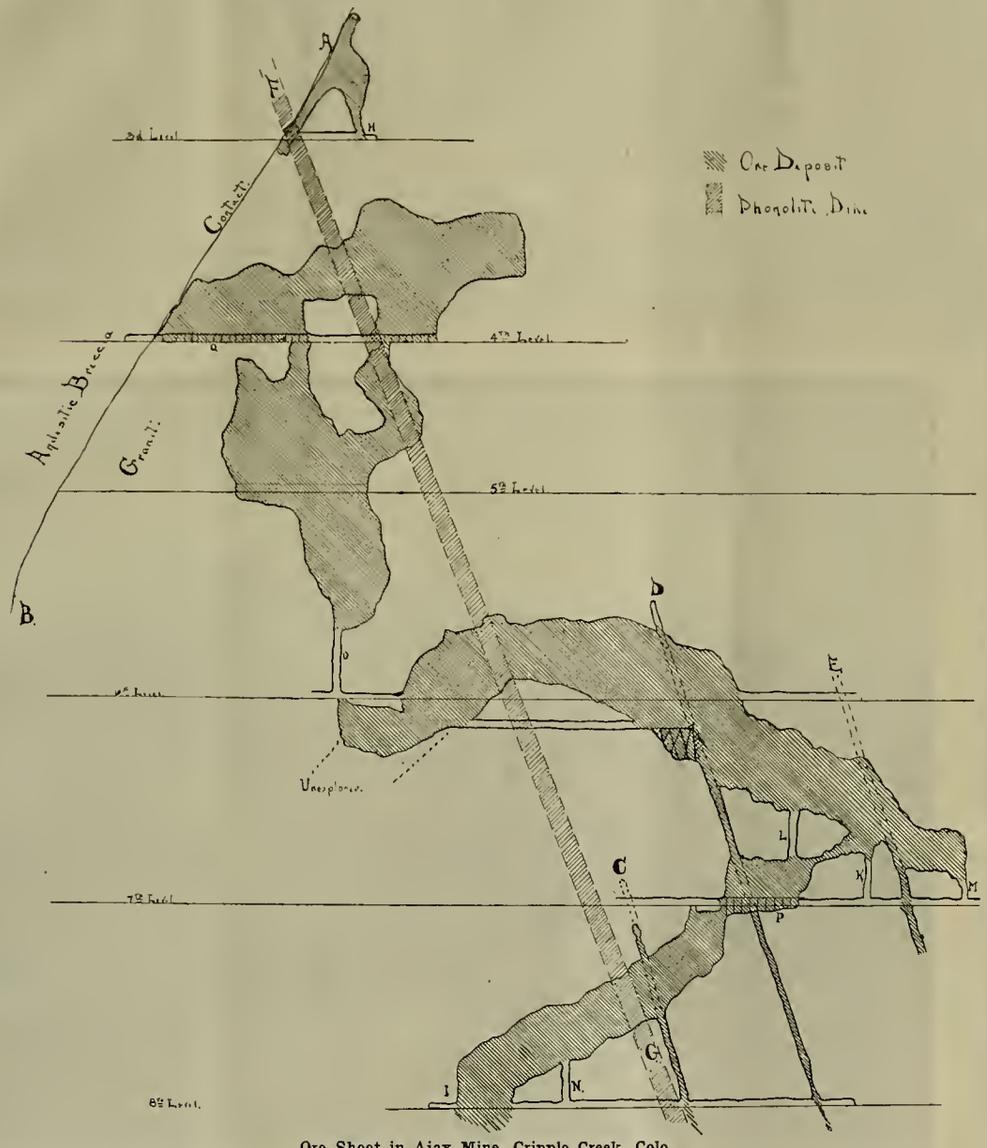
Woedsky, Alaska, Feb. 29.

A Peculiar Ore Deposit.

Written for the MINING AND SCIENTIFIC PRESS by E. A. COLBURN.

One of the main ore shoots of the Ajax mine, Victor, Colo., is located in the granite, near and in some places touching the main southern contact (A–B) between the granite and the audesitic breccia of the Cripple Creek volcano, on or near which contact most of the larger mines of the district are located.

As may be seen in the accompanying sketch, the ore shoot has a very irregular course, in some places even "jumping," as it is locally called, for a number of feet, with no connection other than the joint planes in the intermediary granite. These joint planes are often filled with a white or grey gouge, probably composed of kaolin and other decomposition products, and do not, in most cases, carry appreciable values. It being impossible, on account of its winding course, to make an accurate section along one line, a sketch was made of the deposit as it would appear from the side.



Ore Shoot in Ajax Mine, Cripple Creek, Colo.

At intervals veins, three in number, leave the main ore body and follow the joint planes downward (C, D, E), carrying a good grade of ore as far as prospected, but in no case do they carry sufficient values above the main deposit to warrant their being worked. Neither the main ore shoot nor the smaller veins have any definite walls, but fade into the surrounding granite in a way which often deceives the miner into passing by a good body of ore. The width of the ore is from 15 to 30 feet, averaging, as a rule, about 20 feet; the height is a trifle greater than the width and is usually in proportion to it. The small veins are from 2 to 3 feet wide and 50 to 100 feet in length.

Three dikes cut this ore shoot, two phonolite and one basalt. The larger phonolite dike (F–G), which is about 10 feet wide, cuts the ore diagonally in three different places and was probably forced through the country after the ore was deposited, as it shows no sign of mineralization other than a small amount of iron pyrites. The second or smaller phonolite dike follows the ore from the 800-foot level all the way up to the 300-foot level; it was probably intruded later than the larger dike, which it cuts, and in its course through the ore often pinches to a seam, never having a greater width than 6 inches except when the country rock is reached, where it widens to 3 or 4 feet. The basalt dike cuts the ore only in one place between the 500 and 600-foot levels, but lies quite close to the body throughout its whole vertical distance.

The ore was first discovered at the 300-foot point in 1894 (H), and was not supposed to have any great extent as it pinched out after about 75 feet of stoping and did not appear to go down. In 1896 the main shaft was sunk through the ore at the 500-foot level, but it was not until 1901 that the ore was again located by a crosscut on the 800-foot level (I), below which it has not yet been opened.

The ore is partially altered granite, the ferromagnesian minerals (mica, hornblende, etc.) being replaced by quartz, in places associated with fluorspar, the whole mass being stained a light green by the protoxides of iron. Of course this leaves small quartz-lined holes or vugs all through the ore, which give it a cellular or honeycombed structure very characteristic of this deposit. These cells are often, in the richer ore, occupied by crystals of calaverite, picked samples of which have assayed as high as $180,000 per ton.

One of the most remarkable features of the ore is that the phenocrysts of orthoclase feldspar in the original granite have remained unchanged, both in color and in form, as far as the unaided eye can determine. There is no indication of a vein structure other than the joint planes that are continuous through the ore from the country rock, and the drusy, quartz-lined vugs about 3 inches in diameter which occur here and there in the ore. The ore was probably formed by slowly percolating mineral-bearing solutions which impregnated and partially replaced the country rock through which their movement was directed. E. W. Brooks of Cripple Creek says of this deposit: "There are some reasons which, to my mind, indicate a "contact" origin to this class of deposits in the district. That is to say, the genesis of the ore may be traceable to the mineralizing effect of the contact between the granite and the breccia at points where intruded dikes have furnished not only heat, but gases for pneumatolitic effects. The irregularity of the deposit seems to indicate either a crushed or sheared zone, which at certain points was accompanied by much shattering of the granite, or previous action of thermal waters furnished the necessary porous, cellular condition, afterward sought out by the mineralizing solutions."

As the surrounding country rock is very hard and does not slack off or cave, the deposit is worked without any timber other than the first course of square sets on each level (P, Q), only enough ore being drawn off to give the miners room to work next the back. On account of the low pitch of the shoot, raises often have to be run from the levels to avoid shoveling in the stope (K, L, M, N). As soon as the stoping is completed the ore is "drawn," leaving a great untimbered chimney, which is never filled with waste on account of the probability of ore being found in the immediate vicinity.

Colorado Mineral Output for 1903.

The mineral output of the State of Colorado for the year 1903 has been issued by Mine Commissioner E. L. White, and is given in the following table:

COUNTY.	Gold, Fine Ounces.	Silver, Fine Ounces.	Lead, Pounds.	Copper, Pounds.	Zinc, Pounds.	Total Value, Dollars.
Arapahoe	8	.....	.....	.....	.....	165 36
Archuleta	3	6	.....	.....	.....	65 22
Boulder	20,879	61,833	115,100	6,154	.....	470,300 94

Teller	572,824	41,605	.....	.....	.....	11,862,509 95
Totals	1,945,242	13,245,483	191,513,514	7,809,920	80,616,000	38,377,999 75

NOTE.—In the above table the calculation of value is on the average market price of the metals for the year: Gold, $20.67; silver, .5345; lead, .04237; copper, .13235; zinc, .054.

The report shows a decrease in mineral output of nearly $6,500,000. This decrease is chiefly in gold, the output for 1902 being nearly $7,000,000 greater than in 1903. The falling off in the gold output is due largely to labor troubles. The decrease in the output of silver was about $1,200,000, though the average price of that metal was higher than in 1902. The copper production remained about the same, but, owing to the newly discovered method of separating zinc from the complex ores of many of the most important districts, notably at Leadville, the zinc output was raised from $2,544,993.48 in 1902 to $4,353,264.00 in 1903.

The Mines of Groom Creek, Arizona.*

There has been unusual activity on Groom creek, in Yavapai Co., Ariz., the past few years, and a number of mines of importance are developed, equipped and in operation there. Groom creek rises near Spruce mountain, about 10 miles southeast of Prescott, and, flowing in a southwesterly direction, joins the Hassayampa creek, 8 miles south of Prescott. The greater part of its course is through a granitic area in which are some small veins of high-grade ore; but in its upper portion it cuts through metamorphic rocks, and in that vicinity is found the greater mineralization.

Among the mines on Upper Groom creek, the Monte Cristo is in operation. It has a shaft down 400 feet and is equipped with a hoist and 10-stamp mill. The mill is illustrated in engraving on front page. The ores contain gold, silver, lead, copper and some zinc. Above the Monte Cristo, the Home Run Company has developed a mine 400 feet deep on a vein 3 feet wide. On the 300 level the vein has been extensively drifted, and on the 400 level the drift is in over 200 feet. The property is equipped with steam hoist and stamp mill. The Home Run mill is also illustrated on the front page. Beside these, there are other properties on the creek which are attracting attention.

Over the divide from the head of the creek are the mines of Upper Lynx creek, described herein in the issue of March 12. The entire section of country east and southeast of Prescott drained by the Hassayampa and its tributaries, Lynx creek and the streams flowing easterly from Las Barretas, Mount Union and the neighboring spurs is mineral country, in which some prospecting has been done to a depth of 400 or 500 feet. The results having proven satisfactory, an era of deeper mining may now be anticipated. The ores usually contain gold and copper; silver, lead and zinc also occur in most of the sulphide ores, but in some instances iron sulphide is the chief carrier of precious metals.

*See Illustrations on front page.

A New Town on the Mojave Desert.

A large portion of the southern portion of California—that portion south of the Tehachapi mountains—is desert—a vast arid territory covering tbousands of square miles, and extending eastward into Nevada and Arizona, in which the annual rainfall is a minimum, and where the range of temperature is represented by 140°, while the mean temperature is far above the average of the rest of the Pacific coast. The range of temperature within twenty-four hours is sometimes nearly 100°. The effect of such uuusual climatic couditions is to produce a desert—rugged serrated mountains separated by broad, flat valleys with no sign of verdure other than sparsely scattered sagebrush and greasewood. An occasional clump of mesquite is the only really beautiful thiug to be seen in desert valleys. Often the central portion of a valley is flat as a floor, and is composed of a broad expanse of fine silt or clay as hard as pavement and glaring white in the fierce sunlight—the bed of a dry lake.

The vision may clearly distinguish mountains 150 miles distant through the clear, dry atmosphere. The distant mountains seem near, and those near at hand are startling in their barren ruggedness. Out of this laud of silence and death rise scorcs of such ranges, isolated buttes, and rounded hills, and few of them there are which do not contain mineral veins or deposits of value. Among these the names of many have already become familiar to the miner and prospector—the gold mines of Randsburg, and those of the Panamint section, of Slate range and of Death valley; the silver veins and borax deposits of Calico, the gold, silver and copper of Providence mountains, and the gold of the Cargo Muchacho range; the silver and copper of Lava Beds district, and the gold of Pinon mountains. These are only a few of those already noted in the Mojave and Colorado desert region. And now a new camp has sprung up in a new district, that of Rochester, in San Bernardiuo county, about 40 miles east of Daggett, and 8 miles southwest of Ludlow station on the Santa Fe railroad. The accompanying engraving presents a characteristic picture of desert mountain and long, low valley slopes, with the scanty sagebrush with intervening patches of barren sand. At the lower eud of the village on the left are the Bagdad mines, owned by the Bagdad-Chase Mining Co. of New York, E. H. Stagg, manager. Immediately behind the observer aud half a mile distant are the mines comprising the Chase group, owued by this compauy. To the right of the Bagdad group in the middle background of the picture are the mines of the Roosevelt group, a separate property owned by the Roosevelt Mining & Milling Co. The Bagdad mines produce ores containing gold and copper. The company owns a 50-stamp mill at Barstow, 60 miles westerly from the mines on the Santa Fe, and near the Mojave river. A new 10-stamp mill and cyanide plant is being built at the mines. The Roosevelt Co. are also building a 10-stamp mill. The water for these mills is to be pumped from wells sunk in a dry lake some distance from the mill sites. Within a radius of 10 miles of this camp are several extinct cinder cones of typical form, marking the site of as many volcanic vents, which are the seats of the dying volcanic activity whicb has in the past been such a promiuent characteristic of this portion of the desert. The oldest rocks of the region are iutrusive—diorites and quartz porphyries, and later, ofteu overlying these, are rhyolites, rhyolite tuff and breccia, andesites, etc., and still later the black olivine basalts, wbich coming up through the volcanic vents, spread over many square miles of the country. The indications are that the most recent eruptions were of a quiet kiud, in which the lava rose in the craters aud overflowed, the molten rock extending in some instances 10 or 12 miles from the craters. Later the cinder cones were built up about the vents and the interual fires slumbered. How long these volcanoes have been silent no one knows, but the lava looks startlingly fresh to one who walks over its rough, twisted and gnarled surface. The large amount of ashes aud tuff formiug hills iu the region south of Lavic, a statiou west of Ludlow, indicates that prior to the basalt flow the volcanic activity of the region was of a violent type, in which vast amounts of matcrial were ejected.

None of these signs of former disturbauce have deterred the owners of these mines from expending a large amount of money iu their development. Among other improvements is a standard gauge railroad 8 miles in length, connecting the mines with the station on the Santa Fe railroad at Ludlow. The establishment of this camp will doubtless do much toward stimulating prospecting and mine development in tbe mountains of the vicinity, in some of which there are mineral deposits of proven valuc, notably in the Lava Beds hills, a few miles west of Rochester, where are veins of gold, silver and copper ores, and farther westward large deposits of irou ore—hematite and maguetite of good quality. The vast region of the desert has only bcen superficially prospected as yet, aud it is more than likely that with increasing knowledge of its resources, and improvemeut in means and cost of trausportation the desert will be robbed of its terrors aud many other mines will be opeued in the future.

Some Notes Concerning Tin.

Written for the MINING AND SCIENTIFIC PRESS by JOHN W. GRAY.

Mines of this metal iu Cornwall, England, have been worked since long before the Christian Era. It is extensively mined now in various countries, and it is difficult to overestimate the value of the metal in the ordinary uses of life, many of which are so well known to us all.

Tin is said to be found in the native state in small quantity in the alluvial gold deposits of Siberia, Guiana and Bolivia. The great commercial ore of the metal is called cassiterite, or tinstone. The ore washed out of its veins and deposited along with gravel, sand, etc., is called "stream tin," or black tin, and "wood tin" is a variety resembling petrified wood. There is also a sulphide ore called stannite, or tin pyrites, containing about 26% of tin, usually associated with pyrites of iron and copper, and called "bell metal ore," because of its frequent bronze appearance, but it is not usually a plentiful or valuable ore.

Cassiterite is an oxide of tin and has a hardness of 6 to 7 and a specific gravity of 6.4 to 7.1. When pure, which is rare, it is colorless or transparent; but it is usually brown to black, though sometimes gray, white or red. Transparent red or colorless specimens are quite rare. It crystallizes in square prisms and octahedrons, with high luster, and also occurs massive and in grains. Before the blowpipe, with carbonate of soda on charcoal, a button of tin is obtained. This, dissolved in hydrochloric acid with metallic zinc added, will be deposited in sponge form. On the charcoal a white deposit is formed, which can not be driven off aud which moistened with nitrate of cobalt solution becomes bluish green, a distinguishing test.

Cassiterite frequently resembles the common brown garnet, black zincblende and some varieties of tourmaline. It occurs in veins in the primary rocks and in alluvial and drift deposits. It is usually associated witb quartz, mica, fluorspar, apatite, feldspar, tourmaline, topaz, chlorite, sulphurets of various metals, mispickel, specular and magnetic iron ores, wolfram and molybdeuite, and appears to find a very congenial home in granite or between vein walls of granite.

In workable quantities tin seems less universally distributed than many of the valuable and useful metals. In a table below will be fouud mention of the countries which produce in quantity the tin which supplies the markets of the world.

Some reference to the occurrence of tinstone aud the methods of extraction will probably be of interest, as indicating, in a geueral way, the distribution and production of the metal. About one-half of the present production which finds its way to the general markets comes from the Straits Settlements, or, more properly, the Federated Malay States, of which the State of Perak is the largest producer, and nine-tenths of the total production is from the alluvial workings. Many lodes, however, are known to exist and some are profitably worked. The lodes are said to vary from 2 feet to 10 feet in width, and one lode is reported to yield a considerable amount of ore averaging 3.5% tin. The prevailing rocks are quartzites, scbists, sandstones, clay slates and granite—geology of lodes somewhat similar to those of Cornwall, granite with overlying slates and schists. The ore in lodes and wash is cassiterite, averaging from 68% to 77% tin. The alluvial deposits occur on the hills, at the foot of the mountains and in the low valleys in areas of varying extent. The ore occurs from fine dust to large pieces of several hundred weight. It is sometimes distributed uniformly, but often in layers and on the bedrock, and at depths from the surface to as much as 150 feet. Usually there is quite a depth of overburden. The wash in producing layers is a mixture of granite and some other rocks, and the impurities which render dressing troublesome are magnetic and titaniferous iron ore, mispickel, iron pyrites, tourmaline and wolframite. The yield of the alluvium is from ½% tin ore up to as much as 50% in the concentrated layers and pockets in the bedrock. One per cent is a profitable yield and 3% or more is considered very rich. The ore comes from the disintegration of the rocks. It has been found in quantity as a constituent of the granite, but the granite itself has not been successfully worked. The method of working is by open cuts or pits, and, when the overburden is heavy, by shafts. The ore is separated by crude methods of puddling and such other hydraulic methods as local conditions suggest. The gravel is run into sluices with riffles, and, when it has been washed away, the residue caught is treated in pans or sbort boxes. Of late, by proper hydraulic equipment, very successful methods of work have been established. The country being well watered affords opportunity for this method of operation. It is also proposed to utilize dredgers on the streams.

CAMP ROCHESTER, SAN

The next largest supply of tiu comes from the Dutch possessions in the Indiau Archipelago. Extensive fields exist in the islauds of Banca, Billiton aud Sumatra, and it is said that the production of tin from these sources can be largely increased at auy time at the will of the Dutch Government. The present production is mainly from the alluvial deposits, but the ore has been traced to its sources, which are veins in the granite and gneiss, and in the overlying quartz schists, clay slates and sandstones. A typical alluvial deposit is said to be somewhat as follows from the bedrock up: An average of 3 feet of tin wash, then coarse sand followed by layers of differeut colored clays, then sand with a little ore, and then tbe overburden of vegetable mold. This overburden is from 25 to 30 feet deep. The cassiterite or black tin recovered is said to average about 71% metal. In Sumatra the gravel deposits are found on the west coast and are said to average about 1% tin. The localities, however, are hard to reach, and the dense vegetation makes prospecting difficult.

Next to the East Indies comes Bolivia as a producer of tin. The deposits are found in a stretch of land several hundred miles long and of a considerable widtb in the southwestern part of the country,

chiefly in the departments of Potosi, Oruro and La Paz, the larger number of mines being in the department of Oruro. The veins are reported to occur in the granite or cutting through the country shales. The mines are at a very high altitude and lack transportation and other facilities for the very best results; but the field is promising, and with more capital and improved methods of work it is thought profitable production could be largely increased. The veins are of good width and of satisfactory richness. The average contents of the best ore is reported to be from 10% to 12% tin, the concentrates averaging about 69%. The lode matter is silica, alumina and iron oxide. The veins are richest when the filling is soft material, the ore occurring in grains and nodules, but the veins are usually solid and the country rock hard. The Potosi production is chiefly from the tailings of silver mines, and in the department of Oruro many of the silver mines carry from 2% to 4% tin. This tin is separated by concentrating the lixiviated tailings.

Next in production comes Australasia. Here tin is produced in West Australia, Queensland, New South Wales, and also from Tasmania, the latter being the largest producer. Both lode claims and alluvial deposits are worked successfully, and in some cases both together, as at the Mount Bischoff mine, Tasmania. The sources of the stream tin are river and creek beds and drift deposits. The gravels are composed of the eroded rocks, enriched by portions

ARDINO COUNTY, CAL.

of the old drifts cut by the younger drainage lines. The beds of old streams lie below the alluvial wash, and claims have been found richer by sinking to these channels. The deposits are sometimes covered by lava. The veins are found in the granite and overlying rocks. At the Mount Bischoff mine the ore is found in alluvial beds, in lodes and in stockworks or pockets. A dyke of eurite and porphyry is described as having broken through the slates and sandstones, and the latter rocks at the contact are cracked and broken and the fissures filled with tin ore and arsenical and copper pyrites. The yield is variable. For six months in 1902 the average value of concentrates from ore was reported at 1.312%. Extensive hydraulic operations are carried on in Tasmania, and by this means very low-grade material is worked at a profit. In Tasmania, Queensland and New South Wales dredgers are said to work with success, and it is believed in suitable locations steam shovels could be profitably used. In Queensland several extensive and unusually rich lodes are reported, and some veins have been successfully worked to a depth of 800 feet. The field for the production of tin in Australia is large, and it is thought the industry of tin mining there will be greatly extended.

Cornwall, England, follows Australia in production. This region has supplied tin, as before stated, since before the Christian Era, and both stream and lode tin have been largely produced. The lodes occur chiefly in granite and traverse the granite and overlying slate. It is a common occurrence for the veins to carry copper in the slate and tin in the granite beneath. The tinstone is described as mostly associated with quartz, with some chlorite, fluorspar, oxide of iron, clay and iron and copper pyrites. The veins vary in occurrence and size and in the amount of tinstone contained. The mines have been very extensively worked and the concentrates contain about 66% tin. Some figures for the Dolcoath and Wheal Grenville mines in 1902 gave a yield of 51.8 pounds tin per ton for the former and 43.6 pounds for the latter. Cornwall presents the best types of the operations of mining for tin, but the production is decreasing.

A certain amount of tin is produced in some other countries, but not sufficient to be of much commercial importance.

In the United States there is no production. Tin ore has been found in California, South Dakota, North Carolina, Texas and some other localities; but so far very little tin has been produced. Large sums of money have been spent in attempts to mine the ore, notably in California and South Dakota, and smaller sums in North Carolina, Virginia, Texas and other places, but all without success,* notwithstanding the fact that some of the deposits seem promising. In Alaska, at several points on the Seward peninsula, tin ore has been discovered, and geologists assert the region to be attractive. A certain amount of stream tin has been collected, and in one instance, near Port Clarence, it is reported the ore has been traced to its source, a large granite dyke cutting the limestone of that region and containing the tinstone in payable quantity. It is also reported that a large area of ground near York has been discovered, of an average depth of 6 feet, the whole containing more or less tinstone. Nothing very definite, however, about the region is yet known; but it appears certain that in some places tin ore has been found in quantity, and the section of country is reported as promising by good authority.

It also has been lately asserted that in Burmah, where some tin deposits were already known, new fields of large extent and more than usual richness have been discovered.

In the operation of reducing tin from its ore, the material is crushed and then concentrated by some approved method. The ore is then roasted, smelted in reverberatory or stack furnaces and afterwards refined.

The production of tin for the year 1903 by those countries from which practically the supply of the world is obtained is given as follows by a trade publication, based upon the trade statistics:

	Tons.
Malay Peninsula	54,797
Banca	15,070
Billiton	3,653
Bolivia	9,500
Australia	4,991
Cornwall	4,150
Miscellaneous	375

An unknown amount is produced in China, variously estimated by different authorities, but it is mostly consumed in that country. A few other countries also have a small production, but the amount is insignificant.

The consumption of the United States during the year is estimated at about 39,000 tons, all of which comes from abroad, mostly from the Malay Peninsula.

The world's production is increasing very slowly, if at all. The supply does not exceed the demand. New fields are needed, and should they be discovered within the jurisdiction of the United States, it would be of distinct benefit to this country and a most desirable extension of our mining industry.

The price of tin for the past year in New York City ranged from 23.54 cents to 29.85 cents per pound, and in London the price varied from $111.10 to $133.10 per ton.

As has been stated, tin is a most important metal, and it is in almost universal demand. It is used in castings and for the coating of other metals, especially iron and copper. It is needed for various alloys, such as solder, the different kinds of bronze, gun metal, bell metal, etc. It is consumed extensively in the manufacture of tinfoil. With quicksilver, it is used to cover glass for mirrors. Its oxide is used as a paste for sharpening fine-cutting instruments; its chlorides are important in dyeing and calico printing, and its bisulphide, which has a golden luster, is used for ornamental painting, paper hangings and various other purposes.

*No information regarding tests being made at Tinton, S. D., have yet been made public.—Ed.

Bore Holes for Pumping Purposes.*

Written by Edward S. Wight.

The writer is induced to lay before the members a description of a method by which a bore hole can be used for pumping purposes; not as an engineering feat, but rather to show that the water in the distant workings of a mine may in many cases be delivered direct to the surface, thus saving long ranges of pipes underground, and probably several handlings of water.

At one of the mines under the writer's charge the pumping was done in three stages: No. 1 pump being adjacent to the shaft bottom, No. 2 being 1200 feet inby (distant from the shaft), and No. 3 pump a farther distance of 330 feet inby. No. 2 is 60 feet lower than No. 1 pump, and No. 3 is 50 feet lower than No. 2 pump. The water was pumped from one pump to the other, and No. 1 pump forced the water direct to the surface. As No. 1 pump was far too small to deal with the water made at its own level, and also that delivered to it by No. 2 pump within eight hours, this involved a second shift of pumping.

To avoid using a larger pump instead of No. 1 pump, and also a larger column of pipes to the surface, it was resolved to put down a bore hole on the west side of Waikato river, so as to enable No. 2 pump to force the water direct to the surface. The necessary survey being made, a contract was let to put down a bore hole and line it with a pipe, 5 inches in diameter, the price being 4s 6d per foot for labor only for a depth of 242 feet.

It was known that down to a depth of about 100 feet the bore hole would be made in quicksand, consequently a pipe 6 inches in diameter was driven through this, and through it a pipe 5 inches in diameter would be telescoped. To enable this to be done, it was necessary to slightly turn down the couplings of the pipes, 5 inches in diameter, in order that they might pass through the pipes, 6 inches in diameter. At the bottom of the quicksand, 115 feet deep, a log of wood, 18 inches thick, was struck on one side; and, to prevent the sand from running, it was necessary to drive pipes, 6 inches in diameter, through the log, after it was chipped away sufficiently. It was afterwards found that the driving of the pipe past the log had deflected the hole slightly, and to such a degree that after the hole was pierced into the workings the pipes, 5 inches in diameter, would not travel past the deflection, on account of the couplings being so neat a fit. An endeavor to procure pipes 4½ inches in diameter in the colony proved fruitless; the hole was therefore lined with pipes 4 inches in diameter. These slipped down with freedom, so that the deflection of the bore hole could not have been very great.

The water from No. 2 pump is now forced direct to the surface through the bore hole, and it is intended shortly to work No. 3 pump, at which station there is only a small quantity of water, as a hydraulic, taking the power from the column of No. 2 pump. By this arrangement the water is now easily pumped out in eight hours, and the services of two men dispensed with, effecting a saving of 17s per day. Probably the same result could have been obtained by increasing the size of No. 1 pump, but, considering the circuitous route of the pipes from the pumps to the shaft bottom, and other conditions prevailing, it was considered best to adopt the bore hole, sufficient pipes being released in the distance of 1200 feet to No. 2 pump to almost pay for the work.

The boring machine used for putting down the hole was a percussive rotary machine, using an ordinary chisel on pipe rods, through which water is pumped to bring up the debris, the stroke obtained by a hempen rope wound around a friction drum, the attendant holding the rope end until the necessary lift

*Abstract Trans. N. of England Ins. Min. and Mech. Engrs.

is attained, theu suddenly releasing it and allowing the rope to surge on the drum, and thus any length of stroke cau be obtaiued. Thc turuiug motion of the drill is produced by clamping a toothed wheel upon the rods, the wheel geariug iuto a fluted column, about 5 feet high, and this column is made to revolve at a speed of one revolution of the rods to about every five strokes of the chisel. When starting, the toothed wheel is set near the top of the fluted column, so tbat 4 feet or more can be bored before it need be raised again. It is claimed that the machine is capable of boring almost through any rock, and it has done rapid work when boring for water, where a record of the section of the strata is only a secondary consideration. In Auckland the machine has bored a hole 3 inches in diameter, through the sandstones of the Waitemata 1135 feet deep in eight weeks; in the same locality, a hole 6 inches in diameter was bored to a depth of 400 feet in fifteeu days; at Otahuhu, 9 miles from Auckland, a hole was bored to a depth of 945 feet at a cost of £105, exclusive of coal; and at Huntly, a hole 145 feet deep was bored in one and a half days through quicksand and 30 feet of coal. The best record, however, was through alluvial at Turua, Thames valley, where a hole 3 inches in diameter was bored to a depth of 214 feet in six hours, 74 feet of which was done in one hour. In each instance, eight hours constituted a day's work, the labor attending the machine being a man and a lad.

Although this particular instance of the use of a bore hole for pumping water is only on a small scale, the writer is of opinion that there are many instances where a bore hole might be used to advantage, and long ranges of pipes dispensed with.

The Palma Gold Deposit of Minas, Brazil.*

Written by L. FERRAZ, E. M.

Since 1839 the aboriginal Indians bave been in the habit of paying merchants for their purchases in gold dust. Iu 1842 Father F. S. Linhares, a fugitive from the Minas insurgents, founded the parish of S. Francis de Assis do Capivara, and since then the Indians have occupied themselves in gold washing in the Capivara brook, from which large amounts of gold dust are knowu to have been extracted. The methods employed have been the most rudimentary, shallow holes or shafts being dug in the pay dirt panned. It is stated that as much as $\frac{5}{8}$ to $\frac{1}{2}$ ounce has often been separated from a single panful of gravel. The gold is of high assay, carrying but little silver. Such was the abundance of the output that it served as money for all local transactions. Later on, however, coffee replaced gold as tbe staple product, and mining fell into desuetude.

A short time ago Dr. Alvim, having purchased a small property on which some excavations were needed, was surprised during the course of the work to notice visible gold in the gravel. He commenced panning, recovering twenty grams of gold at slight depth in flakes and small nuggets. This was the motive for the present survey.

TOPOGRAPHY.—The Matto Deutro plantation, which lies about 500 feet above sea level, lies somewhat to the east of the city of Palma (once called Capivara), and about a mile from the station of that name on the Leopoldina Railway. The lands lie on the headwaters of the Capivara brook, which rises in the Serra of thc same title, a spur of the S. Antonio and S. Joao range, the divide between the R. Muriahe to the south and the R. Pomba to the north.

The Capivara is the most important tributary ou the left bank of the R. Eugenho da Serra or Batatal, and it receives the waters of a number of small rills on its left bank. The region recognized as auriferous is limited to the headwaters of these streams, comprising the plautations of Matto Dentro, Praia and Lavras, all on the left bank. The right bank and bed of the Batatal does not contaiu even traces of gold.

GEOLOGY AND MINERALOGY.—The plantation of Matto Dentro is characterized by the crystalline character of the rocks, gneiss predominating, with granites and syenite, and may be referred to the Laurentian age. The writer encountered one Huronian quartzite, no schist at all, no mica schist or limestones. The gneisses are varied in structure, but generally granitiform. The lower beds are of common foliated gueiss, amphibolitic and syenitic gneiss. The granites, some typical, some with amphibolite, pyroxene and garnet, form a series tending towards a true syenite. Veius of granulitic black tourmalines, in prisms of various sizes, separate or agglomerated, and veins of pegmatite, commou or of graphic structure, cut into the primitive masses. The mica of the granites and gneisses is generally biotite, some of it lithia-bearing; some of the gneisses contaiu both biotite and muscovite. Both orthoclase and plagioclase occur. The quartz is white, black, yellow, violet, red and hyacinth.

Two distinct types of rock occur—the miascitic, rich in black mica and ilmenite, and the zirconian, containing a certain proportion of zircon and monazite.

Among the residuary minerals found in the pan-concentrates are the following: Sphene or titanite, rutile, garnets, black tourmalines, graphite, zircon, oligist (hematite), magnetite, disthenite, staurolite aud monazite.

The gneisses have a N.E.-S.W. strike, some dipping to the S.E., others to the N.W., the angle between the two masses beiug about 65°.

The micaceous-pyritic quartzitic outcrops have a N.W.-S.E. direction, dipping S.W. On account of the decomposed state of the superficial blocks, the dip could not be measured.

THE GOLD DEPOSIT.—Gold is found in a state of great purity, as flakes, grains and small nuggets, in alluvial gravels which cover the river beds and the area subject to floods, as well as the country surrounding the headwaters of the streams previously detailed. The pan-concentrates consist chiefly of quartz graius, titaniferous minerals, such as ilmenite, titanite and rutile; almandine and pyrope garnets and melanite; black tourmaline and monazite. Oligist (hematite) and magnetite occur in diminished proportion. Wherever the gravel be panned, more or less gold is found. The average value of this gravel per cubic meter is not less than five grams, equal to 9s per cubic yard. It would only be possible to estimate the mass of auriferous gravels present by means of methodical soundings, which time considerations did not admit of.

Proceeding through the various surveys carried out in the auriferous basin, the writer found:

1. Visible gold in small grains, in a scbistose granitoid pyritic gneiss, which crops out about 500 meters from the river at a spot called Fazenda Velha.

2. Gold, not visible, in two outcrops of quartzite of a greyish color, containing specular iron, mica and mispickel. These quartzites are traversed by narrow stringers of white quartz and occupy the superior part of the headwaters of the Porteira and Pasto brooks, seemingly forming part of the main auriferous basin. All the gravels of these streams are auriferous.

3. Gold, uot visible, in small pyritic nuclei, in a granitoid syenitic gneiss.

MONAZITIC SANDS.—Monazite constantly appears in greater or less amount in the pan-coucentrates. It is possible that rich and important beds exist, seeing that one pan residue contained 20% of this mineral. The value of this mineral has considerably increased of late years, owing to its high thoria content. From the geological character of the district, it is probable that this is one of the monazite centers, and may possibly be of future industrial importance.

VARIOUS MINERALS.—The writer found in one pan-concentrate a small crystal of beryl of clear green color, and fragments of white quartz with galena.

LOCAL DETAILS.—Extensive forests exist in the neighborhood, with an ample supply of timber for fuel or constructional uses. Water power sufficient for working on a large scale is not available close at hand; but, at a small cost, power could be tapped at no great distance.

In the writer's opinion, the auriferous gravels could be industrially developed by modern dredging and hydraulic methods, by which small mineral values give satisfactory results.

It is advisable to ascertain, by means of sounding or excavation, what mass of pyritic mineral exists, and what its assay value may be.

*Brazilian Mining Review.

New Mining Law in Japan.

The new mining law of Japan contains the following among its provisions:

No persons other than subjects of the empire, or companies duly formed in accordance with the laws thereof, are entitled to acquire mining rights.

The right of mining may be canceled if operations are not commenced witbin one year from the date of the record iu the Mining Register.

Mining taxes will be imposed upon persons entitled to mining rights, but no business tax. No tax upon the mining of iron ores will be imposed.

The tax on mining areas is 40 sen per year for every 1000 tsubo (about 25 cents per acre).

The amount of tax imposed on mining productions shall be 1% of the value thereof.

An additional mining tax may be levied by Hokkaido, Urban and ordinary prefectures, as well as cities, towns and villages, uot exceeding 15% of the principal tax.

THE export of diamonds to the United States in 1862 amounted to only $2080; in 1863, $4971.84; in 1864, $1689.80; in 1872, $520—all Brazilian stones. In 1874 Cape of Good Hope diamonds appear in the list of exports, and amounted in that year to $32,739.90. From 1882 on the exports of diamonds to the United States attain prominence, being in that year $539,740. In 1892 it had risen to $4,765,353, and in 1902 to $5,802,655. In 1903 this large amount was further increased by $8,403,222.

LIGNITE, or brown coal, is a soft coal found in the later geological formations (Cretaceous to recent). It usually contains a large amount of volatile matter. It is inferior in quality to either anthracite or bituminous coal. The lignites shade into the bituminous coals.

Mineral Wealth of Peru.

Peru is one of the richest countries in thc world iu minerals of all kinds; gold, silver, copper, mercury, iron, lead, sulphur, coal, salt, petroleum, etc., being found in abundance, says U. S. Consul Cree, at Callao, and only requires capital and labor to make the Republic renowned for its wealth.

The distribution of minerals in Peruvian provinces is as follows:

Gold fields.—Paucartambo, La Mar, Union, Angaraes, Cajamarca, Otuzco, Luya, Huamachuco, Arequipa, Aymaraes, Huamalies, Carabaya, Sandia, Tayacaja, Ica, and Huanuco.

Gold placers.—Maranon, Inambari, and in almost all the rivers and streams of the eastern region.

Gold quartz.—Pataz, Huamalies, Union, Chumbibilcas, Canete, Paucartambo, Quispicanchi, Convencion, aud Paruro.

Silver.—Hualgayoc, Recuay, Yauli, Huancavelica, Pallasca, Pataz, Cailloma, Castrovirreyna, and Cerro de Pasco.

Copper.—Huaylas, Huaraz, Camana, Yauli, Cerro de Pasco, and Ica.

Mercury.—Huancavelica, Chonta, Dos de Mayo, and Puno.

Iron.—Piura, Larez, Calca, and Huaraz.

Lead.—Huari, Huaraz, Cajamarca, Pallasca, Dos de Mayo, Puno, Huancavelica, and Huarochiri.

Sulphur.—Tumbez, Paita, Chancay, Huaraz, Huarochiri, Camana, Cangallo, Arequipa, Monquegua, and Tarata.

Coal.—Huamalies, Dos de Mayo, Yauyos, Huarochiri, Canta, Tarma, Huaylas, Cerro de Pasco, Caylloma, and Puno.

Salt.—Chancay, Huacho, Pasco, Moquegua, Cuzco, and in nearly all the proviuces on the Pacific coast.

Petroleum —Tumbes, Piura, Lambayeque.

PRODUCTION OF MINERALS.—Gold—It is difficult to give the exact total of gold produced annually in Peru, as the owners of mines do not give out any figures.

Silver and Copper—The main production of silver and copper is obtained at Cerro de Pasco. For several ceuturies this district produced a large amount of silver, although the workiug of the mines was superficial and the system of amalgamation deficient. The depth of the mines very seldom exceeds 150 feet. It is ouly in recent times that the existence of copper in quantities was discovered at Cerro de Pasco. The Cerro de Pasco M. Co. will export within two years 60,000 tons per annum, representing a value of $14,500,000.

Quicksilver—The quicksilver mines of Huancavelica are being developed.

Iron—The exploitation of iron at present is of no great importauce in Peru. A considerable area of this metal is found at Tambogrande (Piura); also in the Provinces of Calca and Larez.

Lead—The lead mines have not been worked up to the present with any profit, owing largely to cost of transportation.

Sulphur—Sulphur exists in abundance in all the volcanoes of the cordillera of the Andes, and occurs in layers. It also occurs extensively near the sea, on the peninsula of Aguja, near Paita, in the Department of Piura.

Coal—Coal produced in this country is anthracite, lignite, pit coal and peat. As no records are kept, it is not possible to state the amount of coal produced in the country, but an estimate places it at about 55,000 tons per annum.

Salt, Nitrate, etc.—Salt is widely distributed in differeut parts of Peru, although the principal salt pits are on the coast and are of easy and cheap exploitation. Owing to the dry atmosphere of the Peruvian coast, different classes of salt have accumulated, as well as nitrate, and other springs of carbonate of soda, magnesia, sulphate of soda, etc. The importation of salt from abroad is prohibited by law. There is an internal revenue tax of 5 cents (Peruvian) per kilogram (2.2 pounds) on salt for domestic consumption and 1.5 cents (Peruvian) per kilogram on salt for industrial purposes.

Petroleum—The whole coast of the Department of Piura produces petroleum, which is the only part of Peru where it is worked. Following was the output for the year 1902:

Talara—Crude petroleum produced about 39,375 tons at 47s per ton, amounting to £92,531 5s ($450,257); the quautity refined produced about 60,000 cases of ten gallons each of kerosene at 8s per case ($117,000), and a small quantity of benzine at 10s per case. A contract has been made to supply the nitrate oficina at Agua Santa at Caleta Buena, Chile, with crude petroleum, which is being used with great success—2000 tons per month being consumed. The steamers owned by this company are the Azov and the Circassian Prince, which carry a cargo of 3000 tons and 2800 tons of crude petroleum each. Drilling continues.

Zorritos—Crude petroleum produced about 8027 tons at 47s per ton, amounting to £18,863 9s ($91,789); the quantity refined produced is about 37,325 cases of ten gallons each of kerosene at 10s per case ($90,814); 1290 cases of gasoline at 14s per case ($4399), and 1302 cases of benzine at 12s per case ($3802).

Mining and Metallurgical Patents.

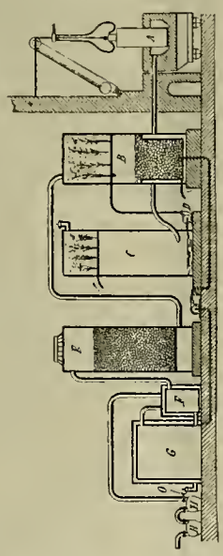
PATENTS ISSUED MARCH 8, 1904.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

Oil Well Packer.—No. 754,138; C. M. Heeter, Butler, Pa.

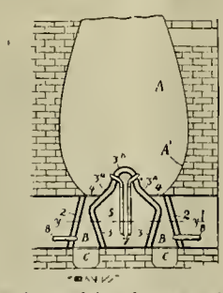
A deep-well casing or tubing, and packer connected thereto by frangible joint, and inner sealing gasket for casing.

Electrical Manufacture of Iron Alloys.—No. 753,875; G. Gin, Paris, France.



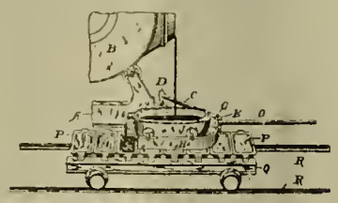
Process for electrically producing an alloy of iron with simultaneous production of oxides of alkalies, consisting of mixing silicic acid with sulphate of alkali, adding carbon to mixture heating same in electric furnace with production of silicate of alkali, then introducing alkali silicate into second furnace, adding oxide of iron and carbon thereto, heating same with production of ferrosilicon and oxide of alkali, and collecting oxide of alkali in form of sublimate of same.

Blast Furnace.—No. 754,337; J. W. Pack, Berkeley, Cal.



Combination in smelting furnace of vertical stack, exterior water jacket and crucible in lower portion, interior hollow water jacket having surrounding space, jacket having upper end entering lower part of stack and having greatest diameter intermediate of ends, whereby downwardly converging passages are formed between inner and outer water jackets, and inner jacket supports and arrest ore passing through bosh or neck of furnace.

Copper-Pouring Spoon.—No. 753,465; B. H. Bennetts, Tacoma, Wash.

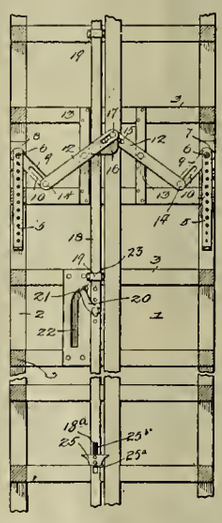


In copper-pouring spoon, combination of horizontal receiving bowl intermediate between converter and molds, U-shaped supporter engaging and supporting bowl, and horizontally-jointed arm secured to and carrying supporter in such manner that bowl may be moved in any direction in horizontal plane.

Strainer for Drive Wells.—No. 753,846; W. H. Broome, Brooklyn, N. Y.

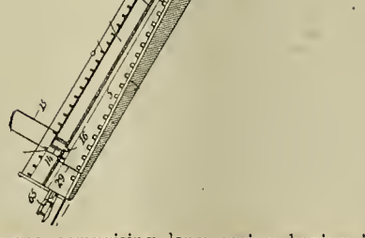
Strainer for drive wells, comprising perforated tube provided with enlarged end members having annular recesses in adjacent ends and around tube, tube being also provided with annular and longitudinal ribs, and in opposite sides thereof with longitudinal grooves or spaces, wire screen placed on tube and strips or plates secured in grooves or spaces and by which the screen is held in place.

Mine Shaft Door.—No. 754,268; J. Wineland, Athens, Ill.



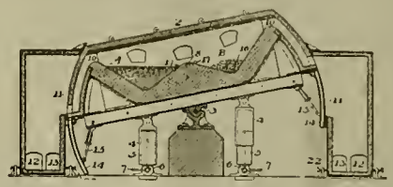
In door for closing elevator shafts, combination with structural framework, of swinging door section hinged to framework, crank arm fixed to each of door sections, pivoted levers having pin-and-slot connection with crank arms at one end and having pin-and-slot connection with vertically reciprocating bracket at opposite ends, and means actuated by raising or lowering of car in shaft to actuate levers and open or close door sections.

Roasting Furnace.—No. 754,199; S. D. Craig, G. E. Kelly and W. Turner, Laharpe, Kans.



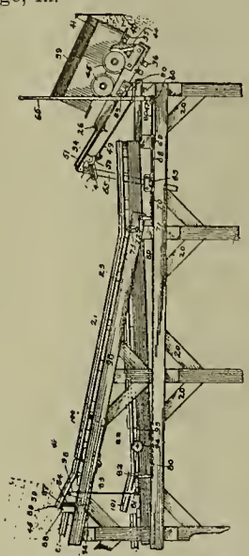
Furnace comprising long casing having inclined floor, track rails on floor, carriage mounted on rails, frame mounted to swing on carriage, two sets of scraper plates arranged on each end of swinging frame, plates of series at ends being at reverse angles, and plates at one end being at reversed angles to plates of other ends, means of holding plates at one end in lowered position while holding plates at other end in upper position, and means for reversing positions.

Method of Treating Ores, Mattes, etc.—No. 754,159; J. A. Potter, New York, N. Y.



Method of treating metal and metal-bearing materials, consisting in forming molten metallic bath upon one portion of furnace hearth, preheating separate charge of solid materials upon another portion of furnace hearth, pouring molten bath over solid material, preheating another charge of solid material upon that portion of hearth from which molten bath was poured, and then pouring bath back upon subsequent charge of solid material, and so continuing.

Automatic Blocking, Releasing and Dumping System for Tram Cars.—No. 753,917; C. J. Ringstrom, Chicago, Ill.



Combination of forwardly inclined and rearwardly inclined track, of rocking bar pivotally secured longitudinally under one of rails of forwardly inclined track and provided with upward extension at each of its ends, roller journaled on upper end of each of extensions, rail sections pivotally secured at one of their ends and located to align with rails of track and connected together, one of sections resting on rear extension of rocking bar, another rail section pivotally secured at its rear end and resting on front extension of rocking bar in alignment with one of track rails of forwardly inclined track, rail section pivoted at one of its ends and in alignment with one of rails of rearwardly inclined track, means to support connected rail sections in raised positions, and connection uniting means and rail section on rearwardly inclined track so that when section is depressed supporting means will be lowered.

New Use for Carborundum.

A new and interesting use has been discovered for carborundum, which has already found large employment as a substitute for emery, says the American Manufacturer. Capable of preparation only in a powerful electric furnace, where silica and carbon are fused together in presence of sawdust and common salt, carborundum is highly refractory; and it has been observed that a thin layer of the same substance applied to any other material of which furnaces are usually constructed protects it from the heat and renders it almost equally refractory. Finely powdered carborundum is made up into a paste with water glass, i. e., sodium silicate or some similar binding substance, and the paste is applied by means of a brush or otherwise to the bricks which are intended to be used for building a furnace, or those bricks are actually immersed in the viscid liquid for a certain time. If the furnace has already been built the paste can be painted on to the exposed surfaces, giving one or more coats, as may be desired. It is stated that a layer 2 mm. thick will protect the bricks from the attack of highest temperature which is ever produced by combustion methods in ordinary work. Examination of the bricks in such a furnace has shown that they had not suffered in the least.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ARKANSAS.

Marion County.

The property of Jones & Gilchrist, adjoining the Jack Pot mine at Yellville, has been added to the shipping list. This mine has been developed with a drill and a shaft has been sunk, proving the correctness of the drill report, says the Record. The shaft is down 50 feet and in ore similar to that of the Jack Pot.

ALASKA.

A. C. Clark, developing mines in Kayak section, says that at least thirty new well-drilling machines are being arranged for that field, besides machinery for beach gold mining at Yakataga. Supplies and machinery for Yakataga go in via Kayak. About 100 men have gone to Yakataga with dog teams and supplies for early beach gold mining this spring. The winter has been a mild one, the thermometer ranging from 28° to 40° above zero. Only twice has it reached zero, and then for a few hours only each time. About 3 feet of snow is on the lower valleys, which is no hindrance to work, though the light snow on the mountain sides is deep. Since November 1st development work has largely been at a standstill, except in the anthracite coal district. French & Campbell, the Alaska Petroleum & Coal Co. and the Alaska Development Co. have kept development work going. Oil development work could have continued during the winter had there been transportation facilities between Kayak island and the mainland. The first oil well struck there continues to flow regularly, and a strong flow of gas continues from the unfinished wells. Five barrels of crude petroleum are being shipped from the Catella oil well to the St. Louis Exposition as part of the Alaska exhibit. They also expect to have an exhibit of coal.

W. N. Matlock and W. M. Beagle, of Pendleton, Or., are arranging to put in a hydraulic mining plant for their mines, near Nome.

The Ketchikan Journal says construction work is progressing on the compressor building for the Alaska C. Co. at Coppermount. Machinists are completing installation of the compressor plant. The sawmill plant has been set in place and work finished upon the mill building. As soon as the work in progress of taking up the water power near the Mellen mine is finished all the works of the company will be operated by water power. An electric light system will furnish light for all the company's workings.

Shakan reports say three marble development companies have been organized in the East to work the marble deposits near there. A sawmill plant owned by one of these companies is on the ground, and a plant for marble cutting has also been received.

ARIZONA.

Cochise County.

G. Clark, of Bisbee, has an option on the World's Fair group, of L. C. Shattuck and W. Grenfell, and the Dubacher-Muheim group adjoining. In the World's Fair group are nine claims, and the Dubacher - Muheim group, three claims. They are 3 miles below Bisbee.

Graham County.

The Santa Rosa M. Co. has been taken over by J. E. Thompson, of Clifton.

Maricopa County.

(Special Correspondence).—S. Taylor, at Cave Creek, is working his claims.—— Free-milling ore is being hauled from the Phœnix mountains to the power arrastra on the Broadway ditch, south of Salt river. The ore is from the claims of J. V. Creatb. —— Development work will be started this week on the New York group of claims, near Morristown.

Morristown, March 13.

The Oro Concentrating Co. has turned over all its interests in the Welcome group of mines, near Wickenburg, to the Rincon M. Co., says Manager Phillips. He is arranging to build a stamp mill on the mine.

Mohave County.

The Altata M. Co. of Chicago, Ill., which has been organized and taken over the Altata mine, near Chloride, has put in a hoisting plant and all water has been removed from the drifts and the mine cleaned of debris to the bottom of the 150-foot shaft. The ore body at the bottom of the shaft has widened to 6 feet, showing mill values. In the drift north from the bottom are 5 feet of ore. In the south drift the same ore is being opened up. In cleaning out the crosscut on this level three veins of silver-bearing ore were shown. On the surface are said to be five veins showing outcrops. The water from the mine is impregnated with copper, and iron buckets left in the mine are soon covered with metallic copper. It is proposed to build tanks and recover the copper in the water. The company proposes to put up a concentrating plant to handle the dumps and the lower grades of ore opened up in the mine.

Machinery is being added to the equipment of the Minnesota-Connor mines, near Chloride, in the mill for crushing and handling the harder ores.

W. H. Cushing of Topeka, Kan., president of the Stockton Hill M. Co., operating at Stockton Hill, near Cerbat, says it is proposed to put in a magnetic separator plant to separate the zinc from the lead and gangue. The company is working a few men on the mine and sinking will be resumed. M. Hughes is superintendent.

At the San Cloud mine of C. T. Kennan, near Signal, near the Yavapai line, work is progressing. Eight miners are on development. The mill, concentrator and cyanide plant will be finished by April 10. The mill will be one of five 1000-pound stamps and five more will be added later. The engine and machinery have been placed.

Owing to inability to get oil, the C. O. D. mine, at Stockton Hill near Kingman, has reconverted its furnaces into coal burners. The work of unwatering is still going ahead.

The Premier Con. M. Co., of St. Louis, Mo., has bought the Rattan-Ruth mines, in the San Francisco mining district, near Acme, and is preparing to remodel and add to the plant on the river for the reduction of its ores. It is proposed to make the mill of 100 tons daily capacity. A cyanide plant will be put in to handle tailings from mill, while an electric plant will be built for power purposes. A railroad connecting mine and mill will be built. The Rattan is opened by shaft to depth of 200 feet and bodies of milling ore opened up. At the bottom there is milling ore.

Pinal County.

(Special Correspondence).—The Troy-Manhattan M. Co., at Troy, has completed the Alice tunnel. They are in 1300 feet. In driving the tunnel a lead of high-grade ore, 14 feet in width, was cut. The Troy-Manhattan Co. is considering building a spur from the Phœnix & Eastern railroad at Kelvin to portal of Alice tunnel, a distance of 6 miles.

The Copper Butte Co., east of Florence, has completed a wagon road from the Gila river to their property. A 40 H. P. boiler and hoist are being set up at the mine. Contracts for several hundred cords of wood have been let.

Florence, March 13.

Santa Cruz County.

The American I. Dev. Co. has taken over the Mowry mine and other lead veins in Tyndal district, near Nogales, and will start operations. J. N. Curtis is manager. He is putting in two pumps to unwater the mine.

Yavapai County.

Manager L. Blakely of the Ramrod mill, in Weaver district, near Octave, says he has milled 500 tons of ore from the Ramrod mine. It is proposed to cyanide the tailings, which contain $10 gold per ton. The ore milled carried an average value of $50 per ton.

Manager Hickey, operating the Malpais group of claims under bond, near the Zonia and Farwell groups, 11 miles from Kirkland, says he is arranging to put up a hoisting plant and other machinery. Development is at a depth of 240 feet.—— Superintendent H. H. Cloud of the Farwell group of mining claims near Kirkland says work is progressing. Work was resumed last month and they have completed 80 feet of underground work, showing ore. A hoisting plant will be put in.

W. W. Lewis of Prescott of the Penn G. M. Co., says as soon as the Poland tunnel has been completed, which will be in June, it is expected the company will resume operations at the Mud Hole mine in Walker district.

It is reported the capacity of the United Verde smelter, at Jerome, will be increased from 1250 tons per day to 1750 tons by addition of a 500-ton furnace. The payroll contains names of 1000 men and more are to be added. Near the smelter a brick building is going up to be used for saving the gold and silver values that pass off in the smoke and dust from the furnaces. It will be connected with the smokestack of the smelter. The company has built a smelter on the Equator mine, 6 miles south of Jerome, and will blow it in as soon as a supply of fuel is at hand. The plant was finished about a week ago and is expected to be in operation within a week. The tramway connecting the mines and plant is in operation.

F. A. Davis of Prescott, who has taken over the Easy Boss mine in Copper mountain section, will start operations on development this week. The Arizona G. & C. Co. has been incorporated and the mine renamed the Heart of Arizona. It is intended to sink the shaft to a depth of 500 feet before doing any drifting or crosscutting. The shaft is down 85 feet. The mine is 4 miles from Mayer, making it easy of access to railroad transportation.

Yuma County.

(Special Correspondence). — Cinnabar has been found east of Ehrenburg, near the old camp of Plomoso. Samples have been shown carrying a fair percentage of quicksilver. The vein matter also carries chrysocolla, and was worked years ago by a French company for copper, the cinnabar being considered as red oxide of copper. A limited amount of development has been done.

Quartzsite, March 13.

CALIFORNIA.

Amador County.

At the Defender mine, at Defender, the mill continues in operation. It is expected to resume sinking. The mine has been opened to depth of 350 feet.

Butte County.

Manager Chittenden of the Golden West M. Co. has additional mining machinery on the ground for the company's mines at Lumpkin, near Oroville.

Calaveras County.

Reports from the Del Monte mine, near Railroad Flat, east of Mokelumne Hill, show the main tunnel was driven 64 feet during month of February, at a cost of $17 per foot. The mill was run on clean-up ore from the upper levels.

The Veith placer mine, near Mokelumne Hill, has been bonded to J. L. Green for two years. Work will start this month.

A strike of ore is reported made last week in the 1050-foot level of the Royal Con. mine at Hodson. A ledge 40 feet in width was opened up.

The forty stamps at the Carson Creek mine, south of Angels, were started last week, rock from the dump being used. The work of opening the old shaft will be started next month. Fourteen men are employed.

El Dorado County.

It is reported that a body of free milling ore has been opened in the Karolyi (formerly the Lady Emma) mine, 1 mile east of Kelsey, and the 10-stamp mill will be put in operation.

The New Highland G. & C. M. Co. has been granted a permit by the California Debris Commission to carry on hydraulicking at the Mameluke Hill mine, adjoining Georgetown. Men are laying pipe and water will be turned on this week. ——The Ancient Channel M. Co. has been incorporated by J. K. Phillips, F. J. Juchter, W. M. Cubery, G. R. Read and E. Johnson, all of San Francisco.

Work at the Witmer & Fuller mine, near Placerville, has been suspended temporarily, pending repairs to the shaft, preparatory to resuming sinking. The concentrates are being shipped.——Operations have been resumed at the Whim mine, near Brownsville, under direction of G. Estey.

Inyo County.

H. J. Lent and O. H. Hill are opening up a deposit of merchantable slate in the foothills 3 miles from Laws, says the Bishop Register. The deposit covers full area of the mining claim, 600 by 1500 feet. It is accessible by wagon road, which will assist shipping. The owners will sink a shaft 50 feet to get below the weathered surface material.

Kern County.

The annual report of the Associated Oil Co., operating in Kern county fields, and also at Coalinga, Fresno county, shows that the total sales of oil for the year ended December 31, 1903, amounted to $2,347,799; transportation cost, $1,226,200; value of oil on hand January 1 was $120,775; production expense, including repairs to improvements, buildings, etc., $339,714; administration expense, $57,536; oil purchases, $94,175. The production of the company has been increased during the year by 7000 barrels per day.

Mariposa County.

During month of February a total of thirty mining locations were filed in Mariposa county.

A bond on the Mountain King, Calendar, Whiteman's, Spring Hill and Mary mines, near Mariposa, has been given to H. C. Austin for $40,000. He will develop and operate them.

Nevada County.

The company of local men opening the New Eureka quartz claim at Canada Hill, near Nevada City, have started a new tunnel to tap the shaft at depth of 115 feet and 30 feet below the present tunnel level. They have been troubled with more water than the pump could handle.

The decision in the case of O'Brien vs. the Grass Valley Con. M. Co. was rendered last week in the Superior Court at Nevada City by Judge Nilon in favor of the plaintiff and puts O'Brien in full possession of the Green Mountain mine.

E. L. Labadie of the American R. & D. Co. of Grass Valley has a bond on the Hartery, Winfield Scott, South Extension of Hartery, Minnesota, Crœsus and Crœsus Extension, near Grass Valley, besides the Edison-Ancho mines of Graniteville.

At the Green Mountain mine, near Grass Valley, a number of improvements and changes will be made, the principal one being temporary abandonment of the Centennial, which the company has bought. The Centennial will be developed through the Green Mountain shaft. The Centennial has been unwatered and the vein examined. Surveys showed the bottom of the Green Mountain shaft to be lower than the Centennial. It is intended to run a drift south of the Green Mountain shaft to intersect the Centennial vein. The distance to be driven will be 400 feet. The mill of the company being on the Green Mountain, it will save construction of another, which would be necessary if the Centennial was worked through its own shaft. Water is in the Green Mountain shaft, and this has interfered with work. Another pump will be put in.

Bonney & Hurst, opening the Elsie mine on Rock creek, near Arbogast ranch, on Selby Flat, near Grass Valley, report progress. They are drifting on the 100-foot level north and south, and stoping out ore from the 2-foot ledge. The Huntington mill is running steadily during the day shift.

W. Bawden et al. of Grass Valley have a lease on a lead which runs through the Weed property, on Alta hill.

The 23-stamp mill at the Blue Tent drift mine, near Grass Valley, is in full operation, says Superintendent C. Graham. The mill is driven by water power under 650-foot head. A mile of steel pipe conducts the water from the reservoir to the wheel. Side-dumping cars of one-ton capacity are used. They dump automatically into the upper ore bin which holds 200 tons, from where the gravel is drawn through gates over grizzlies. It then drops into a 200-ton bin from which it is automatically fed to the batteries, and passes over amalgamated plates. Gravel is being taken from the first raise in the bedrock tunnel at distance of 1100 feet from the mouth. The two main gangways and a crosscut are being driven.

Plumas County.

Three shifts are steadily at work in the Wild Boar mine, near Quincy, seventeen men being employed in running an incline to strike bedrock. A large volume of water has been struck, making progress slow. A 4-inch pump is handling the water.——H., C. & A. Hewett and F. Talley have started hydraulic operations in their mine on Hopkins creek.——Men are at work in the Bunker Hill mine. A raise of 50 feet ahead of the first raise has struck gravel, with the bedrock pitching into the hill.——Superintendent J. Drumgold has started up the hydraulic mine owned by Donohue & Metcalf, at the head of Nelson creek.——The Colonial M. Co., on Nelson creek, has begun operations in its hydraulic mine. W. Spencer of Gibsonville is superintendent.

San Bernardino County.

W. Osborn, manager of the Arum mines, at Vanderbilt, has started development of the Irish-American group of mines south of Java, west of Needles, on which he has a bond.

San Diego County.

The Ranchita mill, near Banner, started crushing ore from the mine last week. C. J. Couts is owner. A 2½-foot paystreak has been opened, avoraging $50 per ton.

At Escondido the Cleveland-Pittsburg M. Co. has bought eleven acres adjoining the mine on the south. The stamp mill of the company started up again last week. Three hundred tons of ore are on the dump.

The lithia mines at Pala will renew operations of mining and resume shipments to the East.

Santa Barbara County.

The Graciosa Oil Co. reports its first well on its land in the northern part of Santa Barbara county, near Santa Maria, continuously flowing. A 2000-barrel tank has been filled from it in five days without pumping, the gravity of the oil being 28°. The company has a contract with the Pacific Oil & Transportation Co. to take the petroleum at 85 cents a barrel. The principal owners of the Graciosa are H. J. Crocker, M. Casey, B. Liebes and L. Phillips of San Francisco. The importance of the result to the general oil industry is that it has demonstrated the wisdom of deep boring for oil, says the Chronicle. The Graciosa property is 12 miles south of Santa Maria and 6 miles from the line of the Southern Pacific Railroad. It consists of 7000 acres under lease. The company took up the Harris ranch, and the Careaga ranch, adjoining,

was leased by the Western Union Oil Co. The latter began sinking wells and now has seventeen finished and producing from 700 to 1000 barrels of oil a day of gravity from 20° to 22°. Petroleum of this gravity was obtained at a depth of 2000 feet. The managers of the Graciosa sank four wells, but, though they reached a flow of light oil at 2000 feet, they continued one well down to the 3000-foot point, where they struck petroleum of 28° gravity. The second well on the Graciosa is down 700 feet and is expected to reach 3000 feet before May 1, and machinery for a third well has been ordered.

Siskiyou County.

A dredger will be built in the Klamath river for working the Garvey Bar mine, above the mouth of Humbug creek, near Gottville, says Superintendent La Schell. Garvey Bar is between the Pacific, McConnell, Kanaka, Swiss Bar, Centennial, Fort Jones and other river claims below and the American Bar and Ash Creek above.

W. E. Baldwin with Angels men has taken over the Finley & Johnson mine in White's gulch on Salmon river, near Etna. The vein is small and high grade. White's gulch is between Eddy's gulch, where are the Gold Ball and other properties, and China gulch, containing the Advance and Music groups. Besides the Finley & Johnson, the Lanky Bob, Swain, Newseme, Cleaver and Blaisicnz mines are on White's gulch.

The Cherry Hill M. Co. intends putting up a quartz mill at its group on Cherry creek, near Fort Jones, directly in front of its tunnel, to be run by electric power from the Siskiyou Electric Power Co. The mine will also be lighted by electricity and the drills operated by the same power. The ledge is 4 feet wide.

Work has been suspended at the McKinley quartz mine on Humbug creek, near Hawkinsville until April 1st, on account of 3½ feet of snow preventing operations.——The owners of placer claims throughout the county are cleaning out the gravel and debris sluiced in during the heavy freshets from late rain storms, and expect to start taking out gold dust, as there is an abundance of water for ground sluicing, hydraulicking and box sluicing.

Work has been resumed on the Mount Vernon quartz claims at the divide between Greenhorn and Cherry creeks, near Fort Jones.——Work was started last week in the Spengler claim, at the mouth of Humbug creek, near Hawkinsville, with A. Smith as superintendent. There will be considerable ground sluicing carried on for some time in removing the surface ground.

Trinity County.

At Dedrick the Mason & Thayer mine will put on men and resume work.——The Globe mine will start up this week, says Superintendent H. Ramdohr.——It is reported the Chloride will resume operations this month.

Tuolumne County.

The mill at the Duffield mine, near Carters, is in operation.

The App mine at Quartz, which has been closed on account of the strike, resumed operations last week with a few men.——J. Barry and E. Sharp of Stent have bought the Brown Bird mine, 2 miles from Stent, alse the Josephine mine, in the same section.

C. Sawyer of San Jose, who has a bond on the Doyle ranch gravel mine, near Columbia, proposes putting a mill on the property to crush the cement gravel prior to washing it.

At the Jumper mine at Stent the 80-stamp mill is running on ore raised to the surface through the Jumper shaft from both the Jumper and Golden Rule ground. A circular saw, used in making wedges out of waste timber, has been set up in the sawmill. A power drill sharpener, operated by compressed air, is in operation. New auxiliary steam heads have been attached to the generator engine and exhaust pipes for saving steam have been set up in connection with the auxiliary plant.

The canvas plant formerly used at the Confidence mine has been bought by the Black Oak M. Co. and will be put in at the Black Oak mine, near Soulsbyville. This plant does not require sweeping, being washed off with a hose.——Sinking is in progress at the Over mine on Saw Mill Flat, 2 miles southeast of Columbia. The shaft is being put down from the tunnel level, 1100 feet from the surface, and is down 60 feet. Sufficient gold is being obtained to pay expenses of the development work, says the Magnet. Pownall & Conlin are owners.

COLORADO.

(Special Correspondenco).—The water supply for the coming summer is causing uneasiness on the part of seme of the mine and mill operators throughout the State. The snowfall has been below the average in most sections. A large number of mills depend on the streams for power as well as for use in the mill. State Engineer L. G. Carpenter reports on the Cache la Poudre the snowfall is about normal; on the Grand river it is about one-half the usual ameunt at this time of year. At the head of the Platte it is light and on the Arkansas and tributaries it is light, running from 40% to 60% of the amount ordinarily found at this season of the year. There is, however, a larger amount of ice in the streams, some of the streams being entirely frozen up. He says that while the snowfall has been light up to date, the ground was fairly wet in the mountains when the first fall came in September, se that the mountain watersheds are in a condition to preserve water. During the month of April is usually the heaviest precipitation.

Martial law in Telluride district, San Miguel county, has been declared at an end. No further serious trouble is anticipated. During the past week affairs have been unsettled and unsatisfactory in Cripple Creek district. The Federation has called out all the lessees. Some of the lessees have been shipping ore to the so-called "unfair" mills, and by shutting down the mines it will shut off the ore supply to the mills.

Denver, March 14.

Boulder County.

The Sylvanite Tunnel Co., owned by Omaha, Neb., men, will put in steam and electric drills to drive the tunnel into Magnolia mountain, at Magnolia. The tunnel starts at a point above the Marchioness tunnel, near the level of Boulder creek. It has been driven for 300 feet. When completed the tunnel will be in about 6000 feet.

The Sparkling Jewel M. Co. has closed down its mine, near Sugar Loaf, to put in a plant of machinery. The company has opened a body of ore at 200 feet, showing 2 feet wide, which Superintendent Culver says runs three ounces gold per ton.

Clear Creek County.

(Special Correspondence).—The tailings plant to handle the tailings from the Newton mill is about completed and will be in operation next week.

Idaho Springs, March 14:

Work will be resumed in April on the Doric tunnel near Georgetown. It has been driven 3009 feet.

Drifting has been resumed in the ninth and tenth levels, west of the Sun and Moon mine, at Idaho Springs. Development work was suspended last October. Last month they resumed drifting east in the two lower levels. A few men are at work in the drift from the Newhouse tunnel, which is being cleaned out and retimbered.——Manager F. D. Wiley of the Chamberlain-Dillingham ore sampler gives the shipments for February at 105 cars, or 2100 tons, against 1520 tons for same month last year.

The Lead lode on Seaton mountain, near Georgetown, has been sold to J. D. Williamson for Denver and Eastern men for $30,000. The ores show gold and silver values.

Chaffee County.

A vein of graphite, 15 feet wide, is reported opened up by the Ethel Hold M. Co., 1 mile north of Cameron, in Turret district. Tests made show the mineral will run 35%.

Custer County.

The following Custer county properties have been consolidated as the Smoky City group, says the Times: Pittsburg, Duquesne, Chartier, Potomac, Monongahela, Pennsylvania, Allegheny, South Pioneer, Invincible. The company is composed of D. D. Moninger, C. P. Becker and E. H. Chase of Pittsburg, Pa. In addition to the above they own the Potomac millsite. They propose to increase work on these claims.

The large volume of water in the shaft of the Toledo mine, near Silver Cliff, is being pumped out by the Bassick G. M. Co., and is being used for steam and other operating purposes at the Bassick mill. A short time ago the Bassick was threatened with shortage of water.

Fremont County.

The New England Con. Oil Co., drilling for oil on Garden park, near Canon City, are 1800 feet deep and have reached the Trenton limestone, says the Times. The company expects to find oil at from 2000 to 2500 feet.

The Copper King F. G. M. Co., F. M. Cooper of Colorado Springs president, reports work will be pushed on a drift at the 200-foet level in the Copper King mine at Dawson, 6 miles from Canon City.

Gilpin County.

(Special Correspondence).—E. W. Williams, manager of the Champion-Trio M. & M. Co., is drifting in the Trio tunnel to connect the same with the 800-foot level of the Champion. Connection is expected to be made by April 10. More men will then be put to work in the mines. The connection will give them good air. Shipments are being made to Idaho Springs and Black Hawk. The Trio tunnel starts in Virginia canyon, on Bellevue mountain, 3½ miles from Central City.

Central City, March 13.

Grand County.

(Special Correspondence).—J. H. Harris & Co. are operating on Grand river, 22 miles from Welcott. They have twenty claims, which they have been working and developing the past five years, and have opened up ore. Assays show copper values. The Moffat Railroad is surveyed through the Red Gorge canyon, in which are these properties. Ore from the Big Dick, on the east side of the canyon, runs 2½% to 7½% copper, and they have also found native copper. Other mines are being developed in this section, but little of importance will be done until the advent of the railroad.

McCoy, March 13.

Gunnison County.

At the May-Mazeppa and North Star mines, near White Pine, the Akron M. Co., owners and operaters, with the 3700-foot drainage and transportation tunnel, after having drained the ore bodies, attaining a vertical depth of 700 feet, shows the veins continuing down, says the Times. They are advancing the main tunnel ahead toward the Eureka, Nest-Egg and Erie mines. Galena concentrates from the ores, sold on controls, show $17 gold, 20 ounces silver and 47% lead, associated with 13% iron excess. At the Eureka, Nest-Egg and Erie mines, adjoining the Akron company, Manager D. C. Tobin of Leadville is extending shafts and levels pending erection of a mill on Galena creek. These properties are owned and operated by the North American P. & M. Association of Denver, which has put in machinery on the Silver Trowel shaft of the Erie group.

Hinsdale County.

R. M. Collins and W. M. Mendenhall, who have been working the Monte Queen and Nellie M. group near Lake City, have leased the stamp mill on the site of the Croeke smelter and will mill the ore which they have broken and stripped during the development of their mines. The ground covered by the Monte Queen and Nellie M. properties is 1½ mile south of Lake City. Collins & Mendenhall have a bond and lease on the Pan-American group in Burrows park, near the Isolde mine and adjoining the World's Fair group, owned by the Dupre M. Co., owners of the Isolde. —— The Hanna M. Co. has begun mining and milling operations. The property is at Capitol City.

La Plata County.

The Neglected mine at Durango, in the east drift, at a distance of 650 feet from the shaft, is said to be showing 4 feet of ore from which a twenty-sack sample gave ten ounces gold per ton. This drift is on the 175-foot level. A raise was made 200 feet east of the new shaft on this level. The management claims the concentrates will average seven ounces gold per ton.

Larimer County.

New York men, with T. R. Countryman of Cripple Creek as superintendent, have begun construction of a copper matte smelter at Pearl. The plant will have daily capacity of 600 tons.

Mineral County.

The ore output of Creede Camp for the month of February was 6000 tons, of which 1400 tons was concentrates from the Humphreys & Solomon mills. There is reported a general improvement in all the mines of the district, more men being at work than during any period of last four years. The open winter has not retarded prospecting and development of outside property. Sinking the three-compartment shaft of the Captive-Inca mine has gone to depth of 500 feet. The Amethyst vein is expected to be cut. The increase of water necessitated a pump, and work is progressing satisfactorily.——The Corsair mine at Sunnyside, near Creede, continues steady output of 600 tons per month. During past two months they have been sinking the shaft for another lift. They are 60 feet below second level, and will start drifting on the vein at 75 feet. They are working twenty-five men, and the number will be increased during coming season. Lessees on the Nelson, which is extension of the Corsair on north, have struck ore, and will begin shipping this week. This mine is owned by F. G. Peck of Colorado Springs, and is being operated by C. W. Stump et al. The Alpha mine, also owned by F. G. Peck, has been leased to S. A. Gardanier, P. Bauer and E. Zender. After extending a raise 50 feet they struck a body of ore, and have shipped sixty tons.

Work on the Nelsen tunnel is progressing at rate of 2 feet a day, and another producer will be added to Creede's shipping list next month in the property of the Little Kanawha, which joins the United mines on the north. The tunnel will reach that ground by April 1. Ore will be taken out through the Nelson tunnel. Arrangements are about completed for sinking the Antlers Park-Regent shaft to intersect the Nelsen tunnel by the time the tunnel reaches that point. Present depth of shaft is 700 feet, and additional 900 feet of sinking will reach the tunnel level.

The lessees on the Monte Carle mine, near Creede, are shipping high-grade silver ore. This mine is on Campbell mountain.——R. S. Light, manager of the Mollie S. mine, is building an aerial tram from the wagon road to the mine, which will be completed by April 1.

Park County.

(Special Correspondence).—The Almaden M. Co. is driving a 1500-foot crosscut tunnel. The veins they expect to open up have produced ore in the upper levels. They have 135 acres. The tunnel is in over 400 feet and two shifts are at work. They will put in a plant of machinery this spring. As soon as the ore body is opened up they will build a mill. The group is in Montgomery gulch above the Peabody placers, 4 miles from Como.

Como, March 13.

Pitkin County.

The Durant M. Co. has taken over the A. J. mine at Aspen and has begun operations, with J. Newman as superintendent. About 20 feet above the seventh level of the A. J., a drift will be started and will be driven through the ground of the A. J., the Spar Con. M. Co. and the Enterprise M. Co. This drift will cut the ore bodies of these properties 285 feet lower than the lowest workings of the Deep Shaft.

Rio Grande County.

It is reported the Golden Income M. Co at Embargo, near Del Norte, propose to put in a 25-ton mill this season. —— The Tornado M. Co., which has a shaft on Ternado hill, will increase development.

San Miguel County.

Work is progressing on the Invincible G. & S. M. Co. mines in Mount Wilson district, says J. A. Ross of Denver, president. The company owns 200 acres of patented ground on Mount Wilson, with a total development of 5000 feet, showing free milling ore. The company has placed a sawmill on the ground, 160 acres of which is covered by heavy timber, from which lumber has been sawed for building a concentrator this season.

Summit County.

The Fair-Stouffer lease on the Gold Dust mine, near Breckenridge, is taking out ore. After doing considerable dead work, retimbering, etc., and then driving ahead several hundred feet, the lessees started to stope on one of the small streaks of ore.——The Germania lessees continue to take out smelting grade ore from the upper tunnel. The ore is said to average 80 ounces in silver, with some gold and from 5% to 6% in lead.——Since completing the air connection by driving the raise of the lower tunnel into the winze from the upper tunnel, Moon, Weaver & Kerse, who are working the Carbonate, are in 18 inches of lead ore that runs in gold and silver. The property is on Mount Baldy, above timberline. ——The 150-foot level of the Old Union M. & M. Co. has been started. The sump below the proposed 150-foot level is completed. From the stope of the 100-foot level lead-silver-gold ore is being shipped.

The Jessie 40-stamp and concentration mill at Breckenridge is running on ore from the lower tunnel. Twenty stamps are dropping. As the water supply increases the balance will be used. The preperty is operated by T. R. Griffith & Co. under an eighteen months' lease. They retimbered and cleaned out old workings to get the property in shape to produce. Concentrating tables are used at the Jessie mill. At the Providence-Colorado group, on the eastern slope of Gibson hill, development is pregressing. The 13-foot vein will supply tennage as soon as the company builds a concentrating plant to handle the product, says Superintendent H. S. Whitehead.

Teller County.

Lessee Duncan et al. operating under lease the Teutonic claims on Ironclad hill, Cripple Creek, have finished putting in a steam plant and hoist. It is intention of lessees to continue sinking until they reach depth of 500 feet. The shaft is down 125 feet from surface. The property is adjacent to the W. P. H. claim.

Equipment of the Homestake cyanide mill on Ironclad hill, Cripple Creek, owned and operated by the Homestake M. & R. Co., will be increased by putting in a 100-ton crusher. With additional tank capacity, which will go in later, this crusher will increase the capacity of the mill to 1000 tons daily. The present capacity is 200 tons daily, but ground is being broken for additional machinery, which will increase it to 700 tons daily.

Three hundred and fifty union miners working in the Midget and Medoc mines, at Cripple Creek, and on various leased properties went on strike on the 12th

inst., having been called out by the Western Federation of Miners, because of shipments of ore to mills and smelters that has been declared "unfair" for failure to grant an eight-hour day. Col. E. Verdeckberg, in military command of the district, has resumed use of the "bull-pen."

IDAHO.

Boise County.

The Lincoln mine at Pearl has shut down owing to large amount of concentrates on hand, which the company cannot haul to railroad on account of poor condition of roads—its storage capacity being limited.

Blaine County.

The Union Standard G. Co. has been incorporated, with principal office at Huron, S. D., to operate near Hailey, by C. F. Heckler, H. L. Moyer, H. E. Crilly, F. Reeder, H. D. Heller, E. L. Sander of Philadelphia, Pa., P. Lawrence of Huron, S. D., and A. L. Sargent and M. H. Lawrence.

Shoshone County.

The three dredgers near Delta are expected to be in full operation the coming season. One is owned by the Mascot G. M. Co., another by the Delta G. M. Co., the third by the Northern G. M. Co. These companies own the lower part of Trail creek and Beaver creek from its junction with Trail to the north fork of the Cœur d'Alene river. The capacity of these dredgers is from 1200 to 1500 cubic yards per twenty-four hours. An estimate of the cost of handling a cubic yard of that ground is 10 cents. The dredgers are equipped with steam power, but later electric power may be substituted.

The Annadora M. Co. has been incorporated at Wallace by R. V. Largent, T. McGowan, L. J. Columbus, W. S. Sites and C. T. Fisher. The properties of the company are in the Beaver mining district.

Ore is reported opened up on the Chester mine, between Big Creek and Osburn, consisting of galena. The vein is 2 feet wide, half of which is said to be galena. The mine is owned by Webb brothers, C. H. Wentz and S. P. Fairweather. The drift from which this ore was taken is 1000 feet long. They will raise to connect with the bottom of a surface shaft.

KANSAS.

Cherokee County.

At Baxter Springs, J. T. McRue of Parkville, Mo., part owner in mines south of Baxter, is increasing work on the Gaines-Brewster tract. He is putting down a shaft where drill holes showed ore. His mine will be known as the Mary Torrance, and is west and joining the Mission mine.——The work of putting in the large crusher plant at the Sunny Side mine is progressing.——T. Goodwin of Ottawa has leased the Mary Buck farm and is putting down several drill holes.

MICHIGAN.

Honghton County.

The strike of the miners of the Copper Range Con. C. Co. mines at and near Painesdale was declared off on the 11th inst., and work is resuming. Changes being made at the Baltic mill are expected to increase its capacity to 2400 tons of rock daily, an average of 600 tons to a head.

At the Centennial mine, near Calumet, they have been sinking under way at No. 2 shaft.

Keweenaw County.

The annual report of the Allouez M. Co., operating at Allouez, shows receipts $115,360, expenditures $102,221. President Fay says the further development of the conglomerate in the first part of the year was encouraging, and a continuance of this work was desired, but so many obstacles were encountered in sinking through sand to the rock in No. 1 Kearsarge shaft, and these so increased the cost that it seemed best to confine their efforts for the present to work at that shaft. The difficulties were finally overcome and since securing control of the water flowing into the shaft the average monthly sinking has been such that it is expected the Kearsarge lode will be reached in the coming autumn. A second shaft will be sunk 1700 feet from No. 1, and this shaft will be started as soon as the snow is off the ground. Superintendent Chynoweth says that since his last report 330 feet of ground have been opened on the Allouez conglomerate on the eighteenth and nineteenth levels, but, although a large part of this ground was well mineralized and gave no indication of decreasing in value, it was decided to stop work at this point for the time and devote attention to the new shaft for reaching the Kearsarge lode, which underlies 640 acres of the Allouez property. The Kearsarge lode has been developed at considerable depth directly south of the Allouez, where it is yielding a large amount of copper, and operations to the north and east of the Allouez on this formation are of the same character. With No. 2 shaft down to the lode and sufficient ground opened up, 2000 tons of rock per day can be furnished to the mill.

MISSOURI.

Jasper County.

In Webb City and Carterville section W. H. Smith & Co., who have been prospecting the Zulu G lots on Center Creek M. Co. land with a drill, are reported to have made a strike of ore last week at 160 feet.——The Premier Lead & Zinc Co., on the Guinn land, north of Webb City, after sinking to depth of 157 feet suspended operations temporarily on account of heavy water. Manager Beckwith states he has set a 3-inch and 6-inch discharge pump in the pump station cut and sinking has resumed.——E. Church & Co., in sinking in the Dunlap shaft, on the Luscombe land, at 170 feet, broke into a lead and jack body in sheet ground. The ground is not so hard but that it can be worked with hand steel. This company has six lots adjoining the Blue Wing and the Osage, which are producers. They expect to have a mill built as soon as they get the ground in shape.

The Preble Zinc Co. of Joplin has been incorporated by G. W. Houk, J. Ulrich, J. D. Flory, M. J. Flory and J. H. Cape. ——The Ruby M. Co. on the High Ball lease at Duenweg has started the mill, with S. Pankin of Joplin as superintendent. Last week's turning was 62,000 pounds of blende and 37,000 of lead.——J. Dinkelhihler is opening two new mines on the Dinkelhihler lease of the Joplin district. The Ivanhoe M. Co. on said lease has overhauled its machinery.

MONTANA.

Fergus County.

The Barnes-King M. Co. at Kendall continues steady work and production. The tank capacity in the Barnes-King has been increased by the addition of an ore tank 32 feet in diameter and 6 feet deep, which has a holding capacity of 210 tons. It will increase the daily capacity of the mill 30 tons. Among other improvements at these mines the hoist house has been completed and the ore bin at the mill has been increased in capacity, holding 200 tons. In the Barnes-King mines the bottom of the incline shaft is 400 feet below the apex of the ore. From the 200-foot level the incline is down 120 feet and is in ore all the way. Ore for the mill is being taken from the open cut and the 100-foot level. Timber for the Barnes-King mines is being cut on Deer creek and other points in the Judith range. The mines have ninety-five men on the payroll.

Jefferson County.

The property of the Overland Con. G. M. Co., in the northern part of Jefferson county and near East Helena, consisting of the Overland claim, the Gold Bug quartz claim, millsite and water rights on McClellan creek, have been sold at sheriff's sale to Caird & Hawksworth of Helena.

The Basin Comstock M. Co., composed of G. W. Brandon, C. Sturtevant, W. A. Kidney and A. S. Ray, the last named being manager, continues operating its group of claims in the copper belt in Cataract district, near Basin. The Comstock Co. has been working continuously on the Boulder Comstock mine the past eight months. A shaft has been sunk on it 315 feet, where a ledge of concentrating copper ore has been opened up. The company intends to put in heavier machinery and sink the main shaft 300 feet farther, and on completion of that work a mill for the concentration of the ores will be built.

Madison County.

The Champion mine, adjoining the Watseka mine, near Rochester, has struck shipping ore on the 250-foot level, and as soon as the surface water recedes sinking to the 500-foot level will begin. Twenty-five men are at work in the mine, drifting and crosscutting, under the management of E. Hand.——Crosscutting continues at the Big Bonanza mine, near Rochester. Sinking will begin again and will be taken to the 400-foot level. This mine is also under the management of E. Hand.

Teton County.

The Belly River Oil & Improvement Co. has been incorporated, with the main office in Shelby, by C. M. Webster, S. H. Wood of Great Falls, W. Dawes of Shelby, H. Beaupre, J. A. Kennedy, P. Younck and J. H. Boucher.

NEVADA.

Humboldt County.

High-grade ore is reported opened up in the James Fraser mines, in Down Valley district on the border of Humboldt and Washoe counties, north of Reno.

Douglas County.

A deposit of topaz is reported found near Lake Tahoe.

Lincoln County.

(Special Correspondence).—The Searchlight M. & M. Co. is down 250 feet in the working shaft, and expects to reach water level this month.——A bond for $40,000 has been taken on the Black Hawk group, consisting of three claims, by J. N. Williams of Boulder, Colo., with J. M. Yates as manager. Work has started.

The second level has been reached on the Pompeii mine, with encouraging results.——Work on the Cyrus Noble mine is temporarily closed. They expect to put up a mill this summer.

The New Era M. Co. will have its 10-stamp mill completed this month.——A crosscut has been made from one of the Empire tunnels at Newberry mountain, and the ledge was found 21 feet wide. The tunnel is in 110 feet, at depth of 100 feet from the surface, and in high-grade ore.

Searchlight, March 12.

The Southern Nevada M. Co. is preparing to put in a 100-ton cyanide plant at Searchlight to treat its stamp mill tailings.

Additional machinery is on the ground for the Quartette M. Co. at Searchlight, including an electric plant. A power house will be built west of the mill. A pumping plant is also to be set up. A triplex station pump will be placed on the 700-foot level and a Cornish pump will be used for sinking. Both pumps will be operated by electric motors. Ten tons of cement will be used for construction of the mortar blocks for the ten additional stamps which will be added to the mill. To increase the water supply a series of 14-foot settling tanks will be set up above the mill.——The Cyrus Noble mine has resumed operations after a brief shutdown. A drift and upraise are being run on the 300-foot level.

At Camp Duncan, near Searchlight, the Dupont tunnel is in 220 feet and is showing values. The tunnel is being run not only to tap the main east and west lead, but also the intersection of the north and south leads—three in number. During the last four years Dupont has made several shipments of ore from them.——Work is going ahead on the Peek-a-Boo tunnel, and on the O. K. a shaft is being sunk.——The Empire Co. has begun operations on the Woods mine, doing preliminary work preparatory to sinking. E. K. Woods is superintendent.

Storey County.

A plant is being built at the Morgan mill on the Carson river, near Virginia City, for working slimes, says Manager Rand. The Comstock M. & M. Co. has sold Rand 10,000 tons of slimes, which are said to carry values of $5 to $6. He will use four tanks 26 feet in diameter and 10 feet deep.

NEW MEXICO.

Grant County.

Last week forty men began grading for the foundation of the concentrator for the Burro Mountain C. Co., near Silver City. T. Carter is manager. The mill will be beyond the Sampson mine and midway between that property and the St. Louis, both of which mines are under control of the company. Daily capacity of the concentrator will be 150 tons. It is intended to have the mill completed next month. A new shaft will be sunk on the Sampson, near the end line of the St. Louis.

The Burro Mountain smelter (Johnson's smelter), near Silver City, was blown in this week. Coke is being hauled from Silver City to the smelter. The electric light plant is in operation. About 100 men will be worked on the Virginia mine and smelter. L. Osmer and E. J. Prest have put men at work on their group of claims at Gold Gulch. They are down 75 feet on the Myrtle and will crosscut at depth of 100 feet. A pumping plant will be put in to handle the water, which is giving difficulty.

R. L. Berkey of El Paso, Texas, has a lease and bond on the Robert E. Lee mine, south of Lordsburg, and Superintendent C. M. Berkey is putting in a pump to unwater the mine.

Otero County.

S. O. Smith is taking out ore from the Little Anna mine at Jarilla.——J. Taylor has put men to work on his lead property in Jarilla.——E. A. Hersperger has men at work on the Garnett mine at Jarilla. Shipments are being made. The steam hoisting machinery for the Three Bears mine at Jarilla is being set up.——Culver & Downs are down 200 feet on their mine at Jarilla. Besides indications of ore there are also indications of water, which is as desirable as a gold strike.

Socorro County.

The Dividend M. & M. Co. is building a smelter at Estey City, with an electric copper plant, in which the ores from the company's properties will be tested, as well as to do custom work. O. A. Henninger is superintendent. The company is laying a pipe line to a spring in the Oscuro mountains. This will supply water until they have sunk a deep well at the mill. Development on the claims is said to be showing fissure veins carrying copper. Teams are hauling the ore to the mill. The company is building roads from claims to mill.

The Martin mill at Rosedale is working steadily. The Golden Bell Co. has men at work and considerable prospecting and development work is reported being done in the camp.

OREGON.

Baker County.

In Virtue district, near Baker City, the Emma mine has been working all winter and putting out bullion, says Manager W. L. Vinson. He has made arrangements to enlarge the working plant of the mine and to continue the tunnel, which is in 135 feet. The work is being done by compressed air drills, which will be driven by electricity. Contract has been let for an electric power line from the Rock Creek Co. of Baker City. Vinson also proposes increasing his mill capacity. The mine will be lighted by electricity. Poles for the transmission line to the Emma mine will be started this week.

In Cable Cove district, near Sumpter, the Valley Queen mine has made progress during the winter, says manager T. C. Gray. He expects to increase the plant and double the output. A mill is also proposed.

Arrangements for extending the transmission line of the Rock Creek electric power plant to the mines around Bourne have been completed. From Bourne the line will be extended to all the principal mines in Cracker Creek district. The fuel problem has been a matter of serious consideration on the part of the mine owners, says the Telegram. Fuel is not only scarce and high priced, but the expense of transporting wood to the mills and hoisting works is almost prohibitive in instances. With electric power available the location of a mill or hoist will not have to be made with reference to fuel supply.

Full operations are under way at the Columbia mine, near Sumpter, on the 700-foot level. The management of the Columbia is also developing under contract the Taber Fraction. Operations on that mine are carried on through tunnel No. 1 of the Columbia.

Grant County.

Manager C. L. Cox is preparing to start operations on the Buffalo mine, near Granite. It is intended to extend the crosscut on lower level to the Buffalo vein which is expected to catch in the next 50 feet. Cox is working his Olive Butte group, near Alamo.

Douglas County.

E. Jenks, owner of the Arrastra and Baltimore groups of mines near Bohemia, says there has been considerable work going on in the district this winter, notably on the Vesuvius group, the Crystal Con., Bohemia group and North Fairview group. The Crystal Con. Co. has been working all winter and has its 5-stamp mill ready to run. The Oregon Securities Co. operations have been shut down since January, but it expects to resume development work this month. The company's Musick mine is blocked with ore, which can not be put in the dump on account of the snow. It has a 30-stamp mill ready to run and room for twenty stamps more, which will be added in the spring.——The North Fairview Co., which has its office in Eugene, has also been working. The Bohemia Co. has continued to drive. It has from 1200 to 1500 feet of tunnel on its group. Superintendent Jenks says, besides the extra twenty stamps to be added to the Oregon Securities mill, preparations are being made for a mill on the Vesuvius and Oregon-Colorado mines during the coming summer.——Trains on the railroad from Cottage Grove to the mines are making one trip a day regularly (except Sunday). The last bridge has been completed and the road will be built farther on into the mines.——Besides the companies mentioned, there are a number of individual claims which have been worked by their owners.

Corvallis men have organized the Twin Rocks G. M. & M. Co. to operate in Bohemia district. The directors are L. and W. B. Hartley, Wallace Hartley, S. R. May and G. B. Spitler. The property of the company consists of nine claims with free-gold prospects.

Jackson County.

M. P. Ward of Portland, part owner of the Millionaire mine, near Gold Hill, says he is increasing the number of men at work. It is the intention of Ward and associates to carry on work and build a plant this season. The property is free-milling and a stamp mill will be put up.

SOUTH DAKOTA.

Lawrence County.

The Trent M. Co. is working men on its group near Carbonate camp, having

started a new tunnel. The Trent grouud is near the Iron Hill mine.

The Deadwood Standard G. M. Co., operating in Ragged Top section, near Lead, will build a wiro rope tramway for delivery of oro at its mill. Additional ore bodies have been opened up. Tho company's cyanide mill is ready fur operation.

Tho cyanide plant at the Buxton and Big Bonanza mines, near Terry, is in operation, handling eighty tons of ore per day. The plant is operated by electricity. The aerial ropo tramway is run by electricity, delivering ore from tho Buxton mine. It is 1200 feot long and crosses Novada gulch. Ore from the Big Bonanza is convoyod to top of mill in cars. The Buxton and Big Bunanza minos are owned by J. Lundborg, J. V. Dorr and A. D. Wilson.

Development is progressing by the Globe G. M. Co., on its group in Nevada gulch, near tho Homestake mincs. They are drifting west from the bottom of the shaft (500-foot level). Surface improvements include hoist with capacity for 1200 feet, air compressor, machine drills, pumps, sawmill, etc. Power is furnished hy gasoline ongines, of which the company has five.

It is expected the additional stamps being installed at the Amicus mill of the Homestake M. Co. at Lead will be in operation by June 1. A portion of tbe macbinery is in place, and work of enlarging the cyanide plant is well under way.—— Tbe additional machinery for the Hidden Treasure G. M. Co. on upper Deadwood gulch, near Deadwood. is in position, and sinking will be resumed in tbe shaft. Tbe plant consists of a gasoline engine, designed to operate a dynamo, by which lights will be furnished about the works and electricity generated for running an olectric drill. The shaft has been started from a drift level at 150 feet below surface, whore a chamber has been cut 35 feet in height. Gasoline machinery will be used for sinking this shaft for several months until a steam hoist is put in. The steam hoist plant will go on top of the hill, directly over the present shaft, from which a raise will be made, says W. Lawlor, superintendent.

UTAH.

Carbon County.

The American Rubber & Asphaltum Co. of Chicago, Ill., bas put in plant of machinery at the Pariette gilsonite mines, 100 milos northeast of Price, and on edge of the Uintah reservation, besides timbering the main shaft of the Pariette down 300 feet.

Juab County.

Preparations are being made for starting the 40-ton cyanide mill in Clifton mining district, says Manager Chipman. For a year past efforts have been directed towards development of the mine. During last run of mill, which was closed down, due to scarcity of water, $10,000 was cleaned ı p, extraction running 90%, with average value of heads $20 per ton. The water problem, Cbipman states, has been solved. The Midas mine is 25 miles west of Fish Springs, and near Canyon Station.

The Gemini mine at Tintic, near Eureka, is producing an average of twenty carloads of ore per week, the heaviest output attained since the fire, which caused a suspension of operations.

The pay of machine men and muckers at the Gemini mine, near Eureka, has been increased 25 cents per day, making the former $3 per day and the latter $2.25, says Superintendent McChrystal. About 100 men are on the payroll of the Gemini.

Salt Lake County.

C. L. Dignowity of Boston, Mass., delivered a lecture to the students of the Mining Club of Harvard at Cambridge, Mass., on March 3d. His subject covered "The Great Bingham Mining Camp of Utah," in which he showed how its ores existed, how they were mined and reduced to metallic form, and what development had taken place there within a few years, changing its output from a silver-lead to that of copper and gold, showing the camp to be annually yielding 800,000 tons of ore, a total yearly profit equal to 10% upon $50,000,000 valuation.

Work has been resumed at the Galena mine at Bingham, and the shaft, which is 235 feet deep, will be driven down to the 500-foot level, from which station prospecting will be started.

The Ohio C. Co.'s mill at Bingham has resumed operations on its second-class product. The first-class ore is shipped to the valley smelters.

Tooele County.

The output of concentrates continues from the Ophir Hill mines and mill of W. A. Clark of Butte, Mont.

It is reported the management of the Buckhorn mines at Ophir proposes building a tramway at the mine for transportation of ore.

WASHINGTON.

Ferry County.

Reports from the Moteor, on south half of the Colville reservation, says mining wurk is progressing in that camp. The tunnol being run into east side of Stray Dog canyon is going ahead. It is proposed to crosscut ledgos, the farthest away of which is 1 mile from portal of tunnel. Tho Several is being worked at 250 feet in depth and is shuwing ore. The White Swan has comploted a tunnel which crosscuts the east and west ledge. ——The Whito Rose has increased its equipment.——The Meteor, the Dead Shot and the Raspberry, besides a number of other properties, are proparing to resume operations.

Franklin County.

The Pasco Fine Gold Co. is putting up a 5 H. P. ongine, with other machinery, including several hundred feot of 6-inch hose, for extracting gold from the black sands, at Pasco. Experiments are said to bave been successful.

FOREIGN.

AFRICA.

Congo Free State.

Engineer Adams, for the Tanganyika Concessions, operating near Kambove, reports developments on the Ruwe Gold Hill mine in Katanga are satisfactory. Each of the three shafts being sunk along course of reef for length of 800 feet have entered the gold-bearing standstone, and it is found to be regular. Shaft No. 1 is 47 feet, No. 3, 41 feet and No. 5, 42 feet in depth, giving backs on dip of 100 feet. Free gold and gold-bearing sulphides are shown. Adams further reports he is prospecting surface dirt near outcrop and has sunk fourteen holes to hardpan (about 2 feet) for a distance of 445 feet, and 3500 pounds of dirt from these holes panned 3 ounces 17 dwts. 17 grains of coarse gold, besides fine gold and sulphides. Some of the pieces weigh 2 to 6 dwts. At the Kansanshi mine of the company in Northwestern Rhodesia, the report estimates that in reefs D and E above the 80-foot level there are in sight 53,000 tons of ore of average value of 17% copper, 3 dwts. gold and 7 dwts. silver. Of tbe six smaller veins exposed in main crosscut being extended across the mine eastward from shaft E, one vein is 3 feet wide and of sulphide ore assaying 25% copper and 2 dwts. gold.

AUSTRALIA.

New South Wales.

The cost of production at the Central mine, Broken Hill, during the year ended June 30, 1903, is shown by the annual report to be £4 2s 7½d per ton of concentrates obtained, as against £3 14s 8d per ton during the preceding year. The extra expense arose from the "creep" at the mine and the infiltration of water from an adjoining property.

BRITISH COLUMBIA.

Boundary District.

Estimates show 1300 men employed in the mines and smelters of Boundary district, including those directly employed in the ore carrying from the mines to the smelters, says the News-Advertiser. As a number of properties are not now working that are expected to be operated this spring, it is expected the number will be increased.

Mines.	Men.	Wages.
Granby Mines	400	$40,000
Athelstan	25	2,500
Mother Lode	100	10,000
Emma	34	3,500
Oro Denoro	30	3,000
Providence	35	3,500
Elkhorn	14	1,400
Senator	14	1,400
Miscellaneous	50	5,000
Granby Smelter	300	30,000
Mother Lode Smelter	150	15,000
Train crews	150	25,000
Totals	1,302	$140,300

All miners in the Boundary district receive $3.50 per day of eight hours under ground or ten hours above ground, while muckers receive $3 for corresponding time. The railway train crews work longer hours and receive extra for overtime.

The British Columbia C. Co. is adding to its plant and machinery at both its Mother Lode mine, near Greenwood, and its smelter at Greenwood. A second crusher is on the ground. In connection with the installation of this crusher, improvements are being made at tbe mine which will result in more expeditious handling of large quantities of ore. At the smelter the buildings for housing the converter plant are finished. One of these is built of steel, on mansonry piers and covered with corrugated iron. The main building is 45 feet by 90 feet and 38 feet height, and an extension is 30 feet in width and 60 feet in length. The machinery is slow in arriving. The blowing engine is arranged for running by either steam or electricity. The brick sub-station for stepping down the electric current to be received at 22,000 volts is ready for use as soon as tho transformers are received. A brick smokestack 122 feet in beight has been built. J. E. McAllister is superintendent of tbe smelter, with G. Williams construction engineer.

The Chicago-Phœnix M. Co. has been organized in Chicago, Ill., to operate the Nellie Cotton group of claims at Phœnix. Tho Nellie Cotton gruup consists of the Nellie Cotton and Mystic mineral claims, south of tho Knob Hill mine. Most of tho work has been doue on the Nellie Cotton, where there is a showing of pyrrhotite. A machinory plant will be put in and H. J. Cole of Spokane, Wash., will be manager.

The Bruce, near Midway, near Phœnix, has been bonded by F. Keffer, manager, and J. E. McAllister, smelter superintendent, of tbe British Columbia C. Co. at Greenwood, for $50,000, for eighteen months. Considorable development work is done on the property and it has a tunnel several hundred feet in length. It is near the Canadian Pacific Railway, and it is proposed to connect the mine with the railway by a tramway.

The Athelstan Co. is arranging to reorganize and consolidate the Athelstan-Jackpot group in Wellington camp with its holdings. Work and shipments will be resumed April 1.——On the Don Pedro claim, one of the Lake group, being operated by the Chicago-British Columbia M. Co., the contractors for 100 feet of sinking have depth of 60 feet, the shaft being well timbered and sinking being on high-grade ore.

The British Columbia C. Co. has issued a circular to stockholders announcing the abandonment of its plans to consolidate with the Snowshoe mine near Greenwood. It also says improved conditions in the property render failure of the consolidation plan of no great consequence. The blast furnaces are in full operation, with ample ore supplies. Converting and electrical plants are approacbing completion.

Cassiar District.

The coming season is expected to increase operations in Atlin section. The British-American M. Co., with headquarters at Philadelphia, Pa., will have two dredgers in operation. The company last year put in a dredger and intends to start it on Gold Run about April 1. It will also build another dredger on its ground at Tar Flats, 2 miles above Discovery, on north side of Pine creek.——J. M. Ruffner is negotiating an amalgamation of the Pine Creek Power Co. and Stevendyke & Deek's group of leases on south side of Pine creek, above Discovery.——Seattle, Wasb., people have taken over the Con. Spruce Creek placers and has merged it with the Spruce Creek Power Co. They will complete the plant. The Denny-Blaine L. Co., N. H. Latimer, G. B. Gaddis et al. of Monmouth and Avon, Ill., are interested.——A consolidation of interests on McKee creek is also planned, the Atlin M. Co., the Con. M. Co. and the Hawkins-Christopher leases being in the deal. If the merger goes through it may also embrace the Birch Creek Hydraulic Co.

East Kootenay District.

It is expected the St. Eugene mine, near Fort Steele, will be put in operation again next month.

The Nip and Tuck placers on Wild Horse creek, near Fort Steele, owned by D. Griffith, have been leased to a Chinese company. Considerable preparatory work is being done. Pipe lines are being laid and flumes built. This company will operate two giants during the coming season.——A Chinese company will work on the hillside above the Nip and Tuck. They are also making preparations to start piping.——Several Chinese outfits will work the channel of Wild Horse creek, some have wing dams and another outfit will flume the creek near the mouth of Brewery creek, as this ground has never been worked and is too narrow to wing dam, says the Prospector.

Rossland District.

Le Roi Two oil concentrator was closed down last week awaiting arrival of a delayed car of oil, which was held up by a snow blockade in tbe East. The plant is expected to be in full operation again next week.

Vancouver Island.

During month of February the Tyee mine at Mount Sicker shipped 500 tons to the Ladysmith smelter. The average cost of mining and transporting the ore is $2.25 per ton.——During Febraury the Marble Bay mines, on Texada island, sent 3414 tons to the Crofton smelter. Of this 1124 tons were first class ore and 2290 tons were of second class. The first-class ore was from the north stope of the 460-foot level.——The Copper Queen, on Texada island, has joined the list of shippers. It is one of the Van Anda M. Co. claims. G. L. Mackenzie, manager, is increasing development on the group.

Slocan.

The following are total ore shipments from Sandon fur January and February:

SILVER-LEAD.

Mine.	Total Tons.
Ruth	232
Blue Bird	20
Slocan Star	262
Ivanhoe	121
Reco	301
Last Chance	101
Payne	204
Sunset	145
Mountain Con	27
Sovereign	41
Idaho	80
Monitor	20
Cinderella, Medford	120
Total	1,664

ZINC.

Ivanhoe	99
Payne	357
Total	456

The silver-lead and zinc mines around Sandon have sent out so far this year 1500 tons of the former ore and 500 tons of zinc. The shipments of zinc ore have been confined to the Payne and the Ivanhoe. This is chiefly due to the fact that the lead bounty provided by the Dominion Government is now obtainable. The Slocan Star, Reco, Payne and Ruth are the chief producers of silver-load ore. The Star has sbipped 250 tons of high-grade ore, the Reco 300 tons, tbe Payne 230 tons and the Ruth 162 tons. The zinc from the Payne mine has beeu sent to Iola, Kan. It assays 55% to 58% zinc, twelve ounces silver and 5% iron. The ore is free from lime and manganese and is the product of the magnetic separator. Magnets of a heavier type than the ones now in use are being put in in order to bring the ore up to a 60% grade, with 1% iron and from twelve to fifteen ounces silver. The Slocan Star has zinc, but is not sending it out. The Payne mine is reported to have a contract with a company of Halderstadt, Germany, for 2500 tons of zinc. The ore will be shipped in bulk and will comprise most of the year's output of tbe Payne. More men have been added to the number at work at the Ivanhoe mine, there being sixty-five on the payroll.

There will be three reduction works built in the Kooteneys, two will be for zinc and one for lead, says F. Ferneau, of Newcastle-on-Tyne, England. A zinc enriching plant, a zinc reduction mill, and a lead smelter for the reduction of wet ores are proposed. The zinc plants will he started as soon as the snow is off the ground. The zinc enriching plant is to be built by the Monitor & Ajax Co., at the head of Slocan lake, near Slocan City. The ordinary zinc concentrates, which can be turned out of most Slocan mines, will be enriched by maguetic process to a percentage which will stand exportation or treatment at British Columbia reduction works. The location of the latter plant has not yet been decided on. Ferneau estimates that the mines of the Slocan will turn out zinc concentrates averaging 40%. In the enriching mill, the percentage will be increased to 55 and upwards.

West Kootenay District.

The Spokane Falls Placer Co. has been organized to work ground on Lardeau creek, near Trout lake, by A. E. Shepherd, J. P. Mix and J. B. Campbell of Minneapolis, Minn. The company has a five-year lease of ½ mile of the creek and also a water right for hydraulic purposes. It is intended to dam the Lardeau at mouth of the canyon, ¾ of a mile from Trout lake, and from there build a flume which will deliver the tailings directly into Trout lake.

CANADA.

Imports of mining machinery into Canada during 1903 were large, the total value being $1,281,185, says the Vancouver News-Advertiser. Most of the machinery imported was supplied by manufacturers in the United States, the value of tbe imports from this source being $1,206,405, while from Great Britain machinery to tbe value of $61,425 was imported. Great Britain supplied Canada last year with nearly double tbe quantity of wire rope furnished by the United States.

Yukon Territory

L. L. Lane and C. D. Lane, of San Francisco, Cal., and J. H. Conrad of Montana, are reported to have bought the Arctic Chief copper mine, at White Horse, for $80,000. Conrad says tbe property will be worked with more men this summer. Conrad also hought a number of claims on Bullion creek in tbe Alsek district. He will send in men and supplies to work them this year.

MEXICO.

Chihuahua.

N. O. Bagge of Los Angeles, Cal., owner of the Minas de Almaloya, between Jimenez and Parral, and Manager D. W. Shanks report operations going ahead with 130 men in the development of prospects near the Cigarrero mine. On the

San Enrique mine three tunnnls are under way. The upper one will gain depth of 166 feet, the second 280 feet, and the third, which will be, 800 feet long, will give depth of 430 feet. On the Cerro Colorado three shafts are being sunk. The last one started is down 50 feet; auother is down 200 feet, with 100 feet of drifting on the lowest level, and the third has reached 225 feet. They propose putting in additional machinery. It is thought the machinery will be electrical, and a central power plant is proposed. The Mexican owners of the Cigarrero mine are shipping to the American S. & R. Co. 125 tons of ore daily, that nets $40 per ton, Mexican. This is their second grade ore. Last week five cars were shipped that gave 50% lead, and, besides the lead and silver, carries gold. An 8-inch streak in the mine is said to run 3000 ounces silver per ton. The owners have their double-track gravity tram from the two workings completed. Contract for 500 meters of tunnel work, drifts, etc., from the present lower tunnel has been let. The company will build a railroad from the mine to Baca station, on the Parral branch of the Mexican Central, a distance of 5 miles. They are figuring on cost of an electric plant to make it an electric road.

The Barranca del Cobre mines are turning out 300 tons a month of 40% copper concentrates, with gold and silver values, that are shipped out by way of Minaca. Since last September the machinery has been overhauled. Much development work has been done, and every head is in ore, says the Chihuahua Enterprise. The capacity of the plant is fifty tons per day.

Durango.

(Special Correspondence). — The California M. Co. has resumed work on its mines near San Dimas. The last ore shipment was made to Durango a year ago and the mill has been closed since.—— E. E. Hicks of San Dimas has men at work exploring his claim at Chilar. The ore is free milling.

San Dimas, March 11.

Mexico.

An Arizona company has been organized to take over and consolidate the Chihuahua, Primavera, La Chiquita, El Globo and Omega mines, near El Oro. The work, it is said, will be concentrated on the Chihuahua.

El Oro M. & R. Co., at El Oro, reports for month ending Jan. 31, the mill ran twenty-eight days, crushed 9368 tons, producing from 100-stamp mill $111,884 and cyanide plant $7563; working expenses and development amounted to $64,951. Profit from railway for month was $6161. There has been expended on permanent improvements $75,863, including $74,529 on new mill. The manager says the railway profit has been reduced by repairs to engine and expenditure on permanent improvements.

Michoacan.

In central Michoacan a group of copper mines owned by A. J. Peyton & Co. of New York and Mexico City has been steadily developed for the past three years. The group consists of the Santa Emilia, Dona Luisa and La Natividad, six hours' ride from Coapa, on the Morelia branch of the National Railroad. It is at an elevation of 6700 feet and the 473 acres of land are well wooded, having an abundant supply of lumber for timbering and firewood. The water supply is large. At the Santa Emilia mine the shaft is sunk to a depth of 543 feet. Sinking will be continued till 600 feet is reached, when drifting and crosscutting work will be started. While sinking, two veins of red copper oxide were cut in the shaft. On the surface the equipment of the mine included a 100 H. P. boiler and hoist with capacity of 2000 feet. The company proposes to make improvements and additions to the equipment, including a 60 H. P. boiler, an air compressor to give better ventilation, and an electric plant. A second shaft has been sunk near the first and a vein of native copper cut. From this vein several carloads of ore were shipped, but work had to be suspended, due to a heavy inflow of water. At the Dona Luisa mine the Enrique tunnel has been run 396 feet and three veins have been cut, one 3 inches wide, one 6 inches and tbe third 6½ inches wide. The north drift tunnel is run for 160 feet and is kept supplied with air by pumping. Seventy feet ahove the Enrique tunnel is tbe Heath tunnel, which has been driven 550 feet. It is 700 yards south of the Enrique tunnel. At the end of the Enrique tunnel a winze has heen run 150 feet. The Enrique tunnel follows the vein along its entire length and the ore shows 4% copper. Work has been temporarily stopped in this tunnel until compressed air machinery can he put in. In the north drift two veins have been opened, which show copper values, with seven ounces of silver and half an ounee of gold per ton. A third vein shows 5% copper and small values in gold and silver. They propose sinking a vertical shaft, which will be started as soon as machinery is set up. The shaft will be sunk to water level. At 1000 feet higher than the Santa Emil a shaft is the company's La Natividad. A vein of red oxide (cuprite) has been opened, showing 2 feet thick between walls, and is said to have a pay streak of 6 inches of 40% copper.

Sinaloa.

(Special Correspondence). — Timbering is in progress in the Estaca and Descubridora mines at Guadalupe de los Reyes. The mines are owned by a Franco-Spanish company and are the principal producers of Sinaloa. Recently some of the pillars in the mines were worked up, leaving the backs unsupported. Some of the heavier timbers are being cut from the hard woods of the mountains in the lower country and are hauled 25 miles to the mines by oxen. The ores have changed from mostly gold values to predominance of silver.

A company has been organized to work thc Mariposa mine, 2 leagues west of Guadalupe de los Reyes. A mill will be built below the mine on the Arroya de Guadalupe. —— T. Ripperdam, owning several smelting properties near the Sinaloa-Durango line, has bought a site to build a 50-ton smelter at Casala.——The Refugio mine, near the Elota river, is being crosscut at 200 feet. A sample across the face gave returns of twelve ounces silver and $4.13 gold per ton. The vein runs between granite and lime.

Guadalupe de los Reyes, March 10.

Sonora.

The Alsacia mine, 30 miles from Cananea, will be equipped with machinery for development purposes, says C. F. Wren of Bisbee, Ariz., manager. Ore has been taken out of the shaft which is down 80 feet, showing values in silver and copper.

Vera Cruz.

This year the refinery of the Mexican Petroleum Co. at Ebano, near Tampico, will be worked to its full capacity of 800 barrels daily. Until lately the work of the company has been experimental. The product of its sixteen wells that are in operation has been stored in tanks, where it is left to settle. After drawing off the lubricating oil, there remains a residue of asphalt. The greater part of this asphalt is consumed at present in the cities of Vera Cruz and Mexico. The company has completed a railroad 6 miles long, between the wells and the refinery, for transporting men and tools to the wells and returning with oil to the refinery.

Zacatecas.

The San Luis del Oro Co.'s plant, consisting of twenty stamps, 1000 pounds per stamp, etc., and a 50-ton cyanide plant, are in operation. The San Luis del Oro mine is 2 kilometers south of Zacatecas.

NEW ZEALAND.

The total gold returns from dredgers represented about 22% of the New Zealand output for last year.

NORWAY.

On the west coast of Norway M. Christopherson, B. Tibbey, R. Smoot, H. C. Lund, H. Dinwoodey, P. T. Farnsworth et al. of Salt Lake City, Utah, have options on nickel and copper-bearing ledges, and first payment has been made. Manager Christopherson says he has started work of opening up the ledges, which are showing values of 2% to 6% nickel. In one of the ledges an average of 9.5% copper has been obtained. The nickel-bearing vein sbows from 9 to 20 feet of ore, which has been opened up for 130 feet on the strike. For the reduction of nickel ores an electric process is in use in Norway, although the furnaces at Swansea, Wales, are open to a reduction of a concentrated product, the cost of transportation being but $1.12½ per ton, says Christopherson. The same outlet is afforded the copper-bearing ores. W. A. Christopherson is superintendent.

Obituary.

P. D. CARPER, owner of the Good Hope mine at Searchlight, Lincoln county, Nev., died at Los Angeles, Cal., on the 1st inst.

J. C. BUTLER of Denver, Colo., interested in Colorado mines, died at St. Louis, Mo., on the 4th inst. Deceased was born in Pennsylvania forty-six years ago, and graduated from Alleghany College at Meadville.

C. M. BONNEMORT, a mining man of Oakland, Cal., died on the 14th inst. at the age of seventy-one years. Deceased was a native of Massachusetts. He was associated with Mackay, Flood, Fair and others during the early days of the Comstock in Nevada.

Personal.

J. S. CAINE of Bodie, Cal., is in San Francisco, Cal., on mining business.

E. C. ENGELHARDT has returned to Denver, Colo., from Cave Creek, Ariz.

B. F. BROOKS of Weed, Cal., interested in oil properties, is in San Francisco, Cal.

J. BROCKMAN of Los Angeles, Cal., interested in Arizona mines, is in San Francisco, Cal.

C. M. FUELLER of Denver, Colo., has returned there from a trip to Cripple Creek district.

F. L. CLARK of Spokane, Wash., interested in mines in the Northwest, is in San Francisco, Cal.

J. M. BARNEY of Dutch Flat, Placer county, Cal., is in San Francisco, Cal., on mining business.

J. NEWMAN is superintendent of the mines of the Durant M. Co., at Aspen, Pitkin Co., Colo.

MANAGER T. JACOBSON of the Columbus Con. M. Co. of Bingham, Utah, is in Houghton, Mich.

W. H. KINNON of Denver, Colo., is superintending construction of a smelter at Basin, Montana.

R. A. KERR returned to Salt Lake City, Utah, last week, from Toronto, Canada, on mining business.

E. L. LABADIE of the American R. & Dev. Co. of Grass Valley, Cal., has gone East on mining business.

W. OLIVER is superintendent of the Frontera group of the Dwight F. Co., near Mascota, Jalisco, Mexico.

J. J. BURKE, mechanical engineer, of Salt Lake City, Utah, returned last week from a trip to Boise, Idaho.

C. J. PHILLIPS is manager of the Calera mine, near Minaca, Chihuahua, Mex., vice J. W. Phillips resigned.

W. BALLANTYNE of Central City, Colo., is manager of the Mingo group of mines in Lake district, Gilpin county.

G. W. STARR, superintendent of the Empire mine at Grass Valley, Cal., is in San Francisco, Cal., on business.

A. SMITH is superintendent of the Spengler mine on Humbug creek, near Hawkinsville, Siskiyou Co., Cal.

F. A. HAZZARD of Whittier, Cal., is at Santa Eulalia, Chihuahua, Mex., examining mines in which he is interested.

L. S. JUDD of Oak Park, Ill., is in San Francisco, Cal., from Quartzsite, Ariz., where he has been examining mines.

G. W. DORSEY is at Boise City, Idabo, from California, via Salt Lake City, Utah. From there he will go to Lincoln, Neb.

A. H. ELFTMAN, Ph. D., of Minneapolis, Minn., has returned from Park City, Utah, via the Black Hills, South Dakota.

C. K. COLVIN of Denver, Colo., has returned there from Breckenridge, Colo., where he was examining mining property.

L. T. BAKER has returned to Britton, S. D., from a trip to the Gold Bug mine, near Sumpter, Or., in which he is interested.

W. L. WATTS, E. M., has returned to the City of Mexico from an extended trip among the mining districts of Durango, Mexico.

F. F. THOMAS, manager of the Gwin M. Dev. Co., at Gwinmine, Calaveras county, Cal., is in San Francisco, Cal., on business.

R. D. JACKSON, manager of the Santa Eulalia M. Co., at Santa Eulalia, Chihuahua, Mex., is in San Francisco, Cal., on business.

W. C. BOGUE, local manager of the Mine & Smelter Supply Co., Salt Lake City, Utah, has returned there from Denver, Colo.

VAN R. WHITALL, manager of the Hydrocarbon Manufacturing Co., Denver, Colo., has returned there from a trip East.

J. W. PHILLIPS has resigned as manager of the Calera mine, near Minaca, Chihuahua, Mex., and has gone to Denver, Colo.

M. HUGHES is superintendent of the mines of the Stockton Hill M. Co. at Stockton Hill, near Cerbat, Mohave county, Ariz.

E. BAMBERGER and J. A. KIRBY returned to Salt Lake City, Utah, last week from examination of the Gold Ridge mine, near Durkee, Or.

W. W. LEWIS of Prescott, Ariz., of the Penn G. M. Co., returned there last week from a business trip to New York and Philadelphia.

M. L. REQUA, mine owner and president of the Pacific Wire & Steel Co. of San Francisco, Cal., has gone to New York on business.

W. W. LEWIS of Prescott, Ariz., returned there last week from a trip to New York and Philadelphia, Pa., in interest of the Penn G. M. Co.

C. C. MATHEWS, superintendent of the Oregon Securities Co. of Bohemia, Or., returned there last week from New York on company business.

W. F. SNYDER, manager of the Western Exploration Co., returned to Salt Lake City, Utah, last week, after an absence of several weeks.

F. L. ROUDEBUSH has returned to Denver, Colo., from Sinaloa, Mexico, where he has been looking after mining interests for London men.

E. F. ARMSTRONG, managing director of the San Jorge-Minillas M. Co., at Minillas, Chihuahua, Mex., has gone to London, Eng., on business.

W. H. CUSHING, president of the Stockton Hill M. Co., has returned to Topeka, Kan., from the company's mines at Stockton Hill, Mohave Co., Ariz.

P. P. BUSH, general Western manager of the Vulcan Crucible Steel Co., has returned to Denver, Colo., from a trip to the Pacific coast and Northwest.

H. C. BEELER, consulting engineer of the Crœsus M. Co., has returned to Cheyenne, Wyo., from the company's mines near Hailey, Blaine Co., Idaho.

J. M. MEIGHAN, formerly superintendent Mount Jefferson Mines Consolidated, Tuolumne county, Cal., is now located at 175 Crocker building, San Francisco, Cal.

T. R. COUNTRYMAN of Cripple Creek, Colo., has gone to Pearl, Larimer county, Colo., to superintend construction of a copper matte smelter for New York men.

J. F. WATSON, of Portland, Or., has been chosen to fill the vacancy on the board of directors of the American Mining Congress, caused by death of J. T. Grayson.

C. L. BUCKINGHAM, who has had charge of the erection of the new mill on the property of the Bonnie Girl M. Co. at La Plata, Colo., has returned to Denver, Colo.

HORACE F. BROWN, E. M., has gone to Butte, Mont., from San Francisco, Cal., and will also visit the iron furnaces of western Pennsylvania before returning to California.

FRANK KLEPETKO, now of New York, is credited with being offered a high place in the general management of the Anaconda and Amalgamated interests, Butte, Mont.

MANAGER G. SNYDER of the Western Exploration Co., of Salt Lake City, Utah, operating the Balaklala mines at Kennett, Shasta county, Cal., is in San Francisco, Cal., from Kennett.

R. A. F. PENROSE Jr., interested in Arizona and California mines and president of the Commonwealth M. & M. Co., at Pearce, Arizona, is in San Francisco, Cal., from Philadelphia, Pa.

G. W. HOWE, who has had charge of the Levens Ledge mine, southern Oregon, as assayer and chemist, has accepted a similar position with the Home M. Co., near Bakersfield, Kern county, Cal.

F. G. BAUM, formerly assistant professor of electrical engineering at Stanford University, Palo Alto, Cal., has been appointed electrical engineer and general superintendent of the California Gas and Electric Corporation, at San Francisco, Cal., which recently absorbed the Standard Electric Co.

Trade Treatises.

Catalogue No. 60 of the National Electric Co., Milwaukee, Wis., furnishes finely prepared illustrated description of alternating current machinery for lighting, power and railway service.

THE Van Meter continuous system of concentration and separation of minerals hy means of aluminated hydrocarbon concentrating oil, is the subject of a catalogue issued by J. W. Van Meter, inventor, and W. P. Fuller & Co., San Francisco, Cal., manufacturers. Patent specifications are given and cuts show laboratory apparatus for experimental purposes, also details of working plants.

Commercial Paragraphs.

A. E. Blackwood, 42 Broadway, is the New York representative of the Sullivan Machinery Co. of Chicago, Ill.

The Redfield Drill Co., 1606 Blake St., Denver, Colo., have recently shipped one of their band power rock drills to Portland, Or., one to Woodside, Utah, and one to Rockvale, Colo.

Deitz Electric Drill & Machinery Co., 1614 Blake St., Denver, Colo., have orders from the Montgomery G. M. Co., Alma, Colo., and D. R. Patterson, Jamestown, Colo., each for one of their electric drills.

The American Locomotive Co., has bought the Locomotive & Machine Co. of Montreal for $1,500,000, 33⅓% to be paid in cash and $500,000 in 4% bonds. The financing of the purchase will embrace the issue of $1,500,000 of 4% bonds by the American Locomotive Co.

Consolidation of the Bullock Electrical Manufacturing Co. of Cincinnati with the Allis-Chalmers Co. of Chicago is announced. The entire business of the Bullock Co. is taken over by the Allis-Chalmers Co. and the trade of both will be continued as that of a single concern.

Fairbanks, Morse & Co., Denver, Colo., have recently sold three Elspass mills, one for Baker City, Or., one for Golconda, Nev., and one for Chloride, Ariz. They also report the sale of a 15-stamp mill, including engine, boiler, etc., to the Hudson Mining Co., Idaho Springs, Colo.

Latest Market Reports.

San Francisco, March 18, 1904.

METALS.

Silver.—Per oz., Troy: London, 26⅛d (standard ounce, 925 fine); New York, bar silver, 56⅝c, refined (1000 fine); San Francisco, 56¼c; Mexican dollars, 45⅜@46⅛c San Francisco, 44½c New York.

Copper. — New York: Standard, $12.50; Lake, 1 to 3 casks, $12.50; Electrolytic, 1 to 3 casks, $12.62½; Casting, 1 to 3 casks, $12.37½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 15s spot per ton.

The New York Commercial says: The local copper market is stronger, there being a better inquiry both from domestic consumers and exporters. The small volume of business shows that the consuming trade still lacks confidence in the future of the market. The statistical position of copper in Europe favors a stronger market than is at present in evidence. The stocks of copper abroad are light and consumption during the past two months has been going on at a very good rate. Consumers evidently desire to make purchases, but they were met with firmer prices whenever they tried to secure supplies in large quantities.

Lead.—New York, $4.60; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.85. London: £12 ₱ long ton.

Spelter.—New York, $5.10; St. Louis, $5.00; London, £22 5s ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

Tin.—New York, pig, $27.75@28.10; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 31c; less, 32c; bar tin, ₱ lb., 32½@35c. London, £126 2s 6d spot.

Platinum. — San Francisco, crude, $18.00 ₱ oz.; New York, ingot, $19.00 ₱ Troy oz. Platinum ware, 75 @ 82c ₱ gram.

Quicksilver. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ₱ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

Babbitt Metal.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

Solder. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

Zinc.—Metallic, chemically pure, ₱ lb., 50c; dust, ₱ lb., 10c; sulphate, ₱ lb., .04c.

Nickel.—New York, 50@60c ₱ lb.; ton lots, 40@47c.

Aluminum.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

Nails.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4 and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

Lime.—Santa Cruz, $1.25 country, $1.25 city ₱ bbl.

Cement.—Imported, $2.15@2.40 ₱ bbl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ₱ bbl. in sacks, 4 sacks to bbl.

STRUCTURAL MATERIALS.

Iron.—Pittsburg, Bessomer pig, $13.60 @13.85; gray forge, $12.60; San Francisco, bar, 3c ₱ lb., 3½c in small quantities.

Steel.—Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ₱ lb.

Caps.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

Fuse.—Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

Candles.—Granite 6s, 16 oz., 40s., 11½c ₱ set; 14 oz., 40s., 10c.

Chemicals. — Cyanide of potassium, 98%–99%, jobbing, 23@24c ₱ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ₱ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ₱ lb.; Cal. s. soda, bbls., $1.20@1.40 ₱ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, French, 3½@3¾c; alum, $2.00@2.25; California refined, 1⅞@2c; sulphide of iron, 8c ₱ lb.; copper sulphate, 5¼@5½c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ₱ lb.; nitric acid, carboys, 8c ₱ lb.

Bone Ash.—Extra No. 1, 5@6c ₱ lb. No. 1, 4@5c.

Coal. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.00; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

Oils.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 47c; cs., 52c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

White Lead.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ₱ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

Red Lead.—500 lbs. and over at one purchase, ₱ lb., 6½c; less than 500 lbs., 7c.

Litharge.—Pure, in 25-lb. bags, 8@9c ₱ lb.

Borax.—Concentrated, 6@7c ₱ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

Manganese.—Pure, ₱ lb., 60c.

Sodium.—Metal, ₱ lb., $1.00.

Bismuth.—Subnitrate, ₱ lb., $2.00.

Mercury.—Bichloride, ₱ lb., 77c.

Molybdenum.—$2.00 ₱ lb.

Chromium.—90% and over, ₱ lb., $1.00.

Phosphorus.—American, ₱ lb., 75c.

Silver.—Chloride, ₱ oz., 90c@$1.00; nitrate, 55c.

Aluminum.—No. 1., 99%, small lots, 37c ₱ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

Uranium.—Oxide, ₱ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

New Patents.

Dewey, Strong & Co.'s Scientific Press Patent Agency, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING MARCH 8, 19 4.

754,112.—Oil Burner—G. W. Arper, Oakland, Cal.
754,276.—Syringe—E. Bartsch, S. F.
754,010.—Bread Cutter—O. Bernard, S. F.
754,043.—Bicycle—W. H. Bradley, Portland, Or.
754,051.—Air Rifle—T. W. Craven, Fairfield, Cal.
754,057.—Telephone—English & Ten Broeck, S. F.
754,297.—Meat Press—G. Freysleben, San Diego, Cal.
754,212.—Table and Bed—L. C. Graessle, San Jose, Cal.
754,312.—Saw Handle—P. M. Irish, Booneville, Cal.
753,980.—Pump—F. W. and C. A. Krogh, S. F.
754,325.—Wire Solder Rolling Machine—A. Lotz, S. F.
754,327.—Brake—J. B. Mabana, Tacoma, Wash.
753,992.—Facet Cutter—F. A. Marcher, Los Angeles, Cal.
753,993.—Dusting Frame—J. R. Mauran, Los Angeles, Cal.
754,334.—Conveyor — W. L McCabe, Seattle, Wash.
754,335.—Conveyor — W. L. McCabe, Seattle, Wash.
753,900.—Boiler—H. A. Miller, Selby, Cal.
754,337.—Blast Furnace—J. W. Pack, Berkeley, Cal.
754,007.—Necktie Holder—G. G. Parsons, Madera, Cal.
754,012.—Wrench—J. M. Reams, Seattle, Wash.
754,250.—Plate Lifter—G. S. Solomon, Bisbee, Ariz.
754,172.—Lawn Sprinkler—E. Sutherland, Los Angeles, Cal.
754,174.—Harrow Jack—N. W. Thompson, Erskineville, Or.
753,946.—Game—S. E. Wharton, Everett, Wash.
754,402.—Fault Locator—D. E. Wiseman, Spokane, Wash.
754,109.—Insulating Structure—O. F. Zahn, Los Angeles, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

Wire Solder Rolling Machine.—No. 754,325. March 8, 1904. A. Lotz, San Francisco, Cal., assigned to Pacific Metal Works of San Francisco, Cal., a corporation of California. This invention relates to improvements in machines for rolling and trimming wire solder. Crude solder as it comes from the molds in a long continuous strip has a rough unfinished surface; and it is necessary subsequently to run this strip through a sizing and trimming machine to give it a smooth uniform appearance. The object of the invention is to provide a machine simple in construction and operation capable of ready adjustment to roll solder in strips of any desired shape, and adapted to trim strip uniformly and deliver the strip ready for coiling separate from the trimmings.

Blast Furnace.—No. 754,337. March 8, 1904. J. W. Pack, Berkeley, Cal. This invention relates to improvements in furnaces, such as smelting or blast furnaces or the like. It consists in a novel construction of the furnace with exterior and interior water jackets, and said interior jacket is of such shape as to form an inner chamber through which communication may be had to make connection for burners where oil is to be used.

Syringe.—No. 754,276. March 8, 1904. Edwin Bartsch, San Francisco, Cal. The object of this invention is to provide a syringe of simple construction and of small cost as compared with those commonly in use, which will have a maximum capacity and be of a minimum size, which will not leak when filled, and which will be easy of manipulation and effective in operation.

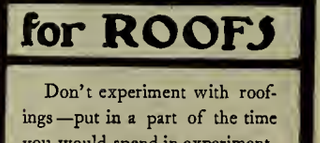
The Burt Exhaust Head.

No matter how large or how small your plant you do not want to have the roof or wall damaged by steam from the exhaust pipe. Order a BURT EXHAUST HEAD today; if not satisfactory, return.

"We are well pleased with the BURT EXHAUST HEAD." — Pittsburg Ice Co., Pittsburg, Pa.

THE BURT MFG. CO.,
Largest Mfrs. Oil Filters in the World,
221 Main St., Akron, Ohio, U. S. A.
Supplied also by Engine Builders, Dealers and Power Contractors.

Right thing



for ROOFS

Don't experiment with roofings—put in a part of the time you would spend in experimenting in investigating the merits of P. & B. Ready Roofing. Ask builders, ask contractors, ask men who have used it and who have made a complete study of roofs and roofings, and we are satisfied that you will cover your building with P. & B. Ready Roofing. If there was any other roofing that would answer the purposes so well, P. & B. Ready Roofing would never have its tremendous sale.

This roofing is used all over the world and every good building in every city is covered with it.

Interesting Mine Model.

Among the great drift mines of California, the Hidden Treasure-Mountain Gate, at Sunnysouth, on the Forest Hill Divide, in Placer county, is one of the most noted. The workings comprise upward of 10 miles of drift and stope, on a series of channels, the exact relations of all of which still remain partly in doubt, but in a general way are understood and are being operated in a systematic and scientific manner. The main working tunnel exteuds from Sunnysouth for 6 miles under the volcanic capping of andesite tuff and breecia. The gravel is breasted from the working faces and transported in trains of cars by electric locomotives to the surface, where the material is dumped into sluices and washed by water flowing from the mine workings, 300 cubic feet per minute being required. The dump has a daily capacity of 500 tons, though at present but 400 tons are being washed every twenty-four hours. The gravel is first dumped iuto the head box paved with wooden blocks. Below this is a 12-foot box paved with steel Hungarian riffles. In this short length of box 85% of all the gold obtained is caught, and this is cleaned up daily. This fact alone indicates the free-washing character of the gravel. Below the Hungarian riffles is 1700 feet of flume set on a grade of 14 inches to 12 feet. These boxes are cleaned up at long periods, two or three of the upper sections every two or three months. Little gold is obtained in the lower run of the flume, which is paved throughout with hard, siliceous cobbles taken from the mine workings.

Harold T. Power, general manager of these mines, has had made a model, on a scale of one-twelfth, showing the dumping bins, with automatic dumping arrangement, the apron for diverting the gravel to either of the two upper boxes at the head, and a limited section of the long flume, with an "undercurrent," where the boulders are cut and only the fine material passing the grizzly goes onto the table below. This handsome model of practical mining shows every detail of work in drift, dump house and flume. In the drifts not only the posts and caps of each set, but lagging and even the wedges, are shown. It has been presented by Mr. Power to the California State Mining Bureau, but before being placed on exhibition in the Mining Bureau in San Francisco, it will be taken to the Exposition at St. Louis, Mo. The accompanying engraving gives both a side and end view of the model, a study of which will make its operation clear to those who have no opportunity to see either the mine or the model.

Model of Gravel Washing Plant at Hidden Treasure Mine, Placer County, Cal.

Artificial Barriers in Torrential Streams.

The United States engineers of the California Debris Commission in charge of the construction of the debris dams on the Yuba river in California, have changed and enlarged their plans in the reconstruction of the barriers which were torn out by the flood of the early winter. Several plans have been submitted, but the conditions existing on the Yuba river are unusual and have made substantial dam construction expensive and thus far somewhat uncertain as to the ultimate result. The site of the dam on the Yuba river, although in the valley lands, is subjected to the wide variation of volume and current of water characteristic of mountain streams, and the difficulty of completing within the short space of the few months of the dry season when the river is comparatively low, has thus far rendered attempts at dam construction futile. It is now the intention to construct a series of dams, the first of which will be attempted above Marysville, where the stream is 1000 feet wide. In the former constructions sheet piling were employed. In the new dams ordinary round piles will be driven in four rows, being driven to a depth of 20 feet, forming a solid wall. On top of these will be placed massive concrete blocks, reinforced with sections of wire cables, to reduce the tendency of the blocks breaking up. This line of blocks has a width of 10 feet and a thickness of 18 inches, extending entirely along the crest of the dam from shore to shore. At either end of the dam is to be built a solid wall of masonry, composed of large blocks set in cement. Sheet piling will be driven both above and below the main dam to make it water tight and to reduce as far as possible the tendency to wash out—which is the greatest danger, particularly below the dam — in time of high water. In addition to these items of construction, a trench above and adjoining the pile bulkhead will be filled with heavy rocks, the upper tiers of which are to be cemented. The entire construction will approach solid masonry, reinforced with heavy piling in the interior section, and it is the opinion of engineers that these plans are likely to prove successful, as it is now known that a less substantial and costly structure cannot withstand the force of the great volume of water which comes down the Yuba in the winter season. It is stated that at the site of the proposed dam the river bed has raised during recent years not less than 13 feet, although comparatively little mining has been done in the territory tributary to the river. This is considered encouraging, and it is thought a dam built along the lines suggested will be able to withstand any freshet that may occur. Great dams have been constructed on other streams where there is great variation in the volume of water in the stream at various seasons, but these works have required years of toil and vast sums of money to render them enduring, and while it is possible to construct similar dams on the Yuba the expense is not justified.

AGAIN it has become necessary for the Governor of Colorado to call upon the State militia to preserve order in that State, this time in Las Animas county, of which Trinidad is the capital city. There are said to be 1500 unemployed men in that section armed and terrorizing the peaceable citizens of the State, and resisting the local authorities. These are the men who for several months past have been on strike, and now having failed to gain their demands have instituted a "reign of terror" in the coal regions of southern Colorado. No union or body of laboring men can ever hope to gain their desires by a show of lawlessness and the intimidatiou of those who do not agree with tbeir ideas or are not in sympathy with their methods. Not only does this sort of thing fail to accomplish the desired results, but it also loses the working men the respect and moral support of the public who otherwise feel an interest in their welfare.

ANOTHER attempt is being made to change the Federal mining law as applied to Alaska, a bill having been introduced in the Senate providing tbat withiu ninety days after the location, and before notice is filed, a shaft shall be sunk at least 10 feet deep, or au excavatiou made 10 feet long exposing the lode. At least twenty days' work is required annually on each claim, and a penalty is provided for making false affidavits of location or as to work performed. It does not seem expedient for the Government to make mining laws for one section differing from those of another section. The several States and Territories, and even mining districts, have the authority to add to the Federal laws, but can make no laws in conflict with the Federal laws. The Government establishes the minimum requiremeut and the State and Territorial Legislatures and miniug districts may make non-conflictiug amendmeuts thereto, increasing the amouut of annual assessment work, or requiring certain acts or work within a limited time after locatiou.

Location By Agent.

Much dissatisfaction is being expressed in some districts—notably those in some of the newly discovered gold fields of Alaska—over the location of a large number of claims by agent, in some instances the agent having power of attorney. One instance complained of is that in Ptarmigan Creek district, where it is said several prospectors, well equipped, went in in April, 1903, and spent the entire season prospecting. Late in the season a stranger came into the district aud staked claims to the number of 60 on that creek, taking others elsewhere. In all this industrious person, as agent, located claims for people in Dawson to the number, it is said, of 205. Whether or not the beneficiaries are Americans is not stated. Dawson, however, is in British territory and Ptarmigan creek is in American territory. In locating claims on the public domain the agent is acting within the provisions of the law. The object of the mining statutes is to advance the development of the undeveloped mineral resources of the public domain, and making certain provisions to this end, failing to comply with which the locator forfeits his claim to the ground located. It seems immaterial who takes up the locations, or how many claims are taken by one iudividual, as the law requires these claims to be developed to the extent of $100 worth of work or improvements annually. If the law is uot complied with the penalty is forfeiture and the location reverts to the public domain, and the ground may then be located by the first comer. In the instance above cited it is stated that the prospectors first on the ground lost all opportunity to secure claims for themselves, as the "agent" covered everything iu sight. If this be true, the prospectors acted in a most unusual way. Ordinarily prospectors in a new region promptly locate more ground than they can work, at the first sign of value discovered, either actual or prospective, and, being first on the ground, have the best chance. Later they keep what appears the most desirable, and have claims either to sell or give away to those who come later. That the mining law requires any change iu respect to location by agent is not apparent, but a strict enforcement of existing laws would inure to the benefit of the Government and be of great service iu the development of the mineral industry. The real trouble arises when peaceable men undertake to claim locations upon which tbe assessment work required by law has not been performed. The former locator, although having failed to comply with the law, often by threat and intimidation witb a display of force keeps men who are peaceably inclined from acting within their rights as provided by the mining law. Every new mining camp has the remedy for this sort of thing at hand. Organization of the law-abiding element will always accomplish tbe desired end and gain the "greatest good for the greatest number."

Uniform Code of Bell Signals.

State Commissioner of Mines E. L. White of Colorado has issued a State mine-bell code, under the authority vested in him by the law. The code is essentially the same in all important respects to that which has been in use in California for several years, and which these several years of trial have demonstrated to be a satisfactory code of signals. This newly adopted code has remedied a great defect in the codes in use in some parts of Colorado, where the code suggested by the Western Federation of Miners has beeu largely adopted—that of indicating wheu men were to be hoisted, for which there was uo premonitory signal. In some instances three bells were given to indicate that men were on the cage or skip, but no further bell to denote that they were ready to be hoisted. After three bells, the engineer would begin to hoist. The better signal in the new code is "three-one." The person desiring to go from one level to another can now first ring the level to which he wishes to go, followed by three bells; then, taking his place on the skip, give the final signal to be hoisted or lowered, as the case may be. There has been no uniform, legalized bell-signal code in use iu Colorado heretofore, and Commissioner White has performed a praiseworthy act in taking steps to put one in force that will not only bave the merit of uniformity in Colorado, but which will also agree with that in some other States. If the mine inspectors or other authorities in other States would do likewise, within a short time the code of bell signals would be uniform throughout tbe Western United States.

A New Steel Enterprise.

It is announced in a local paper at San Diego, Cal., that a corporation has been organized in that city for the purposes of mining, manufacturing, etc., the principal feature of which will be the making of iron and steel from the ore of the Tepustette mines in Lower California. The ore is there in large amount, and capable judges have pronounced this ore to be a superior quality of hematite and magnetite. In 1891 a somewhat similar proposition was launched in San Diego—a company to make iron direct from ore by the J. C. Eames process, and the work went so far as tbe completion of one reverberatory furnace and the partial construction of two others at Roseville on San Diego bay, but the project was abandoned, it was stated, because of insufficient financial aid. The intention was to employ crude petroleum as fuel. The ore was to have been crushed in breakers and rolls and ground fine in Chile mills, mixed with coke dust that had previously been treated with clay water, and after drying spread on the hearth of the reverberatory. The application of the petroleum—steam blast, it was believed—would supply the necessary heat, and the result would be the making of a high-grade carbon iron direct from the ore without the intervention of the blast furnace. The idea was based on the practice of the Carbon Iron Company of Bethlehem, Pa., where the process had been successfully applied, employing natural gas for fuel. The Carbon Iron Cumpany produced a fine grade of iron which found a ready sale. As the use of natural gas for fuel is not wholly unlike the result of the petroleum steam blast, the proposition seems feasible, and if sufficient capital is provided for the experiment at San Diego success may result. In the Carbon Iron Company's furnaces the ore became a bright red soon after the flame was turned into the furnace. The soft, agglutinated, semi-molten surface of the fused iron ore was rolled up by workmen with their rabbles, like snowballs. These were withdrawn from the furnace and squeezed into blooms, and in this form were sold to tbe trade.

THE lead miners of the Kootenay district of British Columbia have appealed to the government to extend the "lead bounty act" to a limited quantity of ore to be exported and smelted abroad—provided the extension shall not prejudice the payment of the bounty on ores smelted in Canada; and provided that the maximum freight and treatment rate shall not exceed $10 per ton, and the marketing charge shall not exceed $20 per 2000 pounds, and the limit on zinc shall not decrease from 10%, and the penalty on excess sball not exceed 50 cents per unit. A great portion of the lead-silver ore in the region about Nelson is low grade, as far as known, and this ore cannot be mined and smelted at profit unless a subsidy be granted in some form. Either they must receive a bounty or have a very low transportation and treatment charge. The smelters demand 40,000 tons annually of ore which will run 45% lead, or the charge will be $17 per ton for treatment. It is doubtful, from the statements made by the local press, whether the mines of East Kootenay can supply this requirement.

NO business is more legitimate than honestly conducted mining. Money invested in mining enterprises results in a distribution of the money to a score of other industries dependent upou the mine. The iron miner and smelter, and the manufacturer of every class of mining, milling and reduction machinery, is directly benefited. The farmer, the merchant and others engaged in a great variety of enterprises have the money expended in mine equipment, development and operation, and this whether the mine venture be profitable or not. Should the mine prove to be a producer of gold, silver, copper or any other metal or valuable mineral, its output goes to swell the grand total of its particular product in use in the world. Should the venture prove profitable, then the benefits flowing from the operation are of even greater importance.

CONCENTRATES.

THE white mineral specimen from Columbia river, Oregon, is rhyolite tuff (volcanic ash), and may possibly be made useful as a polishing agent.

✤✤✤✤

THE placer miner usually considers 20 miner's inches of water—30 cubic feet per minute—a sluice head in a 12-inch box having a grade of 8 inches in 12 feet.

✤✤✤✤

THE term "sand carbonates" originated in Leadville, Colo., and refers to a disintegrated granular carbonate of lead and has no reference to copper ore of any description.

✤✤✤✤

MINERAL paint is made of either hematite ores, or from roasted iron sulphides. In some variety of natural iron oxide the color is brighter than in others, but none of them make a brilliant red. Cinnabar makes a bright vermilion red, but is much more expensive than iron oxide paints.

✤✤✤✤

THE mineral specimen from Placerville, Cal., is roscoelite, a variety of vanadium mica. This mineral was at one time supposed to be invariably gold-bearing, but the occurrence of gold with this mica is probably merely accidental, as gold sometimes occurs in garnet, in hornblende and in other minerals.

✤✤✤✤

CARBORUNDUM, the strange mineral made in the electric furnaces at Niagara Falls, New York, is extremely hard—nearly as hard as diamond—but is too fragile for use as a substitute for carbonado (the black diamond) in diamond drills. As an abrasive, carborundum is superior, but it has not as yet been applied to rock boring.

✤✤✤✤

SOME of the mining districts of Colorado are at a high altitude. Alma, in Park county, is at an altitude of 10,240 feet; Breckenridge, in Summit county, at 9524 feet; Caribou at 9905 feet, Creede at 9000, Cripple Creek at 9396; Georgetown, 8587; Kokomo. 10,654; Leadville, Lake county, 10,185; and Sunshine, Boulder county, at 12,945 feet above the sea.

✤✤✤✤

IN a cyanide plant for Colorado it was proposed to dispense with the montejus as a means for filling and operating filter presses by pumping the slimes to a tank situated on the hill back of and 180 feet higher than the mill, thus securing about 80 pounds direct pressure. The object of the tank was to secure a direct and nearly uniform pressure in the operation of the presses.

✤✤✤✤

A CUBIC FOOT of solid quartz rock weighs about 165 pounds. A cubic foot of dry tailings from this quartz will weigh about 100 pounds. The usual estimate of quartz ore in place is 13 cubic feet equals one ton. Where only 10 cubic feet are required to make a ton, the ore must be heavy in sulphides or their oxidized products, such as lead or copper carbonate, etc.

✤✤✤✤

THE rock specimens from Midas, Nye county, Nev., are quartz, with mica. That looking like gold is stained with iron oxide, the bright golden scales are mica. That resembling arsenical pyrite is also mica, similar to that above mentioned, but unstained by iron. The reddish-brown piece is quartz stained by iron oxide. If gold be present in these rocks it should be readily detected by panning.

✤✤✤✤

THE best screen for treating fine gold in ores is that screen which will retain the ore in the battery or other crushing device until the material is sufficiently fine to free the gold from the gangue. The subsequent recovery of the gold is another problem which may prove to be either easy or difficult of accomplishment. Granular ores pass most readily through wire cloth screens. Flaky, flint-like ore passes more readily through slotted screens.

✤✤✤✤

SEA WATER holds in solution the salts of various metals which are derived from the dissolution of rocks on the land. A gallon of sea water contains about 2500 grains of saline matter, of which 1890 grains consist of sodium chloride (common salt). In 1000 parts of sea water there are about 29 parts of sodium chloride, 0.5 part potassium chloride, 2 of magnesium chloride, 2.5 of magnesium sulphate (epsom salt), 1.5 of calcium sulphate (gypsum), and it is said also to contain gold. The amount is variously stated at from 2 to 3 grains per ton of water, or 8 to 12 cents per ton.

✤✤✤✤

THE construction of buildings in regions of heavy snowfall should be designed with the fact in view that for each square foot of horizontal surface freshly fallen snow varies from five to twelve pounds. In some mountain regions, buildings erected in summer have been crushed by the snows of the following winter, an insufficient factor having been allowed for the great weight of snow. It is no uncommon thing in regions of heavy snowfall to find the eaves of mills and other mine buildings broken off by the weight of the saturated snow lying on the lower portions of the roofs.

✤✤✤✤

THE attempt to effect perfect concentration from stamp batteries without hydraulic concentration can only be partially successful, for the reason that it is a physical impossibility to separate particles of the same specific gravity and greatly varying size from a gangue mineral of uniform specific gravity, though varying much from that of the mineral which it is desired to concentrate, with the same grade or vibration of table, belt, or other mechanism, and with a stated quantity of water. There are many mills where this is to-day the practice, and where it has been the practice for years, and the managers are satisfied; but if sizing were resorted to, a higher saving would undoubtedly result with no consequent increase in expense.

✤✤✤✤

MISPICKEL containing gold can be successfully treated by a combination of metallurgical processes. The ore is first crushed and then roasted in a reverberatory furnace to free it from arsenic, the fumes from which are collected in a chamber and condensed in the form of white arsenic (arsenious acid). The roasted ore is then treated by the bromo-cyanide process to extract the gold. Arsenical ores should be roasted with carbon in some form—preferably pulverized coke. This reduces the arsenic to metallic state which, as fast as formed, volatilizes and passes off to the condenser in the form of fumes. If the carbon be not added, only a portion of the arsenic will pass off, leaving the ore in but little improved condition for subsequent treatment.

✤✤✤✤

CHANNELS composed of andesitic boulders, cobbles and gravel are sometimes gold-bearing, but when such is the case it will probably be found that the channel also contains quartz and other hard crystalline rocks, which are gold bearing. Although andesite in many regions encloses gold-bearing veins, there are no rocks of this kind containing gold veins on the west side of the crest of the Sierra Nevada mountains, in California, as far as known, and all of the ancient channels thus far discovered to be auriferous have cut through older crystalline rocks. In a few instances later channels containing chiefly volcanic rocks, have cut through older gold-bearing channels which have derived their gold from the older rocks, and below such points of intersection the lava channels are also gold-bearing.

✤✤✤✤

IN extracting gold and silver from copper matte, one process is that of roasting the matte to convert the silver to sulphate, in which condition it is leached out by means of water, the silver being precipitated on metallic copper, the gold still remaining in the matte. Another method is to concentrate the matte by further fusion in a reverberatory to black copper, granulate it, grind, roast, and leach with salt solution by the Augustin process and precipitating silver in the usual manner. The residue containing the copper and the gold is then concentrated in a reverberatory furnace until a small amount of copper is extracted as a copper bottom, carrying nearly all the gold. The method of treating these enriched "copper bottoms" as practiced at Argo, Colo., has never been made public.

✤✤✤✤

NO ORE, even if it show no metal—gold, silver, copper, lead or other material of undoubted value—should be discarded and thrown over the dump merely because its appearance is unpromising. Ores of high specific gravity are not always valuable, nor are light porous ores always worthless. In the Lava Beds district of San Bernardino county, Cal., is an ore so porous and light from oxidation of the original sulphides as to resemble pumice, yet this ore contains forty to sixty ounces silver per ton in the form of dust-like chloride. Some of the iron ore of the croppings of the Congress mine in Arizona was so porous that a man could easily lift a block of it as large as a barrel. Some ores of great weight due to the presence of a large amount of heavy spar (baryta) are commercially worthless, such as some of the silver ores of Calico district, Cal. Many iron ores are practically without value, owing to limited occurrence in the vein or deposit, or to situation. Most ores and metals of high specific gravity (8 to 10 or over) are valuable. Among these are copper, 8.8; the tellurides of gold and silver, 8 to 10; platinum, 14; platin-iridium, 19; and gold, 15.6 to 19.30.

✤✤✤✤

BY MATTE or matting is meant the process of running the metal out of the rock—not in pure state, but combined with sulphur and other minerals, and in a concentrated condition. Thus a low-grade copper-iron sulphide ore on first treatment can be made to yield a matte consisting of 40% copper, the remainder being principally sulphur and iron. Copper matte generally also contains gold and silver, dependent upon the ore from which the matte is derived. Copper is not an essential constituent of "matte," though sulphur is—for there are also iron matte, zinc matte, etc., with no trace of copper. "Speiss" is not "matte," but is a compound of arsenic or antimony, with iron, cobalt, nickel, lead, bismuth, copper, etc. It has a metallic luster, and is nearly always crystallized, is of high specific gravity, and when it is the product of treating base antimonial, arsenical or cobaltiferous silver or gold ores, is high in the precious metals, though having a greater affinity for gold than for silver. Speiss, at one time the bane of the smelter, is now sometimes intentionally created to collect precious metal values, and also of copper from ores treated in a reverberatory matting furnace.

✤✤✤✤

A PLACER LOCATION or placer patent cannot confer any extralateral right, as to any lode or vein, the apex of which lies within the lines of the placer claim. In order to secure such right to follow the downward course of the vein beyond the lines of the placer location it is necessary to locate the vein separately, the same as on the unoccupied public lands. In such case the extralateral right is defined by the lode claim boundaries, whether these coincide with the placer location boundaries or not. Should the discovery of a vein or lode not be made within the placer until after patent has issued, the placer claimant can hold only such portion of the vein as lies within the lines of the placer extended downward vertically. In the case of Aurora Lode vs. Bulger Hill Placer (23 L. D. 95) the court said: "The discovery and location of a placer mining claim establishes in the owner the right to the possession of the superficial area within its boundaries for all purposes connected with and incident to the use and operation of the same as a placer mining claim. Such location, however, does not operate to give title or right of possession to veins, or lodes, within its limits, or preclude the right of discovery and location thereof by others."

✤✤✤✤

THE carnotite deposits of Montrose county, Colorado, occur in two districts near the Utah State line. One series of deposits is along a sandstone bluff 700 feet above the creek. The carnotite, a canary yellow mineral, is found in bunches in white sandstone, or along the contact of the sandstone with underlying shale. These deposits occur within a few feet of the surface. The ore bodies are generally flat-lying streaks and sheets a few inches thick, which pass both above and below into the common white sandstone, and which also gradually disappear when followed into the hillside. It is said that the deposits show every evidence of being of very recent formation. On Roc creek carnotite occurs in the plane of a fault fissure intersecting horizontally bedded sandstone. The displacement has been about 50 feet, the fissure dipping north at 70°. In this fissure the carnotite occurs as small irregular branches in a loose mass of crushed sandstone, and also as an impregnation in the solid portion of the sandstone strata. Copper carbonates also occur in the same rock strata at a distance of a few hundred feet from the carnotite. The mineral occurs in a number of places in western Colorado and eastern Utah, but as far as known not any place in large quantity.

✤✤✤✤

MILL SCREENS are manufactured by many different firms and there is a lack of uniformity in them. Generally speaking a No. 5 screen is equivalent to 20 meshes to the inch; No. 6, to 25 meshes; No. 7, to 30 meshes; No. 8, 35 meshes; No. 9, 40 meshes; No. 11, 55 meshes, and No. 12, 60 meshes. In South Africa on the Rand it has become the custom to designate a screen by the square of the number of meshes per lineal inch, thus a 20-mesh screen is called a 400, a 30-mesh is a 900, etc. If this idea were generally adopted it would result in greater uniformity and the character of the screen referred to would be much more readily understood, and if in addition to the number of apertures per square inch the number of wire of which the screen were made be given, or if a punched or slotted screen, then the size of the aperture as indicated by wire gauge, this would be still more valuable, in making clear the character of screen employed in any particular mill work. A screen may contain 400 meshes per square inch, but be constructed of wire so heavy or so fine as to reduce the superficial area of the apertures, or increase it to such an extent as to make comparison with other screens of the same number of mesh worthless. Some ores require a heavier screen than others to be durable. It is always desirable to have a screen as thin as possible and at the same time secure a substantial and enduring screen. A given screen which in one mill will last two weeks, in another may last a month. The higher the discharge the longer is the screen likely to last. A low discharge and heavy feeding will quickly wear out a screen, though in the latter case the loss is chiefly due to breakage.

✤✤✤✤

MILL PLATES which have been treated with nitric acid until "eaten through" are in undesirable condition, but thorough dressing and rubbing with quicksilver should put them in fair condition again, unless they have become hardened by excessive use of cyanide of potassium, when they should be annealed. If badly corroded, they should be replaced by new plates. If the plates discolor, it is probably due to the character of the ore or the battery water used, or both. When the bronze-colored film forms on plates no amalgam is caught or formed on such discolored surfaces. Sodium amalgam is a valuable aid in getting plates in condition. Keep adding it occasionally and dress frequently—that is, brighten the plate by frequently hanging up and rubbing with a brush, but do not remove the amalgam already formed. No surface is equal to a layer of gold amalgam to catch more gold. Allow it to remain and endeavor to gradually reduce the discolored area. It will require time and patience, hard work and the loss of some gold to arrive at this desirable condition, but it pays to do it. Do not use nitric acid on the plates. It unites with the "quick" forming nitrate of mercury, which has a tendency to disintegrate the copper. In some instances the introduction to the ore feeder, or the bin of a small quantity of quicklime which will be crushed with the ore, is found beneficial—this when the ore or battery water contains ferrous sulphates or free sulphuric acid, which the lime has a tendency to neutralize, and thus protect the plates from attack of the acid. The above are the remedies usually employed with greater or less success in treating discolored amalgam plates.

Wet Concentration of Ores by the Sherman System.

Written for the MINING AND SCIENTIFIC PRESS by
FREDERICK WOOSTER SHERMAN.

To any one who has given much thought to the wet concentration of ores, it has surely become apparent that the chief loss is always through the medium of the fine or slime particles of mineral. The loss from this source is much higher than is geuerally supposed, as it will average from 20% to 40% of the entire value of the ore. Nor does the writer think it possible to raise the saving much above 75% without some system of classifying the fine ore and freeing the same from an excessive amount of water before it is delivered to the concentrating tables for treatment.

Different schemes have been resorted to at various places to correct the loss of the finer particles of mineral that were being carried away in the water. At the Anaconda Works in Montana this class of material was conveyed to large tanks or reservoirs, where the same was simply allowed to settle, and then worked through the smelter to the best advantage possible. At the Silver King mine, Park City, Utah, the slimes are forced through filter presses, then shipped to the smelter, and thus the values are recovered; again, in California you will find below the conceutrating tables long canvas plants that to some extent correct this loss.

There are many concentrating propositions over the country where none of the above-mentioned methods would successfully apply—properties that are not near enough to a smelter to permit of settling and then smelting this fine product; properties that do not have an ore of sufficient value to permit of filter-pressing the slimes and then shipping to a smelter; properties where canvas plant concentrates would be of too low grade to be of any great value. It is hoped that the following article, giving a description of the above-mentioned system and the results that can be obtained by same, will prove of interest to all parties, and especially so to parties operating concentrating plants over the mining world that have not in some satisfactory manner been able to correct the above-mentioned losses.

The first system of these classifying tanks was installed at the Daly-West concentrating plant one year ago last August; a second system at the Daly-Judge plant early last spring; a third system is now being installed at the new Honerine concentrator at Stockton, Utah, and a fourth system in a tailings plant that is now being erected to rework the tailings from the present concentrating plant of the Daly-West.

Without some explanation it might be remarked that the fact of the Daly-West building a plant to rework the tailings from the present mill does not speak very well for the system there iu use. As an explanatiou, some figures from the past year's report will be submitted to show what the present system did accomplish and what is planned to be accomplished by the new plant.

The average grade of the ore milled at the Daly-West during the year ending Dec. 31, 1903, was 6.97% Pb. (galena) and 16.22 ounces Ag. The average tailings were 0.319 of 1% Pb. and 4.046 ounces Ag. Thus the mill made a saving of 95.42% Pb. and 75.10% Ag.

The new tailings plant is being erected with the idea of bringing the silver saving up to a point where the recovery will be from 85% to 90%. It is expected that the new mill will rework the tailings at a cost of from 10 to 15 cents and will be successful in making a net profit of from 30 to 50 cents a ton. Nearly the entire concentrate product will be derived from the recovery of the silver in combination with iron sulphides. This plant will be in commission soon after the middle of March, aud it is confideutly expected that its actual work will verify the above figures.

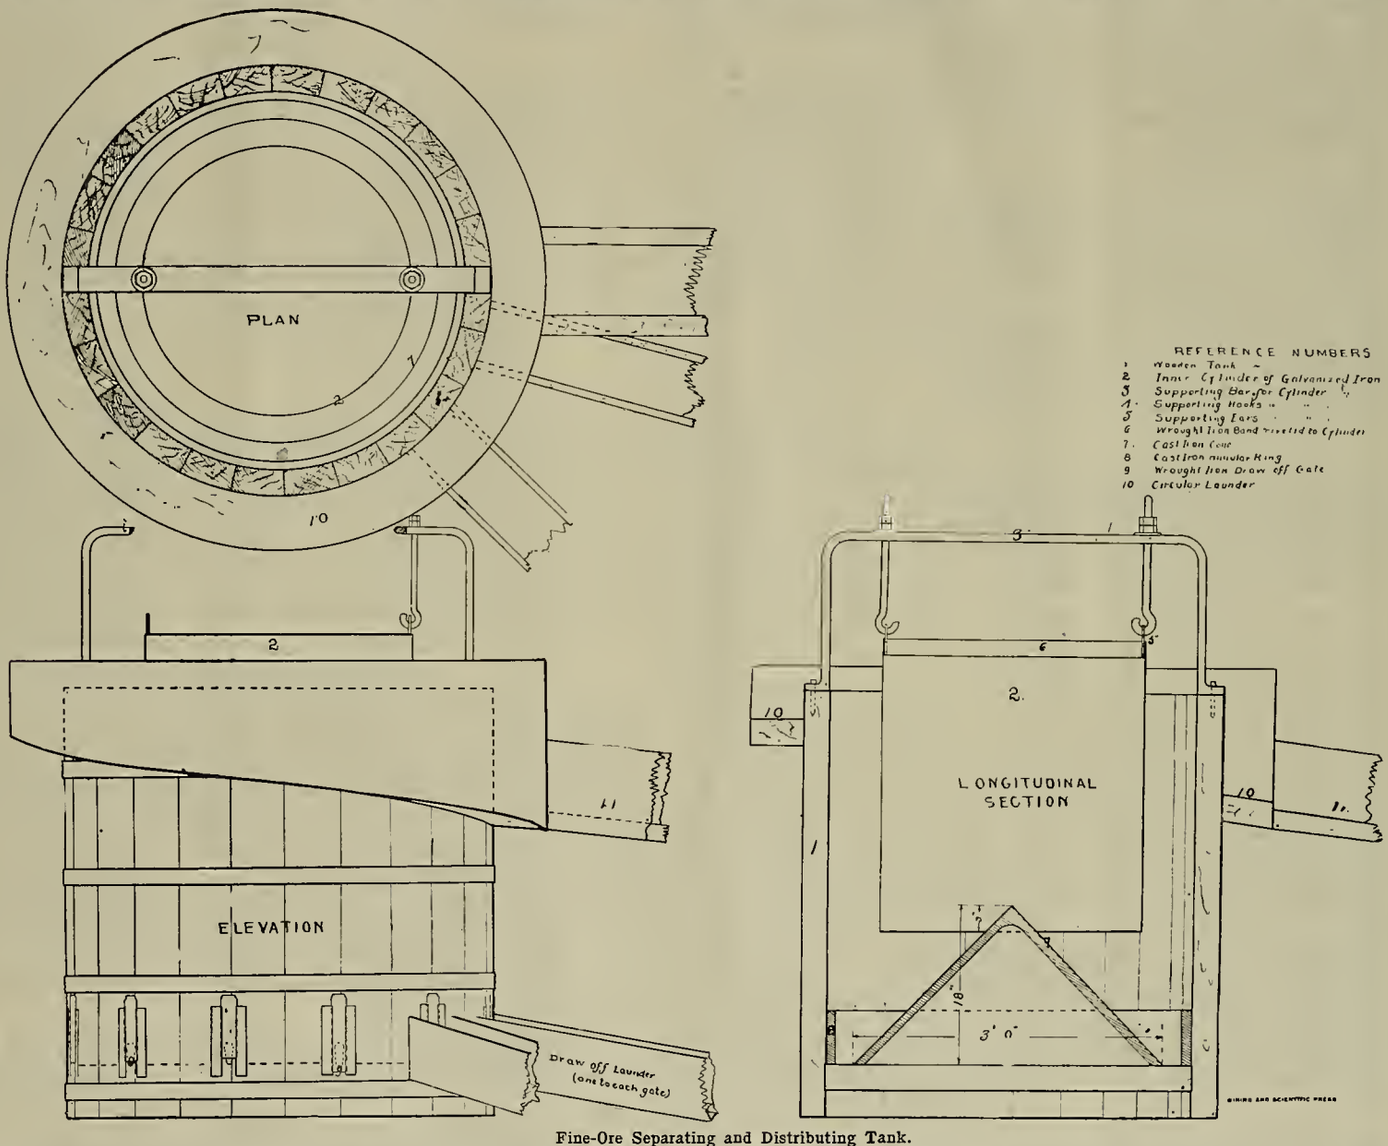
In order that the followiug explauation of the system may be more readily uuderstood, drawings have been prepared of the fine ore separating and distributing tank and the system of fine ore settling and classifying tauks. In each instance there is shown a "top plan," a "side view" and a "longitudinal sectiou," with the different parts designated by numbers, to which reference will often be made.

The first application of the system, as applied to the regular jig concentrator, is the installing of one of the fine ore separating and distributiug tanks just below the last revolving trommel or jig sizing screen. This tank is 4 feet in diameter and 4 feet deep and has suspended within it a galvauized iron cylinder which takes up just one-half the surface area of the tank. It is elevated 6 inches higher than the top of the tank and extends downward to within 15 inches of the tank's bottom. This cylinder is designated (2) in the drawing. Resting on the bottom of the tank and extending to a point 3 inches above the bottom of the cylinder is a cast iron coue. This is shown in the "longitudinal sectiou" and designated (7). Encircling the top of the tank and attached to it is a launder (10). The outside of this launder is made of galvanized iron and extends 3 inches higher than the staves of the tank, while the bottom of the launder at its highest point is 3 inches lower than the top of the tank; thence the bottom has a fall each way around the tank of 6 inches until it comes to and joins a delivery spout or launder.

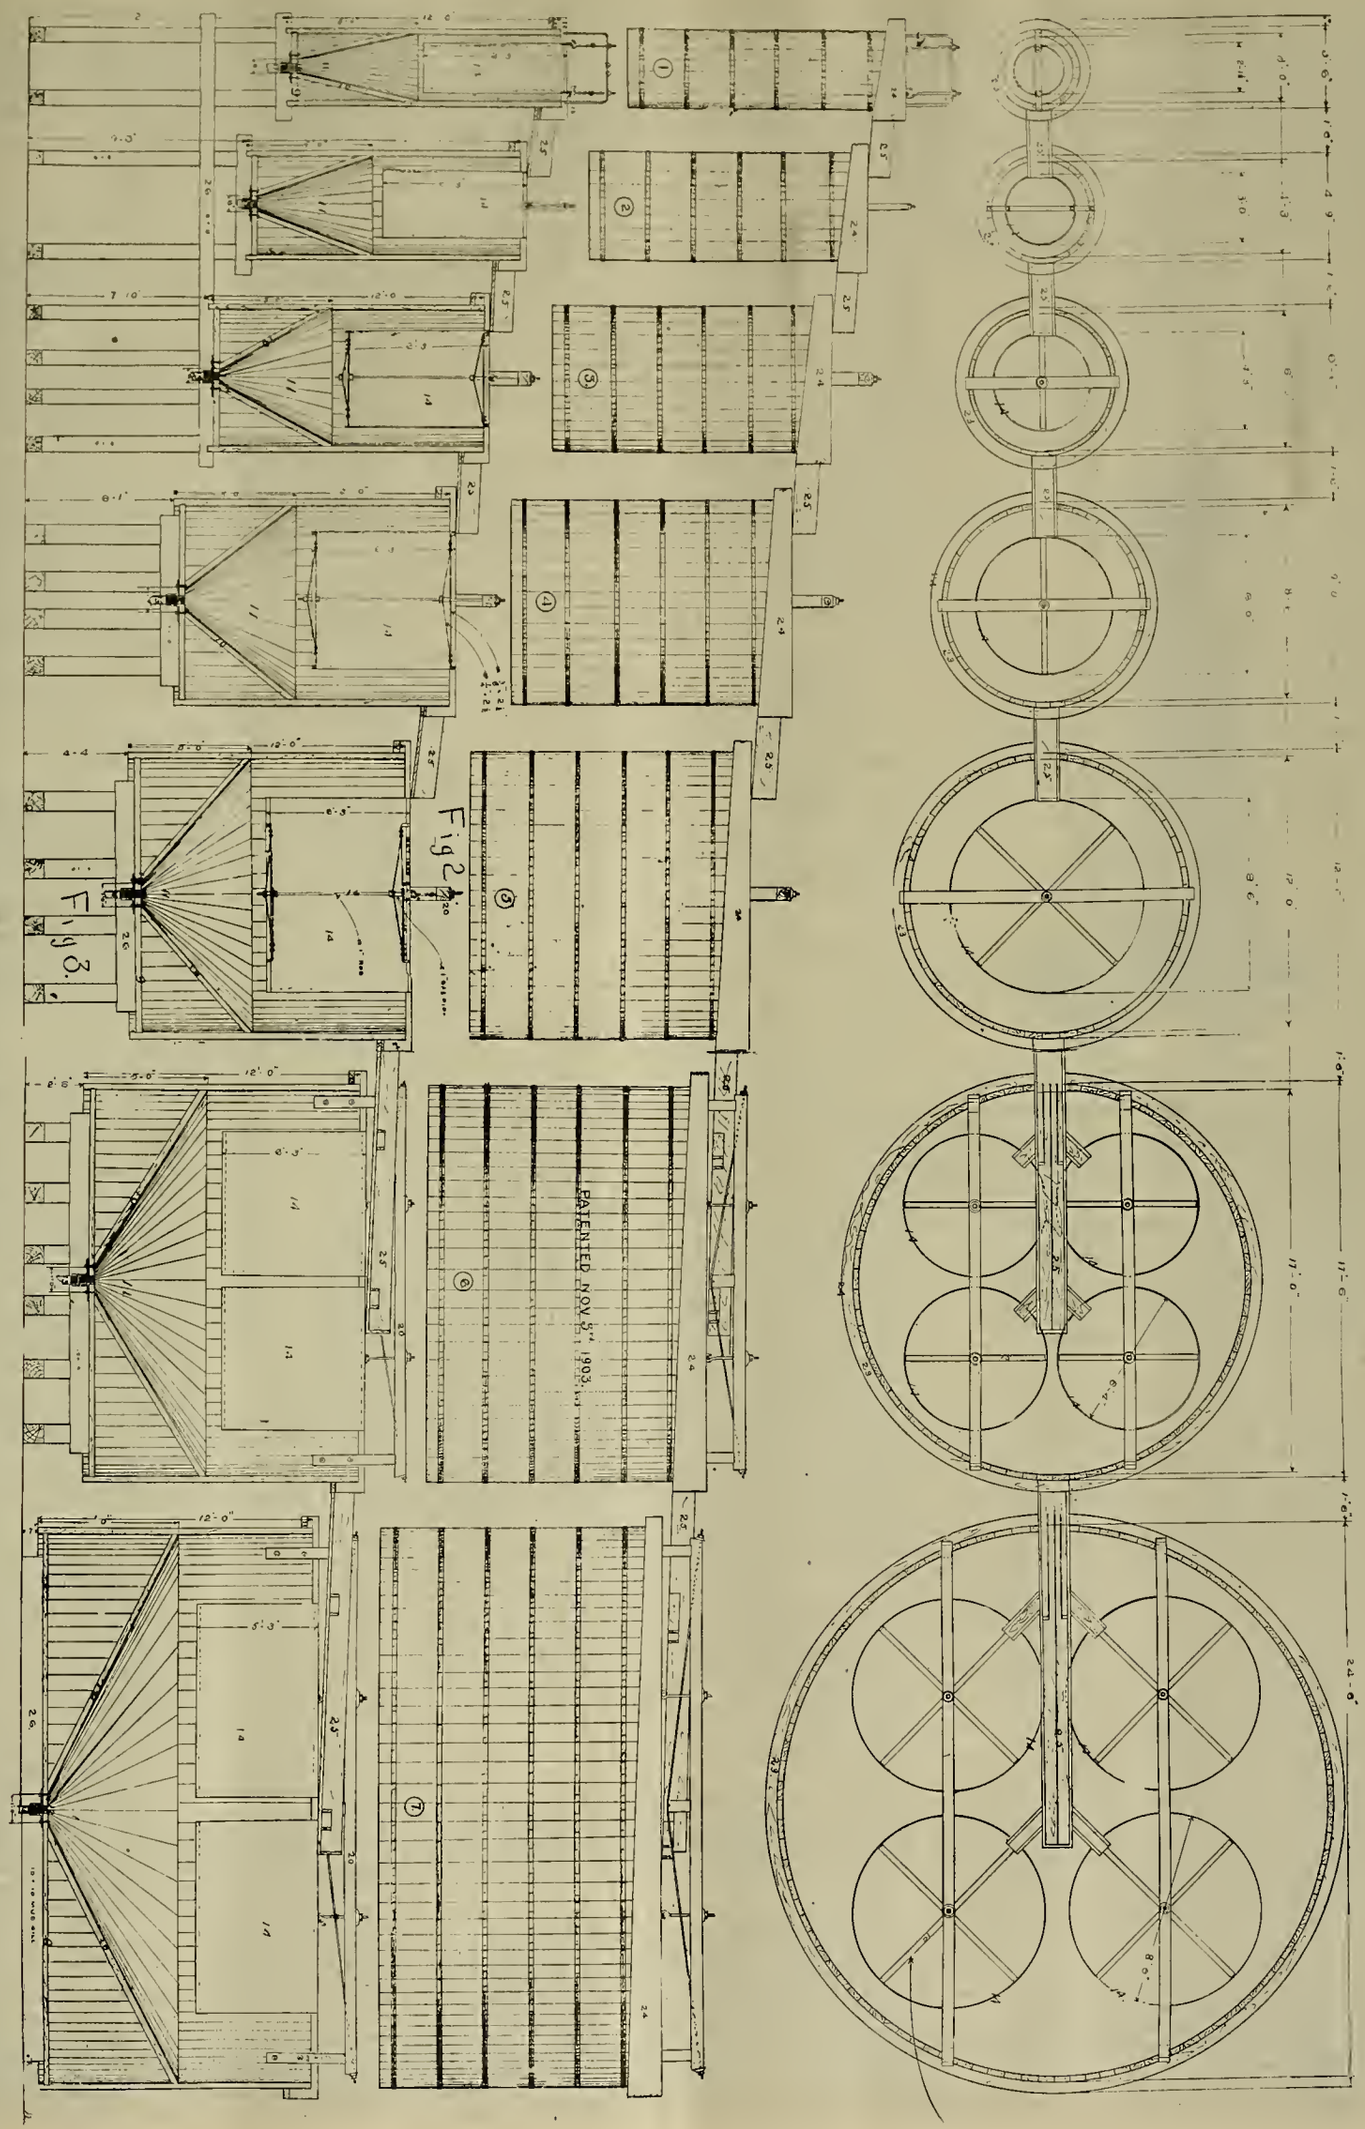
This tank is for the purpose of separating the fine ore and slimes from the coarser products, the latter going to the fine jigs for treatment and the fine ore and slimes being conveyed by launder to the system of settling and classifying tanks.

This tank receives the undersized product from the last revolving trommel. The product, accompanied by the water that has carried it through the system of revolving screens, drops into the cylinder (2); thence it passes downward to a point in the tank just below the bottom of the cylinder, where a separation takes place; the coarser particles, dropping onto the cone, are conveyed to the sides of the tank, thence through openings (9) to outer launders, which in turn convey them to the jigs for treatment. The finer particles of ore, still remaining in suspension in the water, are carried up in the circular space between the outside of the cylinder and the inside of the tank, overflow the top of the tank, drop into the launder (10), thence into the delivery spout (11), whence they are conveyed to the system of settling and classifying tanks. Only two of the openings (9)—the two directly opposite each other—are used in letting out this coarser material. The size of these openings is regulated by adjustable gates, so only a limited amount of water passes out with the jig product.

The next application of the system comes with the installation of a second oue of the fine ore separating and distributing tanks at a point far enough below the mills used to regrind the middlings from the jigs, to permit of the reground product being carried through a launder by gravity and dropped into the cylinder of the tank. It is also placed high enough above the concentrating tables so that the coarser product from this tank can be conveyed by launders



Fine-Ore Separating and Distributing Tank.



Sherman Fine-Ore Settling and Classifying Tanks.

to the tables for treatment. This tank not only receives the reground material from the mills, but also receives the tailings from the last fine jigs, as these tailings carry certain slime values which make a further treatment necessary.

This tank performs virtually the same kind of work as the first one, the fine ore and slime being separated from the coarser ore, the latter product being distributed to as many concentrating tables as are required for the successful working of the same. Each table receives its feed from one of the openings (9), though six tables have been found ample to handle this coarse feed from one unit of a concentrator treating 400 tons per twenty-four hours. The fine ore and slimes are carried by launder, or, when necessary, by the assistance of a centrifugal pump, to the system of fine ore settling and classifying tanks.

At this point in the operation all the fine ore and slimes have been diverted to the system of tanks, with the exception of a small amount which passes out through the gates (9) with the coarser material to the concentrating tables. In order to catch this fine ore and slimes, the concentrating tables (Wilfley pattern) are set with a raise of 1 inch toward the discharge end. As soon as this product falls on the table, the water carrying the slimes and fine ore leaves the coarser feed, passes over the riffles directly across the table, is caught up and by means of a centrifugal pump joins the other fine ore and slimes going to the system of tanks.

Before entering upon a description of the tank system, it would no doubt be well to give a description of the treatment of the coarser table ore. From the six Wilfley tables treating the coarser material there is made a finished concentrate, a middling, a tailings rejection, and a fine ore and slime product —mention of this last class having already been made. It is especially of the treatment of the middlings that further mention should be made. These middlings are carried by their respective launders to a common centrifugal pump and thence elevated to a third fine ore separating and distributing tank, which distributes the same to a second series of four Wilfley tables for further treatment. The water at this point carries little or no slime values and is allowed to go direct to the tail race. These tables make a finished concentrate, a middling and a tailing rejection. The middling product is again returned to the same four Wilfley tables in like manner as are the middlings from the first series. With a large middling coming in between the finished concentrate and the tailing rejection, it is found comparatively easy to make a high-grade concentrate and a poor tailings rejection.

THE SYSTEM OF FINE ORE SETTLING AND CLASSIFYING TANKS AND THEIR METHOD OF OPERATION.—This system of tanks takes the material which is fine enough to remain in suspension under a strong current of water and makes seven or more distinct classifications of the same; it frees each class from an excessive amount of water and delivers it to its respective concentrating table with only that amount of water necessary to give the pulp the right consistency for the successful working of the same. A system of seven tanks seems to be about the right number for the successful treatment of ordinary concentrating ores, though instances have been found where a system of eight tanks was needed. The accompanying drawing shows a system of seven tanks.

All the tanks in this system are 12 feet deep; the first or smallest tank in the series is 3 feet in diameter, and each succeeding tank doubles the preceding one in gallon capacity until the last tank is reached, which is 24 feet in diameter. Suspended in each of the first five tanks is a galvanized iron cylinder 6 feet 3 inches deep, each cylinder having a diameter sufficient to fill one-half the surface area of its respective tank. Each cylinder is suspended in the center of and 3 inches higher than its tank and extends downward into the tank 6 feet. In the last two tanks there are four cylinders in place of one, though the combined surface area of the four is one-half the surface area of the tank. The only reason for having four cylinders in place of one is the difference in favor of the cost of construction. In each tank there is an inverted cone-shaped false bottom, with its lowest point encircling the pipe outlet (13), thence raising up 5 feet and resting against the staves of the tank. (This forms the settling pocket (11), which is a receptacle virtually freed from all current.)

At the top of each tank there is a circular launder (23), shown in the top plan. The outside of the tank forms the inside of the launder, and a sheet of galvanized iron (24), shown in plan, makes the outside of the same. The bottom of the launder is formed by bolting segments of wood to the staves of the tank. At its highest point the bottom of the launder is 3 inches lower than the top of the tank, thence it has a fall each way of 9 inches until it terminates in a common delivery spout (25). The tanks are so arranged as to elevation that delivery spout of one tank is high enough to deliver its flow of material into the cylinder (14) of the succeeding tank, the last tank in the series being 10 feet 7 inches lower than the first.

With the above description, it is hoped that the following explanation of the working of the tanks will be readily understood.

As heretofore stated, the tanks deal only with that material which is fine enough to remain in suspension under a strong current of water. The current bearing this material drops into the cylinder of the first tank. The fact that the cylinder is 3 inches higher than the top of its tank causes the product to pass downwardly through the cylinder; then it raises up in the circular space between the outside of the cylinder and the inside of the tank, overflows the top of the tank into the circular launder and passes through the delivery spout (25) into the cylinder of the next succeeding tank. As the tanks double in gallon capacity and the same amount of water passes through all the tanks—the amount of water going out with the table feed of each tank really making no perceptible difference—the velocity of the up-cast current is reduced one-half each time, and each time this up-cast current finds a series of particles too heavy for it to raise; hence these particles settle into the receptacle (11) and pass through the pipe outlet (13) to their respective concentrating tables for working. The outlet is so valved that the classified material may be delivered to the table with only the right amount of water for the successful working of the same.

Thus it is quite obvious, as the operation progresses from the smaller to the larger tanks, that the current must become slower, that its lifting power is reduced one-half in each succeeding tank, and that a thorough classification must result and a separately classified product be secured from each tank in the series.

The following is a screen test showing a classification made by a series of six tanks at the Daly-West:

PRODUCT FROM NO. 1 TANK.

Stopped on a 30-mesh screen	4%
" " 60 mesh "	14%
" " 100-mesh "	54%
" " 150-mesh "	20%
" " 200-mesh "	4%
Passed a 200-mesh "	4%

PRODUCT FROM NO. 2 TANK.

Stopped on a 60-mesh screen	1.25%
" " 100-mesh "	40.25%
" " 150-mesh "	42.00%
" " 200-mesh "	12.50%
Passed a 200-mesh "	4.00%

PRODUCT FROM NO. 3 TANK.

Stopped on a 100-mesh screen	12.80%
" " 150-mesh "	47.50%
" " 200-mesh "	23.50%
Passed a 200-mesh "	16.20%

PRODUCT FROM NO. 4 TANK.

Stopped on 150-mesh screen	16.25%
" " 200-mesh "	31.25%
Passed a 200-mesh "	52.50%

PRODUCT FROM NO. 5 TANK.

Stopped on a 200-mesh screen	22.50%
Passed a 200-mesh "	77.50%

PRODUCT FROM NO. 6 TANK.

Stopped on a 200-mesh screen	1.25%
Passed a 200-mesh "	98.75%

On comparing the classified material from a series of seven tanks at the Daly-Judge mill, the material sprinkled on plate glass, the relative size of particles may be distinguished by the eye. While the entire product is fine enough to remain in suspension in a strong current of water, yet the system of tanks is able to make seven distinct classes, readily discernible to the naked eye.

Accompanying the classified feed going to each table, there is a certain amount of slime water—for though the outlet (13) is valved, yet it is quite necessary that sufficient water accompany the pulp to give the same the right consistency. From each of the first five fine tables there is made a finished concentrate, a middling, a tailing rejection and a recovery of the slime water. The middling product and the slime water—the two taken from opposite ends of the table—drop into a common launder, conducting them to a centrifugal pump, by means of which they are returned to the cylinder of the first tank of the series to be resettled and reclassified. While the middlings from all the tables are returned together, yet the series of tanks has no trouble in reclassifying this middling product the second time, for when any middling particle reaches the current, which has not the power to lift it, it again settles and is again conveyed to the table for working. The slime water from the last two tables is not returned with the middlings from these tables, but is caught up by itself and passed over two Wilfley slimers, set tandem. By thus diverting this slime water, virtually nine classified products are made. A Wilfley slimer operating on this material at the Daly-Judge mill showed the following results:

Head sample assayed	5.5% Pb.
Tailings "	1.9% Pb.
Concentrates "	35.5% Pb.

This on material every particle of which is the undersize of a 250-mesh screen. One slimer is able to make a ton of the above concentrates every twenty-four hours from a class of material too fine to even settle on the linoleum cover of the standard Wilfley table.

At the tailings plant of the Daly-West two of these slimers will be set tandem, the second machine treating the tailings from the first. It is believed, but still remains to be proven, that three slimers, the third machine treating the tailings from the second, will pay well on the investment. Where two of these slimers are used, the entire tailings of the first machine do not pass over the second, but only that portion of the tailings that leaves the slimer before the introduction of wash water; thus each slimer treats a different class of material, the first machine making a concentrate from the coarser particles, and each succeeding machine handling a finer grade of material. When using slimers in series, each succeeding machine is set flatter, run slower and with less stroke, thus increasing each machine's capability for concentrating an increasingly finer grade of slimes.

Before bringing this article to a close, there are a few important points that the writer especially desires to emphasize:

That a system of tanks, once installed, can be kept in continued service for years without any repairs.

That the manner of delivering the classified feed from the tanks to the tables is such that, when the valve is once properly set, but little attention need be given to the same.

That the tables will receive their feed for hours without the feed valve being changed.

That by classifying the fine material and delivering the same to the concentrating tables, with only the right amount of water, as high a saving can be effected from the fine material as from any of the coarser mill products.

That a large middling product can be constantly returned from each fine table, thus making a high-grade concentrate and a poor tailing rejection.

That the system separates the slimes from all coarser products, and delivers them to the Wilfley slimers with no excess of water, thus making it possible to produce a clean concentrate and effect a good saving.

That a jig concentrator, handling 400 tons a day, can do so on less than 100 gallons of water per minute.

That the system makes it possible to effect a high saving by concentration.

For the Miners.

A publication that will be of practical interest to the mining world is a bulletin (No. 225) of about 400 pages which the United States Geological Survey expects to have ready for distribution before May 1. It is entitled "Contributions to Economic Geology, 1903," and is the second publication of its kind by the Survey. It has been prepared under the supervision of C. W. Hayes and S. F. Emmons, and the contributors include about thirty of the Survey's best known geologists. The bulletin will contain more than fifty short articles, which indicate the work of these men during 1903 in various widely scattered fields of economic inquiry.

A hint of the bulletin's contents will give an idea of its scope. Gold and silver are represented by the following articles: J. M. Boutwell describes the Park City, Utah, ores; A. H. Brooks the placer gold of Alaska; F. H. Moffit the placers of Seward peninsula; L. M. Prindle the Fairbanks placer district of Alaska; A. C. Spencer writes on gold near Juneau, Alaska; C. W. Wright on the Porcupine district, Alaska; G. O. Smith on gold in Maine and Vermont; J. E. Spurr on the Tonopah and Silver Peak districts of Nevada, and H. F. Bain on Wichita, Okla., gold.

A. J. Collier's article on Alaska tin is the only contribution concerning that interesting metal.

Copper is represented by W. H. Weed's paper on New Jersey copper, J. S. Watson's article on Vermont copper, and J. S. Diller's discussion of the geology and resources of the Redding quadrangle, California.

Lead and zinc deposits in Illinois are described by H. F. Bain and zinc in east Tennessee by A. Keith.

Iron is represented by two contributions from C. K. Leith, one on Utah iron ores and one on the iron ores of the Lake Superior district, and by an article from J. M. Bontwell on the iron ores of the Uinta mountains of Utah.

Numerous papers on coal are included in the bulletin. M. R. Campbell writes on Arizona and West Virginia coals. G. H. Ashley contributes a paper on Cumberland Gap coals. C. A. Fisher writes on coal of the Big Horn basin of northwestern Wyoming, J. E. Spurr on Nevada coal, E. F. Burchard on lignite in Dakota county, Nebraska, and J. S. Burrows on Pennsylvania coal. R. W. Stone discusses the Elder Ridge coal fields of Pennsylvania.

Four papers on oil and gas fields are included in the bulletin, namely: Alaska oil by G. C. Martin; the oil fields of Boulder, Colo., by N. M. Fenneman; the Hymer gas pool of Clinton county, Pa., by M. L. Fuller; and oil and gas in Green county, Pa., by R. W. Stone.

Stone is represented by E. C. Eckel's paper on slate in Utah and California, G. W. Stose's article on limestone in Pennsylvania and West Virginia, and T. N. Dales's contribution on the slates of Arkansas.

The clays of western Pennsylvania are discussed by L. H. Woolsey.

Cement in Virginia is discussed by C. Catlett, cement in Pennsylvania by E. C. Eckel, and cement in Alaska by E. A. Smith.

Sulphur receives the attention of three contributors: G. I. Adams describes the Rabbit Hole sulphur mine in Nevada, J. E. Spurr writes about sulphur and alum in Nevada, and G. B. Richardson has an article on sulphur, salt and petroleum in Texas.

Miscellaneous features of the bulletin are J. M. Boutwell's article on gypsum in Utah, E. C. Eckel's

paper on salt in Utah and California, H. F. Bain's description of the fluorspar of southern Illinois, J. E. Kemp's discussion of the graphite deposits of New York, and G. W. Stose's article on the barite of Pennsylvania.

The bulletin will be published for gratuitous distribution.

Canvas Tables.*

Written by H. P. Stow.

The canvas table I shall discuss is different from any other I have ever seen, is manipulated quite differently, and is the result of about twelve years' experimenting, and I hope to demonstrate to you the advantages of the table as used by me.

The ore (quartz) is crushed by stamps and run over Frue vanners — two 4-foot machines to each five stamps—before running onto the canvas tables. No. 7 slot-punched screens are used and the lighter stamps average 2½ tons, the heavier ones 3 tons, per day of twenty-four hours. There is about 2% sulphurets in the ore—iron pyrites exclusively.

The pulp is run from the vanners to the table in launders, a box of any convenient size being used, say 8x8 inches, which widens out before reaching the table to permit a number of small launders to branch off from it, these in turn branching so as to give one launder to every two canvas strips.

At the head of these smaller launders, and also of the one widened out, are placed movable fingers which shift the pulp, thereby equalizing the amount of pulp flowing through the last launders into the distributing box at the head of the canvas.

The canvas table is made up of a series of strips 22 inches wide by 80 feet long, and I find three such strips a satisfactory number for each five stamps, the stamps crushing from 2½ to 3 tons of ore per twenty-four hours. The table is built with great care, the joists—2x8 inches, set 18 inches apart—being laid on a solid foundation, and made perfectly level crosswise, but so as to give a grade of 1 inch in 12 inches lengthwise of the table.

The floor of the table itself is made of 1¼x22-inch by 20-foot boards, of the best No. 2 material, surfaced on one side. Loose knots must be cut out and a solid piece mortised in.

It is better to have the flooring as green as possible to minimize swelling, and the boards should be laid with a small space between them, say ⅛ inch, to allow for swelling. The head of the table is made flat and level for the distributing and clear water boxes. At the head of the table and on this flat platform, running its full width, and having no partitions in it, is the distributing box, made of 1¼-inch material, 8 inches deep, 8 inches on the bottom and 12 inches wide on the top. It has no cover, but placed on top of it, resting on 2-inch cleats, is the clear water box, likewise running the full width of the table, made of 1-inch stuff, 8x8 inches.

In the front of the distributing box 1¼-inch holes are bored about 1½ inch above the level of the table, and in the center of each strip or sluice. A wooden button, about 4 inches long and 2½ inches wide, is screwed onto the side of the box in such a position that it will close and open the hole as desired to regulate the pulp to flow onto the sluice. The best arrangement for the launders described above is to bring them over the top of the distributing box, and so arranged that they spill into it opposite the division between two sluices. If the launders spilled opposite the hole in the distributing box, it would cause too much pulp to flow onto that sluice. A 1-inch hole is bored in the clear water box directly above the hole in the distributing box, and a little sliding gate of thin board is used to shut off the water, the gate being placed inside the box. A piece of leather or rubber is tacked loosely over the hole to break the force of the water, and if properly put on it gives a fan-tail stream, distributing the clear water evenly over the sluice. It requires about 2 inches of clear water for each table. A tailing sluice is built under the lower end of the table and should be at least 1 foot below the level of the table at its highest end, to insure a free discharge of the tailings. At a distance of 6 inches from the end of the table, and 4 inches below the level of it, is placed the concentrator box in two sections and carrying them out as an "ell" in the center to the outside of the building. A platform is built about 6 feet deep and running the full width of the table, and just even with the top of the concentrator box, coming up flush with it, and is necessary for room for the workmen and to hold a secondary box into which the concentrates are shoveled when cleaning up. Ten-O duck 22 inches wide is the canvas used. Do not misunderstand me and confound 10-O duck with 10-ounce duck. Ten-O is very heavy and coarse, and the old hydraulic miners will understand what I mean, as they used to make hose of it. The canvas is cut square and tacked at the head of the sluice tight up to the distributing box, 8 or 10-ounce tacks being used. It is tacked across its width and down the sides about 15 inches, which is all that is necessary.

The roll of canvas is then rolled down the sluice and carried onto the platform, but is not yet cut off. A clamp, similar to one-half of the clamps used for tightening belts when lacing, is then bolted onto the canvas near the end of the sluice, making sure to get the clamp square with the canvas, and a small block and tackle fastened to the clamp and a cleat on the platform, directly opposite the sluice, the tackle tightened, stretching the canvas enough to make it lay smoothly. Before fastening the lower end of the canvas it is well to walk up the sluices and raise the canvas by its edges two or three times along its length, which insures its being smooth and taking its proper place on the sluice.

The sluice being 22 inches wide and the canvas the same, it is easily adjusted and made straight. The canvas being in its proper place, it is now tacked down at the bottom for about 15 inches on each side and is turned over the end of the board and tacked there, rather than on the top of the board, the tack heads being objectionable if on the face of the canvas.

The canvas now being tacked down at the bottom, it can be cut off, being sure to cut it square, and leaving just enough to lap over the edge of the board where it is tacked on after being cut off. The clamp is then removed from the roll of canvas, the latter carried up to the head of the next sluice and the operation repeated. The rolls contain from 64 to 66 yards, so one roll covers three sluices, with some left over—which, however, is not wasted. After all the sluices are covered with canvas, strips of wood are nailed down between them, one strip covering the edges of two canvas strips, making a complete division and confining the pulp within its proper limits. These strips are sawed from pieces 2x2 inches, the cut being taken diagonally, making a triangular strip, which is then planed on all three sides and nailed down on its widest side. Six-penny nails are sufficient and should be put in alternately about 1 foot apart. This fastens the canvas down firmly and explains why it is only necessary to tack the canvas at the head and tail of the sluice. These strips, of course, run the full length of the sluice and should project at the foot about 1 inch. An apron made of 12 inches of the canvas is tacked onto a thin strip of wood 22 inches long and 1¼ inch wide and beveled on one edge. The strip is then nailed onto the end of the sluice, the beveled edge up and the canvas side next the end of the board, the flap being then turned over the strip and allowed to hang down onto the tail sluice. The apron is nailed onto the sluice just flush with the canvas, so as not to make a riffle.

The building covering the table should be a well-built structure and should be built on a separate foundation from that of the table, so that, should it settle, it will not cause the table to get "out of true," and the table, being on its own foundation, can be leveled up at will. It costs practically no more to build the building with trusses and without center posts, which are very much in the way.

The pulp coming from the vanners runs through the launders, where it is split up as evenly as possible, as above described, one final launder feeding two sluices.

The ideal flow of the pulp is a wave motion, which rolls the grains of sand over and over and brings the sulphurets in contact with the surface of the canvas. Only experience and assays of the tailings and concentrates will tell how long to allow the pulp to flow over the canvas before cleaning it up.

The longer the pulp runs over it the better, provided there is no loss in the tailings. I use two tables like the one I have described, there being twenty-four sluices in one and twenty-five in the other, and when the pulp from eighty stamps ran over them (an average of 5200 tons per month) the upper canvas was swept three times in twenty-four hours and the lower twice. All the pulp ran over the upper canvas, and then over the lower one. The pulp is turned off the sluice by closing the button over the hole in the distributing box, and the sliding gate in the clear water box opened and sufficient clear water run on to wash the sand off. If too little clear water is used it takes too long to wash off the sand, and if too much it causes the sulphurets to become dislodged, thereby causing a loss.

The attendant uses a kind of paddle made by fastening a stick for a handle onto a thin piece of board 24 inches long and 2 inches wide, and after turning the pulp off and the clear water on he follows the last of the sand down and by gently putting the paddle down on the canvas throws the clear water to one side or the other, thereby increasing the current and dislodging any sand that adheres too firmly. After the sand is all washed off the apron is raised up and the end placed in the concentrator box, the edges of the apron being turned up, making sides which direct the concentrates into the box and prevents their spilling over and being lost. The apron being set, the attendant takes his broom and, going to the head of the sluice, turns on more clear water and sweeps it down, making even strokes of sufficient weight to clean off the canvas, and yet not to sweep absolutely clean, for reasons to be explained later on. Having swept down one sluice, the apron is lifted out of the concentrator box and then the clear water is turned off and the pulp turned on. The pulp being turned off the next sluice and the clear water turned on, the operation is repeated until all the sluices are swept. The operation took about three hours for each table by men experienced in the work.

Outside of the building and below the concentrator box is set a series of settling boxes, made of 1x12x16-inch, and arranged side by side, the opening from one box to the other being at alternate ends. The surface of the water stands above the opening from one box into the other, in order that the particles of floating sulphurets will have to dip down and get wet in passing from one box to another, which causes them to settle. Naturally, these settling boxes are set perfectly level. The end of the concentrator box is cut down on top some, so the water will overflow from it into the settling boxes. Holes are bored into the ends of the concentrator and settling boxes at varying heights to facilitate drawing off the water when cleaning them up.

(To be continued.)

A New Power Hammer.

Herewith is illustrated what its maker calls the "Little Demon" power hammer, which is designed to furnish at a low price a labor-saving device that will prove economical to mine owners and shop men who have use for a machiue that, by the simple pressure of the lever shown in the picture, can strike 250 blows per minute, a blow heavier than that from a blacksmith's sledgehammer. For many forms of special work, it is claimed by its manufacturers to be of unusual value.

"Little Demon" Power Hammer.

It stands 6½ feet high, is made almost entirely of steel, and weighs 800 pounds. The hammer bead is made of fine cast steel. The manuer of attaching it to the heavy spring does away with the leather strap, making it most convenient. One set of dies, made of forged steel, are furnished with each hammer. It is made and supplied by the J. C. Howlett Machine Works, 256 Fremont street, San Francisco, Cal.

Alaska Assessment Work.

To the Editor:—In your issue of January 2nd, page 2, you say that "a petition from Alaska to several senators asks that the requirement of annual assessment work be removed" (giving the substance), and make some very just comment thereon. The fact may be that such a request was made to some senators. I have lived in Alaska for ten years and have been actively engaged in mining during most of that time as manager, superintendent or in the development of claims, and have never heard a real miner mention favoring such a move, nor have I heard at all of the instance you mention. I presume that request came from the Yukon district or from some district in the far north. The point I wish to make is that the news published relating to Alaska is too vague and indefinite. Such a petition coming from York or any other vicinity in that part ought not to be confounded with a district 1500 miles to the southeast of it, or vice versa. Different parts of Alaska are as unlike as are Idaho and the Sacramento valley, and much farther apart. The fact is that Alaska ought to be divided into three separate territories, but by a careful discrimination such a great journal as the Mining and Scientific Press can do much to benefit this vast and varied scope of country.

H. W. Mellen.

Coppermount, Alaska, Feb. 29.

Diamond workers are divided into cutters, splitters and polishers. There are about 9000 people engaged in this industry in Amsterdam. The number of factories is 64, with 7400 mills. For ten hours' daily work in diamond factories the weekly wages are:

Splitters	$14 07 to $20 10
Cutters	10 05 to 14 07
Verstellers	10 05 to 14 07
Polishers	10 05 to 14 07

A Proposed Filter Press Slimes Plant.*

Written by FRANCIS L. BOSQUI.

The following paper embodies a report which I made on the filter press treatment of slimes at the Liberty Bell mine, Telluride, Colo. At the time this report was submitted the management deemed it wiser to defer the installation of so costly a plant as the one required, in the hope that the many investigators in the field might soon evolve a cheaper and more perfect method of slimes treatment, and one better suited to the conditions at Telluride.

The Liberty Bell ore consists essentially of quartz aud clay, with iron pyrite disseminated through the quartz in very fine particles. There is considerable iron and manganese stain in some of the ore, the latter especially in the clays, which are sometimes quite black. Occasionally particles of galena, zincblende, gray copper and few other minerals are seen, but they are comparatively rare, and not in sufficient quantity to affect considerations of treatment. Free gold is occasionally seen in the quartz, and one or two instances of wire silver have been observed.

The milling plant consists of an 80-stamp amalgamating mill, which crushes through 20-mesh screens; twenty Wilfley concentrating tables, taking out, in iron sulphides, about 2% of the total ore crushed; and a cyanide plant consisting of two tiers of 33-foot vats, five in each tier, fed by revolving pipe distributers. The slimes overflow from the upper settling tanks through gates with adjustable outlets, and thence to a large canvas plant, which effects only a small saving. This slimes product, of which about 100 tons escape per day (or 38% of the total ore crushed), consists of about 3% dry solids. Of this, approximately 93% will pass a 200-mesh screen. The slimes range in value between $3.90 and $4.87 per ton, the values being about equally distributed between gold and silver. The actual averages for ore and slimes during the years 1900-01, 1901-02, 1902-03—using the market values of silver for the respective years—were as follows:

Year.	Value of Ore Milled, Per Ton.	Value of Slimes, Per Ton.	Value of Sands, Per Ton.
1900–1901	$8.00	$3.90	$2 91
1901–1902	8.13	4.05	2 78
1902–1903	9.55	4.87	3.24

The decantation method of slimes treatment, as practiced in South Africa, was abandoned after a fair trial, for the following reasons: The impossibility of settling the slimes to a suitable consistency within a reasonable time, even with the aid of lime; the enormous plant made necessary by the retarded settling and the slow dissolution of the silver; and the high consumption of cyanide from the successive dilutions of the strong solution required for the silver. The only alternative was the adoption of the filter press method. This, however, for so large a capacity, involved a heavy outlay for presses, it having been found necessary to use a primary battery to remove the bulk of water from the slimes.

In the experiments that followed, and in the estimates made on cost of treatment and installation, the data and practice of certain filter press plants now operating in Australia were used as a working basis, modified as the conditions at Telluride required.

To those who have followed the development of filter pressing in Australia, it is evident that this branch of cyaniding has reached a state of high efficiency there. But the over-sanguine metallurgist who is apt to be unduly captivated by the attractions of the new process, and lured by the plausibilities of exploiting concerns who control "improvements" and patents, should be reminded that in Australia filter pressing was evolved from strikingly unique local conditions—or, rather, from a happy conjunction of favorable conditions. I think this may be admitted without depreciating the achievements of those who are responsible for the success of the process. In the Australian ores there is little or no silver to contend with; the slimes are of that permeable sort which admit of rapid operations in the press; the gold exists in a state favorable to quick and satisfactory extraction, or is rendered so by roasting; and, most important of all, the material is high grade, and can bear a high cost of treatment by a process which happens to be the cheapest and only possible one for those fields. But it is doubtful if filter presses will ever solve the problem of the cheap treatment of low-grade slimes. It is generally allowed that the large filter press, as at present constructed, is au unsatisfactory machine. Its first cost is heavy, especially if transported any distance (a press holding a 7-ton charge weighs approximately 20 tons); it is a clumsy machine to handle, and an expensive one to operate. Yet, imperfect as it is, there is nothing just now to replace it. Managers perplexed with low-grade slime problems can do little more than experimeut in the hope of finding something better, or at least wait until somebody else does. It seems not altogether improbable that with so mauy investigators at work on the problem we may soon hear of a slimes process which will possess the great desiderata—high efficiency, comparative cheapness of installation, and low cost of operation.

The slimes at present overflowing from the cyanide tanks at the Liberty Bell mill are principally of clay, and, as already stated, extremely fine. With a system of pointed boxes and large 40-foot settler vats, the experiments indicated that the slimes could not be settled in forty-eight hours to a sludge containing less than 80% water. An experimental filter press plant was installed and operated in the following mauner: A settler vat 5.5 feet deep and 8 feet in diameter was filled by a stream cut out of the total mill flow, equivalent to 2.5 gallons per minute. Into this stream milk of lime was fed in the proportion of 20 pounds of lime to 1 tou of slimes. The vat required about twelve hours to fill, and then overflowed clear water for another twelve hours. At the twenty-fourth hour the slimes commenced to overflow, and the stream was shut off. The vat charge was then allowed to stand for twenty-four hours, the resultant pulp consisting of 15% solids. This pulp was then agitated and fed into a small monteju, whence it was forced by compressed air into a 24-inch center-feed, recess-plate press of nineteeu plates. It took about five montejus to make a charge in the press. The filling was, therefore, intermittent, and the time required for the various emptyings of the montejus was five, fifteen, thirty, fifty and eighty minutes, respectively, or a total of about three hours. The pressure was started at about 20 pounds and reached 80 pounds at the third monteju charge, continuing at 80 pounds to the end. The resultant cake on each side of the plate was only $\frac{3}{8}$ inch thick. The water in the cake was then displaced by cyanide solutiou (.3%), which took from one to one and five-tenths hours. The displacemeut was slow and imperfect, and the effluent liquor, until it reached standard strength, constituted a weak solution which was subsequently used for displacement in the second pressing. The effluent solution was tested constantly by titration as the solutiou was forced in, and this, together with the results of sampling the discharged cake, determined the displacement. The discharged cake contained from 30% to 40% moisture. It was fed into a muller with strong solution and flowed thence to an extractor vat 5 feet in diameter and 6 feet deep, where about 1 pound of lime per ton of slimes was added to maintain the alkalinity. This pulp, containing 20% of dry solids, was agitated with air at intervals of five-tenths hour for seventy-two hours, beginning when the pulp first flowed into the vat, and ending when the last was drawn off. It was then forced through the press again at about the same rate and pressure as before. The strong solution remaining in the cake was displaced by the weak solution above referred to, and about 1.2 pound of cyanide per ton of dry slime was left in the cake when discharged. About 0.5 pound of cyanide was lost in consumption during contact, making the total lost and consumed 1.7 pound. All solutions were run through zinc boxes and the zinc was finally reduced as a check. In this small plant a total of 7.7 tons (dry) was treated of an average value of $3.84 (silver estimated at $0.40 per ounce). The extraction by bullion yield was 74.5%. As these tests were made under rather adverse conditions, it would be reasonable to expect a somewhat higher extraction in practice, and in the followiug calculations 75% will be assumed as the probable working extraction from the slimes.

The mode of operating a large plant was to be as follows: The slimes product, after addition of lime, to be divided between twenty pointed boxes, 5 feet deep, 5 feet wide and 20 feet loug, with constant underflow and overflow. Experiments indicated that this would eliminate about 50% of the water. Possibly a second series of boxes might be added to settle the pulp further. The final underflow was to be led to settler vats 40 feet in diameter and 20 feet deep, of which there were to be three in number, so that each vatful of slimes would have three days between the beginuing of filling and the end of emptying. In these vats, by settling, decantation, and possibly by the aid of filtering, it was thought that the moisture in the final pulp might be reduced to 75%. All of the clear water was to be pumped back and reused in the mill. These settler vats were to be provided with agitating apparatus to prevent settling and irregular supply to the presses during the process of press filling. From the bottoms of these vats several 8-inch discharge pipes were to lead to the pumps, the latter to be a specially designed modification of the Gould triplex plunger pattern, with ball valves, aud provided with a water flushing device to prevent erosion of the plungers. The pulp was to be pumped through a 4-inch pipe to a pressure tank on a hill behind the mill, the tank to be 10 feet in diameter and 20 feet high, the distance pumped to be about 400 feet aud the elevation about 180 feet, insuring 80 pounds pressure in the presses. The presses were to be fed directly from this tauk. In practice it was proposed to pump directly into the press and pipe column, and the tank on the hill was to serve merely to maintain a constant pressure—to reinforce the pump during the beginning of press filling, and later to act as a safety valve in case the pressure should exceed the limit. Some adjustment of this kind would be necessary, because the pumps were to be driven by belt and motor at constant speed, while the press would take a variable amount per minute, according to the stage of filling. These pressure tauks were to be provided with agitators if found necessary.

Fuel Oil in Roasting for Chlorination.*

Written by E. C. VOORHIES.

In discussing this subject we will first briefly describe the furnace we converted to oil burning, which was the old-style, straight-line reverberatory furnace, size 14 feet wide by 75 feet long, with working doors each side for shifting and stirring the batches or charges. These doors are 6x24 inches in size and are set at regular iutervals along each side of the furnace, with a fire box, grate bars and bridge wall at one end; at the other the dust chamber, damper and smokestack. In preparing this furnace for oil burning we took out the grate bars and bridge wall, and leveled up the fire box with brick and clay to the level of the hearth; we then cut a hole in the fire box end wall, in the center of the width of the furnace, about 12 inches above the hearth, and inserted a sheet iron box or flue, 6x10 inches in size, made of No. 18 iron. This was luted with fire clay to hold it firmly in place. This flue is to supply air to the burner. The burner (we use the American crude oil burner) is set directly above this air space and projects into the furnace so far that the flame, in goiug from the end of the burner, does not impinge upon any of the brick work.

Near the end of the furnace a small 4 H. P. steam boiler was erected for supplying steam to the oil pump, and to the burner for heating and atomizing the oil.

The ordinary oil pump is used for pumping the oil and is set in the usual manner. The oil and steam pipes leading from the pump and the boiler to the burner are covered with asbestos to maintain the heat in each as much as possible. The burner is connected to these pipes with brass uuiou couplings, which are preferable to other kinds, as they have ground joints and do not leak; they are also interchangeable when you wish to change burners, which becomes ofteu necessary owing to the iutense heat to which the burner is subjected, and only being used a part of the time the oil carbonizes to some extent in the burner, and it has to be cleaned out occasionally, for which reasou we always have an extra burner on hand.

We find we get the best results by keeping the steam pressure from 90 to 100 pounds and the oil pressure at 50 pounds.

By proper regulation of the steam and oil a flame can be thrown into the furnace 30 to 33 feet long without any blow-pipe action. The appearance of the burner when it is properly regulated, looking at it from the peepholes or doors on the sides of the furnace, is that of a brown fog coming out of the burner, and the gases do not take fire until they reach a distance of 4 or 5 feet from the burner, when they ignite into an easy rolling flame, which rolls along the furnace in all directious without noise or disturbance, and makes an ideal flame for this purpose—the typical reverberatory flame. The flame can be regulated easily by the admission of air through the side doors, so that any particular part of the furnace may be kept at a higher temperature than another part, by allowing the cold air to enter the side doors when it is desired to reduce the temperature.

When a charge of sulphurets is sufficiently desulphurized to have the heat increased the charge can be heated hot enough to draw from the furnace in about forty minutes, while with the use of wood to get the same heat would take from two and one-half to three and one-half hours. In that way we gain a sufficient amount of time during the twenty-four hours to increase the capacity of the roasting furnace, at least one-third. The furnace here described was capable of roasting four tons per day with wood for fuel. With oil we can roast six tons and do the work better and control the heat to a much better advantage than is possible when burniug wood.

Our experience has been in the treatment of sulphurets, when using oil for fuel, that the tailings average a little lower in value on the same class and kind of sulphurets than when we used wood for fuel.

Sulphurets from different mines require a somewhat different treatment, owing to the amount of sulphur, arsenic or lime contained iu the ore, but we do not hesitate in the least, from tweuty-six years experience, to say that the use of fuel oil in roasting sulphurets for chlorination purposes is a decided advantage over the use of wood for fuel, as the charges are more uniformly roasted and never overheated, as is often the case with wood fire, and the heat is under absolute control of the workman, for when a charge is finished you want to dispense with the heat, and all that it is necessary to do is to stop the oil pump, blow out the remainiug oil in the burner with live steam, then shut off steam and your oven is theu ready for the next charge; while with wood the finishing hearth is often too hot with the remains of a hot fire for the next charge, making it necessary to open the fireplace door so as to allow it to cool down a little before moving in the next charge; time is gaiued here also.

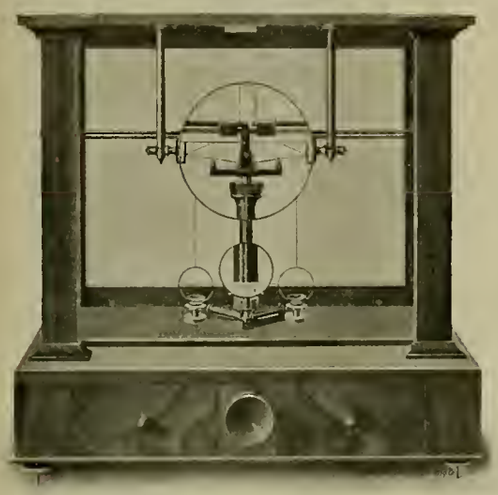
The following is a detailed statement of the amouut of oil and coal used for the treatment of 2647¼ tons of sulphurets: 1290 barrels Bakersfield crude oil, 14° to 16° gravity, was used, which cost, delivered, $1917.63;

*Trans. Cal. Min. Ass'n.

$\frac{11}{100}$ barrel was used per ton of sulphurets treated; the cost of oil per ton of sulphurets was 72 cents; 66.76 tons of coal were used to maintain steam in the boiler used for pumping, heating and atomizing the oil, cost delivered, $867.84, or 35 cents per ton of ore treated, making total cost of fuel for roasting 2647¼ tons of sulphurets, $2785.47, or $1.05 per ton.

A Denver, Colo., Firm.

F. W. Thompson, Denver, Colo., manufacturer of balances, started in business in February, 1896, under the name of Smith & Thompson. At the time they occupied a small place at 2219 Stout St., containing but 600 square feet of floor space, and manufactured but one style of balance. About three years ago Mr. Smith retired from the business, since which time Mr. Thompson has been carrying on the enterprise alone. Several months ago he moved into his present quarters, in the new building at 1717 Arapahoe St., Denver, Colo., where he has over 3500 square feet of floor space, or nearly six times as much as when he started in business eight years ago. He is now manufacturing sixteen different styles of balances, one of which is herewith illustrated. This balance is furnished with either round or cylindrical glass. The cut herewith shows style No. 7 short-beam button balance; sensibility, $\frac{2}{10}$ milligram; length of beam, 4 inches; agate edges and bearings. The beam is made light, to add to its quickness, and is braced for stiffness; it is gilded and has pin graduations. The beam is divided in fifty divisions on each side of center, to enable the operator to place the rider on the center and also to weigh the full milligram with a one milligram rider. It is provided with a double-rider attachment, fall-away pan rests, star adjustment, straight-top beam, skeleton hangers, reading glass for ivory index, plate glass base, levels and leveling screws and polished mahogany case with counterpoised door. Herewith is also illustrated the machine department of the establishment.



Short-Beam Button Balance.

How Bullion is Received, Treated and Paid for at the U. S. Mints.*

Written by Frank Leach, Superintendent U. S. Mint.

We have at San Francisco one of the most important mints in the world, considering its equipment and the volume of coinage annually executed. Until recently it occupied the largest and best building, devoted exclusively to coinage, in the world, but within the past year or so the mint at Philadelphia has moved into a much larger and superior structure; in truth the new mint building at Philadelphia is one of the finest of public buildings now owned by the Government.

We not unfrequently hear the San Francisco institution alluded to as the "branch mint," a term which is not wholly pleasing to the old mint officials, for the reason that the establishment ceased to be a "brauch" years ago, and is now as independent and important as any of the mints of the United States.

Under the old system of the mint service, the Philadelphia mint was the parent institution, and all of the mints of the country were known and established as branches of that mint, and all accounting and reports of the brauch mints were made to the superintendeut of the Philadelphia mint. But in the year 1873 the mint service was reorganized by the establishment of what is known as the Bureau of the Mint, under the Secretary of the Treasury at Washington, at the head of which is an official styled Director of the Mint. The branch mints were made separate and independent mints, and all officials were put on an equality with those of the mint at Philadelphia.

All accounting and reports of operations were from that time made to the Director of the Mint, who, as his title indicates, has immediate charge and direction of the operation of all the mints.

During the course of a year the officers of the San Francisco mint receive several thousand deposits, and probably not more than one iu five hundred of the patrons know, or have much of an idea, of the rules and methods by which the Government officials are controlled in settling with them. The methods and processes of testing and determining the value of gold dust or bullion brought or sent in by depositors to the United States mints, and the systems of assaying, refining, coining, etc., are not at all mysterious or secret in any way. The work is done in the ordinary well-recognized manner, and in such a way as to secure accuracy and promptness in making returns.

After the person bringing bullion to the mint has his metal weighed by the receiving clerk he receives from the register clerk a receipt, which is an acknowledgment that the Government has received from him so many troy ounces, gross weight, and further sets forth that the net value, when ascertained, is to be paid to the depositor on his order. These receipts being negotiable, it is very important that they be not lost, for no depositor can be paid by the cashier without his presenting to that official a receipt from the register of deposits.

In case of a loss of receipt, the depositor is required to give a bond to the superintendent in an amount equal to double the value of the deposit, and also publish an advertisement in a daily paper three times, giving notice of the loss of the document before a duplicate can be issued.

(To be continued.)

Machine Shop of F. W. Thompson, Denver, Colo.

Uniform Bell Signals.

A code of mine bell signals has been issued by State Mine Commissioner White of Colorado, and the large mines of Cripple Creek have been visited and the new signal code posted. The code is as follows:

Bureau of Mines, State of Colorado.

In accordance with the provisions of Sec. 7 of an Act "to regulate the construction, equipment and operation of metalliferous mines, mills and metallurgical plants," I have hereby established the following uniform code of signals to be employed in all mines using hoisting machinery, same to be securely posted in a clear and legible form in the engine room, at the collar of the shaft and at each level station:

SIGNALS.

One bell, hoist.
One bell, stop, if in motion.
Two bells, lower.
Three bells, men on; run slow. Engineers will carefully observe this signal.
Seven bells, accident; hoist or lower by verbal orders, only.
Three-two-one bell, ready to shoot.
Engineers shall, after signal 3-2-1, raise the bucket or cage 2 feet and lower again, and shall remain at his post until final signal is given and command executed.

LEVEL SIGNALS.

1–1 bells	1st level
1–2 bells	2nd level
1–3 bells	3rd level
1–4 bells	4th level
1–5 bells	5th level
2–1 bells	6th level
2–2 bells	7th level
2–3 bells	8th level
2–4 bells	9th level
2–5 bells	10th level
4–1 bells	11th level
4–2 bells	12th level
4–3 bells	13th level
4–4 bells	14th level
4–5 bells	15th level
5–1 bells	16th level
5–2 bells	17th level
5–3 bells	18th level
5–4 bells	19th level
5–5 bells	20th level

RULES GOVERNING SIGNALS.

Rule 1—In giving ordinary signals make strokes on bell at regular intervals. In signals similar to "Ready-to-Shoot" (3–2–1 bells), each bar (– – –) must take the same time as each stroke of bell.

Rule 2—When men are to be hoisted or lowered, give the signal for "Men on, run slow" (3 bells). Men must then get on bucket or cage, then give signal to hoist, or lower (1 or 2 bells).

Rule 3—After signal "Ready to shoot" (3–2–1 bells), engineer must give signal that he is ready to hoist by raising and lowering bucket 2 feet. Miners must then give the signal "Men on" (3 bells), then "Spit fuse," get on bucket or cage and give signal to hoist.

Rule 4—All timbers, tools, etc., "longer than the depth of bucket" or placed within a cage, must be securely lashed before being hoisted or lowered.

Rule 5—Signal of three (3) bells means "Men on; run slow," and nothing in conflict therewith will be allowed. Signals to meet local demands, and not in conflict with the above, may be added by individual operators, but the same must be posted in clear and legible form in connection with the above code.

(Signed.) E. L. White,
Commissioner of Mines.

NOTICE.

Please observe the following, as they are imperative in order to comply with the law:

Don't get on bucket without first seeing that safety chain is properly hooked.

Don't get on cage or bucket without first signalling the engineer. Give three bells, then get on cage or bucket and ring one bell to hoist or two bells to lower.

Don't ride on loaded cage or bucket.

Don't ride on cage or bucket containing tools, timbers or explosives.

Don't load steel or timbers without first landing car or bucket.

Don't attempt to get on or off cage or bucket while in motion.

Don't leave guard rail thrown back.

Don't get in a hurry in signalling engineer; space your bells.

Don't work in ground you consider dangerous. Call your foreman's attention to the condition of the ground.

Don't be careless, thereby endangering the lives of your fellow workmen.

Don't drill in an old hole or "gun."

Don't fail to thoroughly examine ground for missed shots before starting to drill, whether any misses are reported or not.

Don't attempt to pick out a missed shot.

Don't store explosives in excess of one day's supply under ground, but in magazine provided for that purpose.

Don't thaw powder except in powder thawer, which must be provided for that purpose.

Don't use steel or a metal rod of any description for tamping.

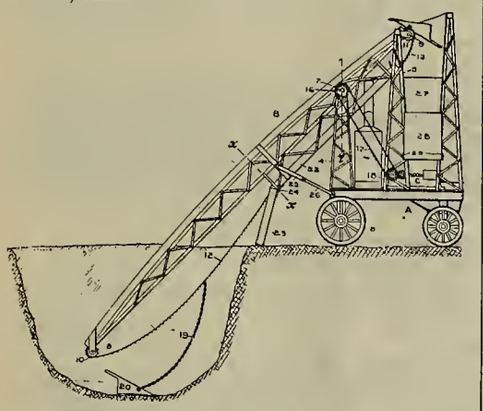
(Signed.) E. L. White,
Commissioner of Mines.

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 15, 1904.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

EXCAVATING MACHINE.—No. 754,480; J. D. Moran, St. Panl, Minn.

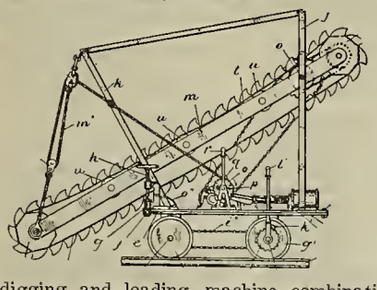


In excavating machine, combination with snitable framework, a downwardly inclined runway having fulcrum support in framework, endless chains carried by runway, scoops connected with chains, guideway supported below upper end of runway, hinged apron at lower end of guideway, discharge chute supported in framework adjacent to inner end of runway, and means for actuating chains.

DRILL OR PUMP ROD GRAPPLE.—No. 754,579; J. Luke, Eskridge, Kaus.

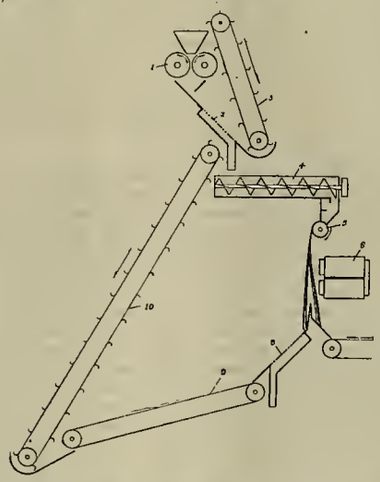
A grappling device consisting of spaced resilient arms terminating in inwardly extending claws and provided with longitndinal slots, and bar movably disposed in slots and provided with notches for engagement with walls of slots to maintain bar in distended position, bar having spaced barbed arms depending therefrom between bar and claws.

DIGGING AND LOADING MACHINE.—No. 754,592; D. McDonald, Bruce Mines, Canada.



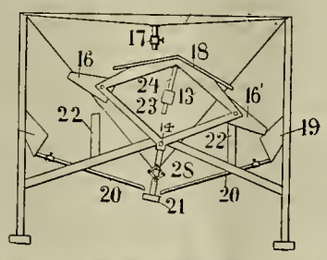
In digging and loading machine combination of movable trnck or platform, swing table mounted thereon, worm shaft for swing table, rack connected to movable truck or platform meshing with worm shaft, pinion shaft, intermeshing bevel pinions mounted on pinion shaft, worm shafts, main frame supported by swing table, carrier frame journaled at one end to main frame, adjustable gear for raising and lowering other end of carrier frame, drums mounted in carrier frame, carrier belt passing around drnms, buckets connected to carrier belt, sprocket wheel for driving carrier belt, motor and means for transmitting motion from motor to sprockct wheel.

PROCESS OF SEPARATING ORES FROM MAGNETIC GANGUE.—No. 754,756; T. A. Edison, Llewellyn Park, N. J.



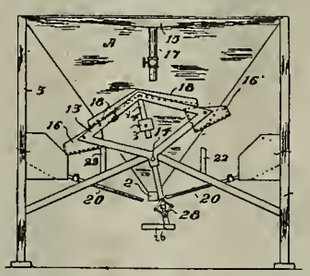
Process treating magnetic ores carrying small proportion of non-magnetic material to be recovered, which consists in grinding ore to sufficient fineness to free non-magnetic particles, in adding thereto predetermined aud larger bulk of coarser non-magnetic material, in subjecting mixture to action of magnetic separator whereby non-magnetic material to be recovered together with added coarser material will be rejected as tailings, and finally in separating added coarser material from original non-magnetic material.

AUTOMATIC ORE AND SLIME SEPARATOR.—No. 754,911; C. Allen, El Paso, Tex.



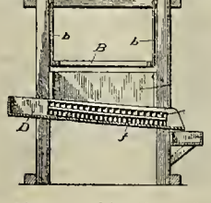
In device of character described, combination with intermittently oscillating tank or hopper hiuged at one end and counterbalanced connections with opposite end tank or hopper having inclined bottom and discharge passage in bottom, of valve in passage connected with counterbalanced connections and operable in unison with oscillations of tank.

AUTOMATIC ORE AND PULP SAMPLER.—No. 754,912; C. Allen, El Paso, Tex.



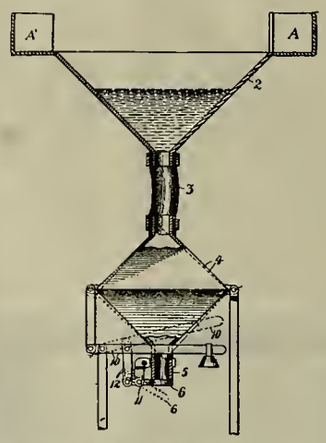
In ore and pulp sampler, tilting tank or hopper having sand ontlet in bottom and separate water outlet, valve in first-named outlet controlled automatically by tiltings of hopper, spout movable across path of sand outlet and operable intermittently by action of discharged water from tank.

GOLD SEPARATOR.—No. 754,657; A. C. La Bud and H. J. Barton, Oakbar, Cal.



In gold separator, combination of slnice box, and plurality of sets of inverted L form riffles therein, lower set of riffles lying on bottom of sluice box and slightly spaced from each other, and upper set directly overlying lower set and having riffles more widely spaced from each other than those of lower set.

AUTOMATIC SILT AND SAND SEPARATOR.—No. 754,732; C. Allen, El Paso, Tex.



In settling apparatus, combination with a conduit section having side opening forming lateral discharge, second conduit section having side opening presented toward discharge of first section, sections being separated from each other, and fluid container forming transverse continnons connection between discharge of one conduit section and inlet of second section, of subjacent tilting tank having communication with container, and having valve controlled sand discharge automatically governable in nnisou with oscillations of tank.

The Globe District of Arizona.

F. L. Ransome of the United States Geological Survey is the author of an illnstrated paper of 168 pages on the geology of the Globe copper district, Arizona. The investigation of this district was begun early in the summer of 1901, when a month was devoted to preliminary reconnaissance and areal mapping of the geology. Work was subsequently resumed in October of the same year and continned to February, 1902. The report is now available as Professional Paper No. 12, and may be obtained, free of charge, on application to the Director of the United States Geological Survey, Washington, D. C.

The area within the Globe quadrangle contains abont 250 square miles. It is sitnated in the southeast-central part of Arizona, between the Gila and Salt rivers, and includes portions of Gila and Pinal counties. It is in the heart of the mountain region of Arizona. The town of Globe, which lies near the eastern edge of the qnadrangle, has a population of about 1500.

The Globe claim, now part of the Old Dominion mine, was the first claim located in the district. That was in 1874. Silver ores were at first the attraction in this region and remained so nntil 1883, when silver mining declined, and the production of silver ores practically ceased in 1889. Abont 1881 copper ore began to attract attention. Up to the close of 1901 the total copper prodnction of the district is estimated at about 120,000,000 ponnds, three-fourths of which came from the Old Dominion mine.

In this paper Mr. Ransome discusses the general geology of the region and the mineralogy, geological occurrence, origin, and age of the ores. He then describes in detail the Old Dominion mine; the group of the United Globe mines, inclnding the Grey, the Buffalo, the Josh Billings, the Big Jonnie, the Buckeye, and the Stonewall mines; other mines in the Globe hills, several miles northwest of Globe; and some mines in schist on the western slope of the Pinal Range.

THE recent advance in the price of zinc ore, though small, about $1.50 per ton, has stimulated the ontpnt in both the Missonri-Kansas and Colorado fields. A few weeks since the Missonri mines were combining to restrict production in an effort to raise the price of ore. Recently blende containing 60% zinc has found a ready market at Joplin at $38.50 per ton. Lead has also advanced in price, and the resnlt is unusnal activity in the lead-zinc mines of the West.

A NEW PETROLEUM BRIQUETTE is being manufactured in Germany. The composition is 1000 parts of crnde petrolenm, 150 parts of soft soap, 150 parts of resin and 300 parts of caustic soda. The mass solidifies at about 120°, when the briqnettes are run through a bath which thinly coats them in such a manner as to make them impervious to the elements and very clean to handle.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ALASKA.

Nome reports say there is more activity in and around Nome in mining than ever before. The creeks are margined by dumps, which are daily increasing in number and size. Early spring cleanups are expected to prove heavy. Machinery has been largely employed during the winter season. Solomon river section has been the scene of much winter work. Operations on Poluk creek have been pushed. The installation of plants will lessen the cost preliminary to work in 1904. Miners on the Inmachuk are meeting with success, according to reports. At the Big Hurrah M. Co.'s plant on the Solomon river forty men have been steadily at work throughout the winter in sinking and drifting. Assessment work on the Irish Hill properties has been increased, the amount not being limited to $100 to the claim. A large amount of work has been done on Hastings creek. They report opening the old channel. An early snowfall was of benefit to the men on Dexter and other creeks. Many who had been unable before the snow to run their thawers or hoists started up under favorable conditions. At the Sugar claim the Pioneer Co. sank a shaft 233 feet deep and ran two levels. This was the first time this system was used in that district. Two pay streaks were reported to have been uncovered by the Pioneer Co., and a pay streak was found where the Bowery claim joins the Sugar claim. On the Dry Creek divide Duggan, Beacb & Connolly have had men working. Pay dirt is reported to have been struck in Newton gulch. Men on Nikkala gulch report their ground is "spotted," but they expect results in the long run.

The Carvey-McNeer group of bench claims, in Nizina section, have been sold for $100,000 to H. V. Winchell et al., says the Valdez News. The property consists of thirteen bench claims on Rex and White gulches. It is reported that the same parties have also taken over the holdings of the Chititu Development Co. Work will be started this season.

Juneau reports say the Mexican and Ready Bullion mines at Treadwell have practically suspended operations owing to a long spell of dry weather. No rain has fallen in southeastern Alaska since February 1st and the wind has blown steadily from the north. A Douglas City report says the timber through the surrounding country has dried out, leaving that town in danger from forest fires. The water system is in bad condition, the water in the pipes having frozen. Water is being retailed in Douglas at $1 a barrel. The water plant at Ketchikan has also been thrown out of use by freezing of the pipes. They are depending on snow water for domestic use. Water is scarce at Juneau and Skagway.

ARIZONA.

Cochise County

W. Kemp, manager of the Copper Belle mines in the Dragoon mountains, near Tombstone, is resuming operations, after a year of idleness.

Maricopa County.

The Chicago-Phœnix M. Co. has been organized in Chicago, Ill., to operate the Nellie Cotton group of claims, near Phœnix. The Nellie Cotton group consists of the Nellie Cotton and Mystic mineral claims, south of the Knob Hill mine. Most of the work has been done on the Nellie Cotton, where there is a showing of sulphide ore. A machinery plant is to be put in, and H. J. Cole of Spokane, Wash., is manager.

Graham County.

I. N. Stevens, superintending development work on the Lezynsky claims, near Longfellow, reports opening up a body of copper glance in the face of the tunnel which is being driven. He has crosscut through concentrating ore for 70 feet. Development work will be continued.

Electric traction has been installed in the Humboldt tunnel of the Arizona C. Co., near Clifton.

Santa Cruz County.

The Senorita Oil Co. has been organized to develop oil lands near Nogales by C. N. Thomas, G. Tuttle, C. R. Brown and P. E. Murray. This company owns land where oil indications have been found, and is arranging to put in drilling machinery.

Yavapai County.

(Special Correspondence).—G. W. Middleton, manager and vice-president of the Bradshaw M. & C. M. & S. Co., is increasing development of that property. Having opened up the ore bodies with shafts and crosscuts and then driven a 1700-foot double track working tunnel 1000 feet below the upper development, he is now building an aerial tramway from the shaft to Middleton station, 1 mile distant, at foot of the mountain. He has taken over and is enlarging the Val Verdo smelter to handle the ore of this mine. The company is a close corporation, J. R. Allen of New York president, and the seveuty claims extend 6 miles in length to ½ mile in width. Trend is along the top of a range of the Bradshaw mountains. Middleton station, on the Bradshaw Mountain Railroad, is 40 miles from Prescott. Along the western line of the property is a porphyry dike, running north and south. East of this are five ledges carrying on the surface values in gold and copper carbonates, and deeper bodies of low-grade sulphide ores. There is a total of 9 miles of pipe on the property, 6000 feet of which carries air from the compressor at the station to the mines on the hill, used to operate the air drills. There will be 1500 feet of surface tram leading to the aerial tram, which will be 4000 feet long, with a fall of 1000 feet. The power generated by the operation of the tram (estimated 30 to 60 H. P.), will be utilized to run a crusher. The tram will have a capacity of 2000 tons daily. Bins are being built at the station and the 50-ton steel hopper-bottomed cars will be loaded directly from the bins. Val Verde smelter is on the Agua Fria river, 22 miles from Middleton. The smelter site includes 1000 acres of land, which gives it control of the river, with abundant water. The slag dump will be extended across the river as a dam. Manager Middleton says the present plans should be worked out within a year, bringing the smelter capacity up to 1750 tons per day, employing 150 men, and giving work to 200 men at the mine. Among other things proposed is a tunnel 1000 feet below the present one with a length of 4000 feet. R. L. Clark is superintendent at the mine.

Middleton, March 19.

(Special Correspondence).—Last week the Button M. Co. was reorganized. The group has been worked intermittently for the past twenty-five years and free-milling ore taken out. W. Button is manager. Sulphide ores are found in deeper workings. There are three shafts, with total of 2000 feet of work, and a 5-stamp mill is up. Manager Button says sixteen tons of ore are treated per day at cost of $1.25 a ton, 1½ cord of wood being used for fuel. Water for mill is pumped from the mine. W. R. Albertson of Worcester, Mass., is president. Development work is being increased and the mill will be put in operation before April 1. It is 7 miles from Crown King.

The Tiger G. Co. owns 4 groups of claims, locally known as the Oro Belle, under management of G. J. Harrington. The groups are the Tiger (7½ claims), the Fleetwood (9), Castle Rock (9), and Standard (6). On these groups are ten separate ledge croppings, most of which have been more or less developed, there being seven tunnels having respectively 90, 100, 200, 660, 675, 673 and 1046 feet length, with numerous crosscuts. Work has been started on a tunnel which will cresscut all of these ledges and run 4660 feet. To depth of 500 feet the ore was free-milling, carrying gold and silver; below that depth it is sulphides. The company's 10-stamp mill is being increased to twenty stamps. This is expected to handle fifty tons per day and yield average of five tons of concentrates. Tables are used in concentration. Principal development work under way is sinking on the Gray Eagle ledge to secure water for mill operation. There is high-grade ore blocked out ready for stoping. The company is considering erection of a smelting plant on Humbug creek, where there is ample water. The company is composed of Illinois men, with G. S. Connelly of Springfield, Ill., president. The properties are in the Bradsbaw mountains, 4 miles frem Crown King, the present terminus of the Bradshaw Mountain Railroad. A sawmill at the camp turns out timbers for the mine and the surrounding forest provides cheap fuel.

Two small properties adjoining the Oro Belle are the New Jersey and Rapid Transit, of which J. C. Bradbury is foreman. The company is tunneling under the former werkings and has again struck the ore shoot. The Rapid Transit reports ore in its tunnel also.

Crown King, March 19.

Several sets of lessees are extracting ore from the Old Peck mine, in the Bradshaw mountains, southeast of Prescott. The main shaft is being unwatered and will be sunk to greater depth. The mill is also being repaired, says J. S. Eagan, manager.

H. La Montayne, manager of the Sultan mine, near Hillside, reports shipping last week a bar of gold bullion valued at $8000, the result of a clean-up after an eighteen-day run of the 10-stamp mill.

At the United Verde smelter at Jerome two 500-ton furnaces and one 250-ton furnace are in full blast.——The Equator smelter, near Jerome, is again in full blast, after a temporary shutdown.

CALIFORNIA.

Amador County.

At the Oneida, near Jackson, the full sixty stamps of the mill are in steady operation.

The 4-stamp mill at the Glenn mine at Volcano is running steadily on ore.——Operations on the Union Flat claim have been suspended until after the heavy rains, owing to tendency of the tunnel to cave while the ground is wet, says the Amador Ledger. The last day's run yielded $47.50 for five men.

The West Penn M. Co. of Pittsburg, Pa., which bought the Wheeler mine (the Ivanhoe) at Plymouth, is preparing to work the Wheeler. This company also proposes buying other properties. C. H. McCaffrey, superintendent, is pumping the water out of the Wheeler mine and will mill 100 tons of ore at the Bay State mill. The shaft is down 125 feet and two drifts are run. The 20-stamp mill was burned down a year ago.

Calaveras County.

An engine and mill has been put in at the Lloyd mine at Central Hill, near San Andreas.

At the Gwin mine at Gwinmine the mill is operating with ninety stamps.

Kern County.

The McKittrick Pipe Line Co. has been organized by A. H. Butler, president of the Dabney Oil Co., et al., to lay a pipe from McKittrick oil field to the sea coast in San Luis Obispo county. The Dabney property at McKittrick is 1150 feet above sea level, and the highest point the line will reach in passing over the range is at 2100 feet elevation, according to the surveys which have been made by W. E. Murray, engineer in charge. Seven pumping stations will be built. The oil averages 18° gravity. The line will be about 90 miles long.

At Amalie the Gold Peak M. Co. continues shipping ore. Manager Laynge says he has bought the Pearl and Emmet mines, giving the company a continuous lead of 12,000 feet on the Zada vein, all of which carries values. The Zada mill, under Manager Cummings, started last week. The company has also put up wire-rope aerial tramways, which are giving satisfaction. The new camp at Sand canyon is being developed.

Mariposa County.

W. B. Sayers, manager of the Roy mine, near Indian Gulch, near Mariposa, says he will put up a 2-stamp mill.

C. C. Burrell of Ellsworth, Me., owning mines at Lewis, treasurer of the White Rock M. Co., near Mariposa, states the company will begin work on the group this spring. He has arranged to put in a gasoline hoist and later an air compressor and machine drills will be used. During the summer, says Burrell, it is expected a smelter will be built of 100 tons daily capacity. E. L. Foster is superintendent.

Nevada County.

The annual report of President J. D. Hague of the North Star M. Co., operating near Grass Valley, shows during the year ending Dec. 31, 1903, the North Star mines produced total value of $736,087.31, at current operating cost of $259,164.39. Of the balance, $237,476.05 was expended on capital accounts; developments, $134,746.63; improvements, $61,987.77; property purchase, $39,772.47. and sundries, $969.18. The total output of the North Star mine during 1903 was 27,395 tons of ore, yielding $732,523.61 ($26.74 per ton), costing for all operating expenses $254,941.40 ($9.30 per ton). The production of 1903 is due in part to the rich ore body opened in 1902, between the 1100-1900-foot east levels, and developed 300 feet farther during 1903 by a winze (all in ore) to the 2300-foot level, from which were produced during past year 10,960 tons of ore, yielding $366,403.73, while from the deeper workings of the mine, opened from the Central shaft, there has been produced $366,119.88, the yield of 16,435 tons. The general average of ore hitherto mined from all the upper levels has been $18 per ton, while past year's product from the deeper workings yielded $22.27 per ton. During 1903 the workings from the Central shaft (vertical) have been extended along several deeper levels, showing continuity of the vein and its general profitable value in depth, says President Hague. Meanwhile the main raise, beginning at bottom of Central shaft (1600 feet vertically below surface), has been driven upward, following vein in good ore, and connected with bottom of upper workings, making one continuously opened mine, 4000 feet deep, measured on dip of vein from surface outcrop to present bottom level. The company owns the Massachusetts Hill and Gold Hill mines adjoining, in direction of dip of North Star vein. During the year $90,792.33 was expended in the North Star mine, and wholly in the Central shaft workings. To this item is not chargeable the cost of mining the ore which was produced from this source in 1903, as it is the sum of outlays made during the year in extending the openings and developing ore for future production. The remaining $43,954.30, charged to development account, has been expended on Gold Hill mine, where prospecting work is in progress, so far without definite results, but giving encouragement toward finding extension of the ore body from which ore was formerly produced. Of the improvement account, $23,702.64 was expended on the Wolf Creek power plant, mainly in addition of a compressor of 300 H. P. Also, $6,957.14 has been expended in improving the North Star 40-stamp mill, and $25,446.48 on account of the new 40-stamp mill, approaching completion near the Central shaft.

The fifteen stamps of El Oro mine of Maybert continue to drop steadily on ore from the Mayflower claim. Setting up of the compressor and the dynamo which is to furnish lights for the mill, hoist and underground has been completed. The work of surface improvements has been temporarily interrupted on account of the storms preventing getting in lumber and other supplies. The flume will be rebuilt during the summer. It is also proposed to add ten more stamps to the mill.

Superintendent J. H. English, of the National Hill group of mines, including the Culbertson, near Gaston Ridge, says with the opening of spring the number of men will be increased and development work will be done. The National Hill is equipped with ten stamps. The mill, hoist, underground workings, boarding house, office and adjacent buildings are lighted by electricity. The National Hill group is in the National Hill vein, being parallel with the vein of the Gaston Ridge and Plumbago, says the Union.

Plumas County.

Dunn Bros. will put in a cyanide plant below their quartz mill at the Mountain Lily mine on the North Fork, near Quincy.

G. Palmer, superintendent of the Colonial M. Co., says the shaft on the gravel claim at Mill Creek, near Quincy, has reached bedrock at depth of 90 feet. This is nearly twice the depth estimated at the beginning of work. A body of gravel was above the bedrock and is reported to yield good prospects. A sump is being put down at the bottom of the shaft. When completed, drilling will begin. The tunnels in the quartz properties, the Mountain Chief and Homestake, which are principal part of Colonial holdings, are being driven to tap lodes which show on the surface.

San Bernardino County.

It is expected the stamp mills at the Ludlow mines at Rochester will be in operation next month. The Chase group will have a stamp mill independent of the other mines, and another mill is being installed for the Roosevelt mine. There are ninety men at work at the Bagdad group, twenty-five at the Chase mine and forty at the Roosevelt. They have been blocking out the ore, running tunnels, timbering shafts. A pipe line is also being laid by the company to convey water to the mines.

Shasta County.

The Northern California Power Co.'s plant at Cow Creek, that will supply electricity to miners near Redding, is expected to be put in operation this week. It will supply power to the Afterthought mine. The plant is supplied by ditch and wooden pipe line, the wooden pipe being made of selected fir, planed concave and iron bound. The ditch is 1236 feet above the machinery. The water goes down through 4-foot pipe, the last joints being 3 feet.

Winthrop reports say the smelter at De Lamar's Bully Hill mine may have to shut down on account of lack of coke. The company has abundance of fuel at Bella Vista, 14 miles away, awaiting shipment by wagon to Bully Hill (Winthrop P. O.), but the storm, which has been in progress since February 3d, has made freighting impossible for several weeks. The season's precipitation was 54.42 inches to the 23d inst.

Trinity County.

At Hall City the bonders of the Williams mine are increasing development work and are arranging to put up a 5-stamp mill. This mine is on the Trinity side of the ridge, near Harrisen gulch.——The first milling of ore on the Eastman Gulch mine, near Weaverville, owned by Hamilton & Goodyear, is reported satisfactory. A sheet of ore has been developed in the mine. The mill is of two stamps.

It is reported the Fairview mine, near Minersville, J. H. Porter superintendent, will have thirty stamps added to the mill.

Tuolumne County.

An agreement was made recently be-

tween W. Sharwood of Soulsbyville and the Grizzly M. Co., whereby the party of the first part will "furnish and build a 20-stamp mill at the Grizzly mine for $20,000, to be paid for from ore extracted from the mine."

Work is progressing at the Longfellow mine at Big Oak Flat. The three-drill air compressor is running and on the 450-foot level east a machine drill is at work breaking ore in the stope. The mill has been put in operation.

R. T. Sorensen has resumed work on the Gold Bug mine, near Big Oak Flat. The heavy rains put a stop to nearly all prospecting work. Sorensen is crosscutting 500 feet from the east line of the Little Wonder.

Superintendent S. E. Riggs of the McAlpine mine, 4 miles from Big Oak Flat, says they have put in electric drills at the mine, which are working satisfactorily.

COLORADO.

(Special Correspondence).—There is an increase in the machinery and supply trade and indications are that it will continue to advance. In different parts of the State chambers of commerce, boards of trade or bureaus of publicity are being organized, the mining and business interests being materially benefited. Conditions in several parts of the State, especially at Telluride and Cripple Creek, are not altogether satisfactory, although at Cripple Creek it is improving. At Telluride the deportation of miners continues.

Several new railroad enterprises are being organized for opening up territory heretofore practically shut off from railroad facilities. These enterprises are mostly electric.

An important feature in the mining industry is the price being paid for zinc and the demand for this metal. In several districts it has been almost impossible to mine at a profit on account of the heavy penalty assessed by the smelters on ore carrying zinc. In Leadville and vicinity ore that was heretofore thrown on the dump on account of the zinc it contained is beginning to have commercial value. Concentrating mills are being designed to handle this class of ore—too low grade to ship to the smelters without concentrating. One property has 180,000 tons of this kind of ore on the dump. In some of the lower levels of the different mines they are not taking the ore out on account of the zinc it contains, but they are now beginning to realize its value.

Denver, March 21.

Boulder County.

At Ward the Myrtle M. & M. Co. has bought the San Blas mine and mill and is remodeling the mill. The company is putting in a fifty-ton ore roaster with fume-saving device. Manager Strong expects to be ready to operate next month.——Smith & Mitchell of the Struggler mine, 3 miles north of Ward, are building a plant at that mine. They have twenty-five men in the mine and mill and expect to start the mill in full operation next month.

Clear Creek County.

(Special Correspondence).—The Ingalls G. M. Co., operating near Idaho Springs, will put in a 30-stamp mill.

Idaho Springs, March 20.

F. A. Babcock, superintendent of the Southern M., M. & D. Co., at Silver Plume, says he will increase development of the Robert E. Lee tunnel in the spring, when they propose putting in a plant to operate with air drills. Ore has been found in the breast of the tunnel that assays in gold and silver.——Nazro & Co. have leased the Frostburg dump and will build a tramway for handling the ores. It will carry the material from the mine direct to the railroad cars.

The number of men at work on the Gold Fissure mine at Empire has been increased to extend prospecting of the acreage within lines of the company. The present workings are mainly confined to the Badger claim (the Gold Fissure), but increase of output by drifting into the adjacent territory covered by the extensions of the Gold Dirt and Tenth Legion veins is proposed. Reserves of lower grade material are being held for introduction of treatment that will be afforded by erection of a plant by the Empire-Gold Bug M. Co., says Manager Clough, of the Gold Bug. The cyanide process will be used. The building will admit of increase of tankage space to accommodate 150 tons per day, while treatment capacity of 100 tons daily will be provided at start.

The Waldorf M. Co. will enlarge the Stevens mill, near Georgetown, to capacity of at least 100 tons per day, and it is said the company will build another for treating ores from the Tobin vein, which shows 4 feet of mineral.——The Hazleton Con. Co. will build a mill for treating ores from the Baltimore tunnel and also from the Santiago mine. An aerial tramway will be built from the Santiago and the ore treated at the mill near the mouth of Baltimore tunnel.——Several other companies, among them being the Corry City, are investigating methods of treatment.

Chaffee County.

(Special Correspondence).—About 15 miles from Salida and 2 miles from Turrett, in the Turrett mining district, the Ethel G. M. Co. has opened up a body of graphite. The vein is 40 feet wide and analyses show marketable values. L. L. Miller, president of the company, is arranging to put in a mill to prepare the material for market. They have one shaft down 60 feet on the vein. The property will be developed extensively the coming summer.

Turrett, March 21.

Dolores County.

The Rockwood-Perkins-Lee-Miller Co., which have a lease upon the United Rico M. Co. group tunnel dump and a number of stopes in the Enterprise mine at Rico, has started up the mill.

Gilpin County.

Shipments of smelting and other ores, mill tailings and concentrates from Black Hawk depot to the Denver smelters and outside points of treatment for the month of February amounted to 202 cars, or 4040 tons, an increase of 160 tons over January.

Twenty men are being worked at the Hamlet mine, in Gregory district, near Central City, by the Hillside M. Co., most of whom are working under tribute. Work is being carried on in the east 365-foot level, and both milling and smelting ores are being taken out. The smelting ore is shipped both to the sampling works and to the Denver smelters, while milling ores are being shipped to three batteries at the local mills at the rate of three cords (128 cubic feet, or 7½ tons per cord) per day. W. H. Simonds is superintendent.——Dalsoglio & Co. of Central City are operating the Dump mine, Gregory district, under lease. They are operating in the 200-foot west level, where they have milling and smelting ore. The last shipment of milling ore brought values of 5½ ounces gold per cord, and the smelting ore has been returning 3 to 6 ounces gold per ton.——W. Mitchell & Sons are preparing to put in a steam plant on their Gulch property, in Lake district, near Central City. They have the shaft down 300 feet and are drifting and stoping in the bottom levels. Both milling and smelting ores are being shipped.

Sinking operations have been completed at the Cook shaft, near Central City, down 1400 feet. It was sunk an additional 500 feet. Manager Thompson has started up the Boston mill, which has been overhauled, dropping twenty-five rapid-drop stamps which are expected to handle between forty and fifty tons per day. The ore will be conveyed to the mill by electric tram line, running through the Bobtail and Bates hill tunnels.

Superintendent A. W. Rucker of the Nevada Con. G. M. & M. Co., near Central City, says the mill is in operation. It has daily capacity of 100 tons and the company expects to keep it running on ores from the King and other mines of its group. Superintendent Rucker will increase his force to 100 men in the mine and mill.

Gunnison County.

The Gunnison Exploration Co. has been organized in Denver by A. T. Morgan, T. J. Zollars, W. H. Sherrod, L. W. Van Dyke and L. G. Schwallenberg to develop and operate holdings in Sherrod and Tomichi districts.

Jefferson County.

(Special Correspondence).—The exhibit of the Colorado School of Mines of Golden at the St. Louis Exposition will be a working assay and metallurgical laboratory. A space of 25x50 feet has been assigned in the Metal Pavilion, opposite the Mines and Metallurgy Building. Equipment will consist of one coal and two gasoline furnaces and necessary accessories, four desks for chemical work and a dust proof balance room inclosed in glass. Besides the practical laboratory work, there will be eight cases for general display. Work will be done by students of the Colorado School of Mines, under direction of a committee of the faculty, consisting of President V. C. Alderson, F. W. Traphagen, professor of metallurgy and assaying, and H. Fleck, professor of chemistry. While regular assays will be made to show general methods of work, it is intended to assay free of charge all specimens that visitors may choose to submit.

Golden, March 21.

Lake County.

Manager Frank Brooks of the Diamond mine, at Leadville, says the Diamond is shipping 100 tons a day, while development work, that is being done in all directions, shows ore. The pay ore being mined shows oxidized iron material, running $18 per ton, with a 20% iron excess, and also a showing of high grade lead ore. The principal work is being done at 1020-foot level; and the main drift at this point is in 600 feet and has entered the Vega ground. The water flow at the Diamond has been reduced, and they are handling 325 gallons per minute. The Diamond has seventy men at work.

Leadville reports say operations at Little Ellen hill are increasing. A strike has been made in the Ollie Reed mine, showing gold, silver and lead. The Silent Friend, near the Ollie Reed, is also producing high-grade ore. Greene Bros., operating near the Treasure Vault, have ore and are making shipments.——F. Ballon has bought the Little Ellen lease and will increase work.——The Valley mine, it is said, has a body of ore in sight and will resume work next month.——It is proposed to drive a tunnel through Mosquito range, going down by the Diamond and the mines of Big Evans gulch.——The owners of the gold mine on Alicante expect to open up the mine in the spring. Six men have been at work all winter getting it in shape.

The Last Chance mine in Horseshoe district, near Leadville, is being operated by the Cerussite M. & M. Co. This company has also bond and lease on the Hilda, Addie, Cato, Cerussite, Wasboe, Anglesite, Big Chief, Iron Chief, Uncle Sam and E Pluribus Unum. The Cerussite placers are owned by them. During the past year they have rebuilt the concentrating mill, putting in machinery, consisting of concentrating tables, crushers and crushing rolls, revolving screens, hydraulic sizers, slime tanks, pumps and settling tanks; also an independent electric lighting plant. It has capacity of 60 tons of ore per day. In the mines work has been devoted for the past three years mostly to development of ore bodies; reserves of ore are being opened up, preparatory to mining on a larger scale as soon as connections are made with south workings from hoisting shafts.——The Peerless Maud, in same section, is being operated by H. Dyatt and producing both smelting and milling ore. This mine, as well as the Cameron, is on southern extension of the Last Chance ore shoot, says the Carbonate Chronicle. Manager Dyatt has completed sinking a new shaft on north end of Peerless Maud, and has opened up a large body of ore, from which he is shipping steadily.——On the Dora Daisy property, 1500 feet east of the Last Chance, on Mt. Sheridan, the tunnel is going ahead.

Las Animas County.

Governor Peabody, on the 22nd inst., declared Las Animas county in state of insurrection, and 380 members of the National Guard were sent to Trinidad and distributed among the coal camps. The soldiers have relieved the mine guards employed by the coal companies at $5 a day each. On arrival, Major Hill placed the entire county under martial law, ordering all saloons, dance halls and other resorts of a questionable character to close at 9 P. M. daily. All citizens having firearms in their possession are ordered to register them with the military authorities, and the sale of firearms and ammunition is forbidden. The mine owners have insisted for several months that they could not get men to operate their properties because non-unionists were afraid to go to work unless afforded military protection. Las Animas county forms the larger part of southern Colorado coal fields.

Mineral County.

Work is under way by the Humphreys M. Co. at Creede to build check dams along the creek for catching tailings from the mill and to allow slimes to settle. These dams will be 7 feet in height and several hundred feet long.

Ouray County.

The Imogene G. M. Co. is working sixteen miners, nine on the Ironton side of the range in the tunnel, and seven sinking a shaft on top of the range south from the old workings of Camp Bird mine, near Ouray. The tunnel is in 600 feet and is headed for the shaft, a distance of 4000 feet. The shaft is down 400 feet. Manager L. B. Jackson of Chicago, Ill., says more men will be put on.——The local smelter management has leased the Silver Bell dump near Ironton and several others, and is waiting for the roads to improve for hauling ore before blowing in. —— The Angel M. Co., on the south slope of White House mountain, has worked a few men during the winter and has a 4-foot body of $25 ore.

Arrangements are being made to open up and resume operations on the San Pedro group, adjoining the Camp Bird. Progress was made last season and the main tunnel is in 1000 feet. There are twenty-seven claims in the group, and it comprises most of the territory between the Camp Bird and the Revenue.

Two pumps have been added to the equipment at the Revenue mine, near Ouray. As soon as the pumps are in operation more miners will be put to work developing new levels from the two shafts on the vein. The mills of the company in Sneffles district will resume. ——Development work on the Governor mine continues steadily. Bodies of ore are exposed in the workings and a 10-stamp mill will be built. W. R. Kramer is manager. —— The number of men on the Portland group, 2 miles east of Ouray, will be increased by twelve men April 1st, says Manager D. Wood of Youngstown, Ohio. Arrangements for continuous development and mining of ore have been made. The second-class product of two cars per week has resumed shipment to the smelter.——The Atlas, a gold producer of Sneffles district, will have a 10-stamp mill as soon as the roads permit hauling. For 500 feet back from the breast of the main tunnel the ore streak averages 3 feet in width, and aside from the small high-grade shoot of gold ore the values between the walls of the vein are stated to make it a milling proposition.

San Juan County.

Work has been resumed on the Hamlet mine, above Eureka, says G. Robin, manager and part owner. The bulk of the ore is milling, and it is proposed to build a mill on the Animas river, below the mine.

The Kendrick & Gelder smelter, near Silverton, will be blown in April 15. This smelter is the property of the San Juan S. & R. Co. and has capacity of 150 tons a day. Superintendent Umbell of the Henrietta mines, of the San Juan S. & R. Co., is increasing number of men at work breaking down and shipping ore. The mine has been developed during past three years by seven levels, raises connecting the same, and drifts and stopes, all in bodies of ore which contain gold, silver, copper and lead values. The Henrietta mine is connected by an aerial tramway with the millsite and railway, capable of handling 500 tons of ore per day, but for the present will only be operated to capacity of smelter of 150 tons daily.

San Miguel County

Operations at the Keystone placer, near Telluride, will be resumed next week, says Manager R. W. Hill.

Summit County.

The 7x7-foot tunnel of the Gold Run M. & M. Co. (the Lightburn tunnel), near Breckenridge, is in 2050 feet. It is to be driven 3000 feet at least for a vein opened from surface by shaft. The tunnel prospects the ground of forty claims of the group.

Teller County.

(Special Correspondence). — The Cow Mountain M. & T. Co., operating on Cow mountain, in Cripple Creek district, has its Deep Rock tunnel in 400 feet, and will shortly put in air compressor and power drills.

Cripple Creek, March 20.

Lessee E. O'Malley & Co., who have a lease on the Hiawatha claim on Beacon hill, Cripple Creek, will put in air drills. They will pipe their air a distance of 700 feet from the El Paso mine. They have sunk the shaft to 70 feet, where ore runs entire width of the shaft. The ore is in a blue quartz, showing specks of sylvanite, says O'Malley.

At the Hot Scotch mine, on Grouse mountain, near Cripple Creek, Smith & Co. have uncovered at grass roots a body of ore, and are planning to build a 30-ton cyanide mill. They will put in rolls of 100 tons daily capacity.

Manager Wright, of the Lincoln mine, at Gillett, is plowing up the wash which yields $4 per ton. The material is thoroughly oxidized and lies in a body 25 feet wide. He is building a cyanide mill for treatment of this material.

The El Paso drainage tunnel at Cripple Creek, according to measurements made by Engineer Jaquith, is discharging 6700 gallons of water per minute. The east lateral, which starts near the El Paso main shaft on Beacon hill, has been driven for 1300 feet. The main water course, however, has not yet been cut. At the present flow, the Mary McKinney and the Elkton, together with all of the mines affected, have been drained for a depth of 50 feet. The mines are now being drained at rate of 10 feet per month.

The Ophelia tunnel (formerly the Smith-Moffat and later known as the Gold Exploration tunnel), is resuming operations. The Ophelia tunnel traverses the district of south Cripple Creek for 2 miles in an easterly direction. The breast is now under crest of Raven hill. There is at least as far to drive yet as there has been done in the past, says the Gazette, it being the intention of the tunnel company to bring the breast of the tunnel when completed to the Victor mine on the east slope of Bull hill and the farthest eastern point of the producing gold area. The tunnel is for transportation of ore and for drainage, the company not owning property in its course aside from that at the portal. In the progress of driving a number of veins belonging to properties en

route have been struck, and by stipulations of contract with the tunnel company the tunnel company will deliver the ore at any point specified by the owners of the property. Laterals will be driven. Water boxes are laid on the floor of the tunnel under the track, on which an air motor is in operation. The tunnel is being operated by three different enterprises composed of New York, Chicago and Boston men, namely, the Cripple Creek & Pueblo Railway Co., the Gold Exploration Co., and the Tunnel & Leasing Co. J. M. Parfet is manager.

Manager F. A. Wright of the Grand Central M. Co., operating between the Stratton's Independence and Gold Coin mines at Victor, is preparing to increase development work. Veins have already been cut, and one is thought to be an extension of that in the Strong mine. The shaft on the Grand Central has been sunk to 500 feet, although little farther development work has been done. It is intended to sink the shaft at least 200 feet deeper and increase exploratory work.

The annual report of President Bernard of the El Paso Con. M. Co., Cripple Creek, says that during early part of last twelve months, there were added to the mining plant two 516 H. P. boilers and a 2000-gallon pump, at total approximate cost of $25,000, and which were ordered prior to the time when it was decided that the drainage tunnel should be driven. Some of the buildings are yet to be completed, which, together with the company's contribution to the drainage tunnel fund, absorbed greater portion of the earnings during that period; the production and development during such time being curtailed owing to energy being exerted in driving and completing this tunnel. The effects from that common water carrier are far-reaching. Those mines which are known to be draining through this tunnel embrace everything in the district with possible exception of the Bull Hill locality, and it is expected this section will ultimately be drained, being indirectly connected with the other water courses. This bore is still being driven northeast with funds which were on hand when the contract with the El Paso Co. expired. He says preliminary surveys have been made for two deeper tunnels, the first of which would penetrate the El Paso at depth of 1200 feet and would be 2¼ miles long, costing approximately $250,000. The second survey is 3¼ miles in length and would cut El Paso 1900 feet from surface or 1300 feet deeper than present deepest workings and at a cost of $500,000, and be completed in three years. Whether a deep tunnel project, or a mutual pumping agreement among the leading companies will be used is not yet decided upon. Production made during year shows increase over the preceding year of 25%. The average grade of the ore is below that of the previous report. Up to Sept. 1, 1903, there was shipped 8720.66 tons of an average of $27.58 per ton. From Sept. 1 until the close of the fiscal year there was shipped 6177.97 tons of an average of $55.50 per ton. Until after completion of drainage tunnel production had been confined to levels above 335 feet, after which perhaps one-half the tonnage came from the lower levels, and about 1000 tons in the last six months was ore from the dump, averaging around $15 per ton.——Development work was much delayed during first seven months of the year, awaiting completion of the drainage tunnel. The present developed ore reserves exceed those of any previous time, and as development proceeds in lower levels they are being increased. The result of 480 feet of drifting in the 600-foot level has shown two bodies of ore for 300 feet of the distance and from which no stoping has yet been done. This ore is in grade from $30 to $150 per ton. On the 490-foot level two ore bodies have been developed, one being main ore shoot in C. K. & N. vein.

IDAHO.

Ada County.

The Statesman reports a strike in the X-Ray tunnel above Boise. This tunnel has been driven 390 feet and the last 90 feet has been in a ledge carrying sulphides. Assays run $3.90 per ton in gold. The ledge at the surface is 200 feet wide. The tunnel is 8x8 feet. Manager C. H. Packenham is preparing to put up a 20-stamp mill with concentrating tables and a cyanide plant, and also a power drill plant, track and cars. The machinery will be operated by electric power.

Blaine County.

At the Valley Creek mine, near Hailey, the 5-stamp mill is running steadily and twenty-five men are at work in the mine.

At Muldoon, near Hailey, three companies will operate, besides prospectors. One of the companies, the Argosy, that bought the Wolters claims, will begin work. Shipments are being made and a concentrator will be built in the fall.——Another of the companies is the Albany, C. Hernsheim of New Orleans, La., F. C. Mandell and M. Greene owners.——F. C. Bradley reports having 3 feet of galena and will make shipments.

Boise County.

C. H. Packenham of Boise, manager of the X-Ray tunnel, in the Black Hornot mining district, says he is arranging to put in a plant for treatment of ore, consisting of a 20-stamp mill, with table concentrators and a cyanide equipment.

Idaho County.

C. F. Macey, manager of the Iron Springs M. Co. in Rapid River district, near Pollock, says arrangements are being made for increase of development work and for building a cyanide plant this summer. He also says they will build a wagon road from Iron Springs to Pollock, the survey for which was completed last fall. A 200-ton mill will be built this season.——Ford Bros. will begin next week logging for their mill at their mining camp at Black lakes. The mill will be started cutting timbers for the cyanide plant to be built this summer by the Gold Coin M. Co. It is expected the machinery for the plant will be on the ground by July 1. It is hoped to have it in operation before snow next winter. The plant will be of 100 tons capacity.

Arrangements are under way and machinery is arriving for a stamp mill and concentrating plant to be put up on the Johnson mine on Rapid river, 8 miles from Pollock. The mine is now owned by J. P. Weyant, F. M. Henninger, H. Boone et al. of Toledo, O.

The Henrietta M. Co. has been organized to work the Irwin bar between Goff and Riggins, says the Grangeville Standard. There are ten men in the company, principally of Payette. The company has expended $5000 on a ditch from the Little Salmon river, which will be completed in time to make a cleanup before high water.——The Pittsburg-Idaho M. Co. will start work on the ditch, which it expects to construct from Lake creek to its property, the Short placer bar, as soon as the roads will permit of moving the sawmill in from Council. The company will build a flume the entire distance. They have built a bridge across the Little Salmon, below Pollock, where they will cross with the machinery.——E. W. Herchberger is working the Auchenvaugh bar, above Lucile. He expects to pipe water across the Salmon river. There are a number of other bars on which prospectors are at work, and flumes and ditches building.

Kootenai County.

Placer mining operations are resuming around Tyson. E. S. Mumford has his ground opened up and sluice boxes ready for use. The ground has been prospected and is reported to show pay dirt from 4 to 16 feet.——E. J. Kelly, manager of the Corbin interests, is preparing to start work, and R. Neil, superintendent of the Tyson Con. Placer Co., expects to start work on the Gold Nugget. These properties are provided with pipes for hydraulic work during high water. Other claims will work on a smaller scale.——The Richmond Co. is continuing work in its shaft.

Owyhee County.

Work will be resumed on Sinker tunnel, near Silver City, owned by Philadelphia, Pa., men.

The Addie mine, near Silver City, has its tunnel nearing the Calaveras ground and reports having struck pay on the vein. The shoot of ore, struck at depth of 450 feet from surface and within 100 feet of the surface workings of the Calaveras, is expected to continue under those workings.——The Trade Dollar Extension Co. is increasing work on two tunnels on its group, east of the Trade Dollar Con. on Florida mountain, and will put in power drills on arrival of the delayed electric transformers.——Sullivan & Noble, on their mines at head of Jacob's gulch, are in ore.——The Afterthought on War Eagle mountain, on which the De Lamar Co. suspended work for the winter on account of difficulty of getting supplies in through the snow, will start up again in the spring.

The American Standard M. Co., organized in Denver, Colo., holding claims in the silver-lead district of South mountain, near Silver City, will start development work next month.

Manager Stevens reports developments satisfactory in the Addie group, near Silver City. At 1400 feet from portal in the tunnel, where the Trook and Jennings vein is supposed to cross the porphyry dike, they have run a tunnel northwest toward surface workings of the Calaveras. They have opened ore assaying $20. The tunnel is still within the Addie fractoni ground. The tunnel will be 400 feet deeper than the deepest work on the Calaveras, which is only 65 feet. A mill will be built and more men are being put on.

Shoshone County.

Wallace reports say that after April 1 canvas plants will be no longer in use in the lead-silver concentrating mills of the Cœur d'Alenes. For some time the Standard mill of the Federal M. & S. Co., near Wallace, has used the only remaining canvas plant in the district. Table concentrators and Frue vanners have been added to the equipment to handle the fines.

KANSAS.

Cherokee County.

Manager Matthews of the Pittsburg Lead & Zinc M. Co., operating the Bonanza and Windsor groups in the Galena-Empire district, says the water is now down in the Bonanza and lots are being leased. The water in the pump shaft is below the 160-foot level, and next week will be down to the bottom, which is 225 feet. The mines on the land will give work for 100 men by that time. The company will put up a 100-ton mill on the Bonanza, near Galena.

The Co-operative M. Co., which has bought the Bert Stair mining ground south of Galena, has been incorporated by W. B. Stone, J. H. McClaren, J. C. Moore, G. Grant and W. E. Stair. Superintendent Stair says the water is out of the ground and the men went to work last week.——The Old Crow mill on the Windsor ground is being repaired and will be ready to grind ore next week, says Superintendent Moll.

At Baxter Springs, it is reported Gerke & Co. of Joplin, Mo., who have leased 160 acres of the J. B. Opperman ground, have entered 25 feet of ruby jack in two separate drill holes. The ore was struck at 90 feet.

MICHIGAN.

Houghton reports say sixteen producing mines at the lake turned out 14,925,000 pounds of refined copper during February, against 16,076,400 pounds in January. The appended table gives the production of the lake mines for the last six months:

Months.	Pounds.
September	15,985,000
October	16,315,000
November	16,980,970
December	17,330,000
January	16,076,400
February	14,925,009

On the basis of 12⅛ cents a pound, the lake production for February was worth $1,865,625. This month's product is expected to show a falling off even from the February figures, owing to the strike at the Copper Range mines. The output of these mines in February was curtailed 50%. The output of the Quincy was nearly double that of the previous month, owing to the settlement of its strike early in February, and this month it should return to its normal rate. There should also be an increase in the Mohawk's production, three heads being in commission at the mill.

Houghton County.

R. C. Pryor has an option on ground adjoining Atlantic's former section 16 and also Isle Royale, near Houghton. These portions are thought to carry the Baltic lode, and their exploration with the diamond drill will prove section 16 and the Isle Royale land adjoining, says the News.

The Isle Royale C. M. Co. is confining work to No. 2 shaft, which is shipping 500 tons of rock per day—enough to keep one head at the mill in operation. There is said to be no prospect of an increased output this year. The working force is 140 men. Three drills are drifting and fourteen stoping. The management is still uncertain about No. 1 shaft, the seat of the fire last fall. A wall of cement and stone is being built at the fourteenth level south. The burned workings will be flooded with water this spring and the wall will keep No. 2 dry.

The Atlantic mine, near Houghton, last week voluntarily raised the pay of trammers $2 and miners $2.50 a month.

Sinking to ninth level is under way in both Nos. 1 and 2 shafts at South Kearsarge branch of Osceola mine, near Calumet. The lowest openings in the South Kearsarge are reported showing satisfactory lode. This portion of the Osceola is comparatively a new mine.

Keweenaw County.

A hoisting engine capable of hoisting from depth of 2000 feet is on the ground for the Mohawk mine, near Allouez. A 60-drill compressor will also be put in. It is expected to be ready for operation by May 1.

The Phœnix Con. C. Co., at Phœnix, report for year ended December 31 last shows receipts from 202,823 pounds of copper sold for 12.613c per pound, $25,582; smelting, freight, cost of marketing copper and all expenses, $12,789; balance, $17,793; expended at mine, $200,826. Owing to delays incident to delivery of supplies and machinery, the company's mill was not put into commission until October 1st last. A severe winter season has interfered with surface work and transportation of rock to mill. The rockhouse at the St. Clair shaft of the Phœnix mine is completed. It is a duplicate of that built at west vein shaft last fall. Sinking in the latter shaft has reached vertical depth of 855 feet. Drifts on the lower levels are opening up copper. The Phœnix is securing thirty-five to forty tons of mass and barrel stuff each month. It is hauled by teams to Calumet and then shipped by rail to the Quincy smelters, where it is refined. The teams take supplies on return trip to mine.

Ontonagon County.

The annual report of the Mass M. Co., operating at Mass City, shows the company produced during 1903 a total of 2,576,447 pounds of copper, which was sold for $343,733, or an average of 13.3 cents a pound. But one stamp was in operation and on half time.

MISSOURI.

Jasper County.

L. J. Stevison is putting up two mills on his lease west of Duenweg.——J. W. Ground proposes building a mill at his mine on the Porto Rico group.——The Miami M. Co., operating on the Porto Rico, will begin construction of a plant at its place next month.——The Shamrock, east of Duenweg, has resumed operations after a four months' shut-down.——Wommack Bros. have begun sinking another shaft near their prospect, east of Duenweg, to be used as an air shaft.

The Wright M. Co., on the Missouri Zinc Fields land, near Webb City, last week reached their ore body with a shaft. They own nine lots. They drilled the lots last October, and at depth of 150 feet went through 20 feet of ore, which is said to assay 52½% zinc. They are sinking the shaft in the ore. This mine is west of the Missouri Pacific track and the Dicky and Black Cat mines. It is owned by J. C. Wright, F. Gilbreath and D. Matbias of Carterville.——T. Coyne is arranging to put up a mill on the South Missouri Z. F. Co.'s land, and has entered into a contract with the Missouri Z. F. Co. to furnish him with electric power to be used at said mill.

J. A. Hardy & Sons are building two mills at their mines at Centerville—one, the Little Diamond, on Center Creek ground; the other, the Osage. Both mills will be of 100 tons capacity and cost $8000 each. They will each be equipped with 100 H. P. boilers and 50 H. P. engines, crushers and rolls. The dirt will be shoveled into the crusher, and will then run over a screen, the fine dirt going direct to the jigs and the coarse dirt to the rolls. After coming from the rolls the dirt will again go over a screen, and the fine dirt to the jigs, and the coarse dirt conveyed to the rolls a second time. Each mill will also be equipped with a sluice table.

The Star mine, on the Zinc Fields lease, near Webb City, will be put in the list of producers again this week, as the air drift has been finished, says C. Hammick, lessee.

The Broker mine is a new development on the Leddy lease at Central City, says the News-Herald. A 24-foot face of jack has been opened up, to clean which a crusher, rolls and steam plant have been added. The owners are P. Leddy, D. Joseph and J. Streeby of Joplin.——H. G. Cook, J. Hennessy et al of Joplin report having made a strike at Galena on the Galena L. & Z. Co. ground. They went into the Cousin Jack shaft and struck a face of ore, all jack.——Stevenson & Bourne have opened up a lead prospect on their lease on the Sol Webb farm, south of Duenweg. In sinking the shaft they went through 30 feet of lead dirt and have begun to drift on it.——W. A. Kirkpatrick, J. M. H. Young, A. H. Hall, J. N. Martin, E. T. Jenkins, A. H. Rogers and J. W. Stephens have incorporated as the Mabel M. Co. at Joplin. The company will build a mill on its lease at Chitwood.

The Zenith mine and mill, near Joplin, are being overhauled to start again, under management of J. Carmean.——A 16-inch air compressor has been set up at the Hoosier mine, operated by F. Nicholson et al.

MONTANA.

Fergus County.

C. M. Goodell of Pbilbrook, W. G. Norman of Lewistown, with Colorado men, have organized the Moccasin Mountain M. & M. Co., and have taken over the Butterfly, Emmett and Wedge claims, south of the Kendall G. M. Co. properties in the North Moccasin district, near Kendall. They will continue development work. A diamond drill will be operated. Later, a mill will be built. The group is so situated that the securing of both water and timber is not difficult.

M. West is contracting on the Denver group on head of Plum creek, on north slope, near Lewiston. Contract has been let for additional 250 feet in the tunnel on the Denver. M. Dunn of Great Falls is part owner. The values of the ore in the Denver group are in free gold. It is

tbought a milling plant will be built this year.

The North Moccasin G. M. Co. is increasing work on its ground between the Kendall and the Barnes-King mines, at Kendall, and a milling plant on these properties is assured for this year. Manager J. H. McCormick of tbe Gold Reef M. Co. of Gilt Edge is preparing to put in a boist to be used on a shaft tbat will be sunk from bottom of gulch in which is located the Kendall mill. J. A. Drake, of the Gold Reef Co., is part owner in the North Moccasin group. The milling plant will have 100 tons daily capacity to begin witb.

Granite County.

Engineer Dorman, of Missoula, superintending building of a dredge at Harvey creek, 12 miles from Bearmouth, for tbe H. H. G. M. Co., says work is progressing. They expect the dredgers to be in operation this spring. The company has extensive placers in Harvey Creek district. The company is driving a tunnel into the mountain. A road has been built from Bearmouth to the placers.

Jefferson County.

The furnaces of the Cataract C. M. Co. plant, on Basin creek, 8 miles from Basin, were blown in last week. Pyritic smelting will be used in treating the low-grade ores of the district.

Missoula County.

H. B. Tilden of Baltimore, Md., has bought the Copper Cliff group of claims, 11 miles northeast of Bonita. They have been worked steadily since 1892. All work has been on development. The ore is said to carry 18% copper and assays $10 in gold. In the Copper Cliff claim a douhle-compartment shaft 200 feet deep has been sunk and an 800-foot tunnel has been driven on the Gilt Edge.

NEVADA.

Esmeralda County.

The mill for the Esmeralda Con. mine at Hawthorne has been completed, and hauling ore was commenced. A carload of fuel oil is on the ground. The stamps hegan dropping this week.

Douglas County.

(Special Correspondence).—F. C. Everett, managing director of the Longfellow M. & M. Co., owning the Longfellow and other mines near Gardnerville, is increasing development work. He is preparing to put in a 4-drill compressor and other machinery, including electric equipment, and also proposes building an aerial tramway 1 mile in length. The company owns placers on the Carson river, which will be worked this season. S. W. Baker is assistant manager.

Gardnerville, March 22.

Nye County.

The MacNamara M. Co. has resumed operations on its mines at Tonopah, with D. J. MacDonald as superintendent. They will drift hoth ways from hottom of the 500-foot shaft.

Storey County.

During last week occurred pay days at the Comstock mines, including tbe Con. Cal. & Va., Ophir, Mexican and Gold Hill mines, the middle mines and Silver Hill. The payroll for the month of Februaary, including Chollar-Potosi croppings and milling plant and Flowery mines, aggregated over $65,000. With resumption of work at the Butters cyanide plant and Best & Belcher mill, the monthly amount dishursed to employes will he increased to over $75,000.

Washoe County.

W. Golding, R. Sommers and F. Norris report striking ore in their Forlorn Hope mine at Olinghouse, showing the ledge 2½ feet wide. They will increase the number of men at work.

White Pine County.

Work is temporarily suspended in the main workings of the Giroux Con. C. Co. at Ely. In the meantime work in the company's Taylor mine is progressing steadily and a new shaft will be sunk. The shaft, which was sunk for prospecting purposes, is too small to meet present requirements, and ventilation is also desired.

NEW MEXICO.

Otero County.

The Jarilla M. & S. Co. has been organized to work mines at Jarilla camp and to carry on a smelting husiness. Among other properties this company has taken over at Jarilla is a five years' hond and lease on twenty claims of the Jarilla M. Co., under which the company contracts to start work of building a 100-ton smelting plant within six months. It is said the company will take over the By Chance group of mines of the Cincinnati G. M. Co. The directors are R. G. Mullen, W. S. and F. E. Boynton, F. R. Jeffrey, D. D. Hunt and J. K. Mullens of Colorado Springs, Colo., and E. E. Sidehottom, A. J. King and E. J. Dedman of Alamogordo.

Sierra County.

The Kanawha G. M. Co. has been incorporated and has bought the Sherman and Lupey mines, east of the Sierra Con. G. M. Co. properties, near Hillsboro. M. H. Straughan and F. F. McConihay of Charleston, Va., and J. and W. Kasser of Hillsboro are officers. The Sherman mine of the group has produced gold and silver, bearing copper ore.

Socorro County.

E. Craig, manager of the Last Cbance group, is preparing to put in macbinery to increase the capacity of the company's 20-stamp mill at Mogollon. It is thought the mill will be in working order again next montb.

OREGON.

Baker County.

A half interest in tbe Sucker Creek placers, of Sucker Creek district, near Sumpter, has been sold to F. Slade for $5000, wbo will overhaul the equipment and resume operations.

Grant County.

The Alamo mill, near Granite, is closed down temporarily to permit installation of a cyanide plant, says J. R. Cassin of Spokane, Wash., secretary and treasurer of the company.

Josephine County.

It is reported that native silver, associated with hismuth, has heen found hy prospectors near Grants Pass.

The Takilma Smelting Co. is preparing to huild a 100-ton smelter on the Darkis place below the Waldo and Queen of Bronze mines, near Waldo, and is expected to he in operation by July 1. The smelter is to treat ores of the Waldo and Takilma mines. A. I. Goodell is manager, and C. L. Tutt of Colorado Springs, Colo., is president.

S. Chase et al., of Portland, are developing the Oro Fino mine of Jump-Off-Joe district, near Graut's Pass. He proposes to put in a cyanide plant this spring.

SOUTH DAKOTA.

Lawrence County.

At Maitland the Garden City group has been sold for $40,000 cash. Other adjacent claims and the Waller millsite were included in the deal. J. B. Le Beau and M. McGillis of Central City, E. E. Peterson of Lead, R. M. Maloney, J. Hogarth and Y. Murk of Deadwood are interested. The claims in this group are the Garden City, Kanoka, Unionville, Hendricks, Beulah and Rochester. The adjoining claims included in the sale are the Dauntless and Big Red.

TEXAS.

The J. M. Guffey Petroleum Co. shipped recently by its steamer to Beverly, Mass., 1,000,000 gallons of refined oil for distribution throughout New England. This oil was refined at the company's refinery at Port Arthur from crude oil produced in the Beaumont (Jefferson county) and Sour Lake (Hardin county) fields.

UTAH.

Beaver County.

Development work on a property adjoining the Cave mine, near Milford, has been resumed hy the Gold Run M. Co., organized hy J. C. Dick, A. K. Tiernan, C. DeMoisey, R. J. Decker and F. C. Dern of Salt Lake City.

Juab County.

Manager J. C. Sullivan of the Raymond mine, near Eureka, is preparing to resume operations at the Raymond. It will require some little time to free the mine of water which has accumulated during the temporary shutdown. The consolidation of the Raymond and Illinois mining companies took place on the 23rd inst. Future development work on this ground will be carried on through the Raymond shaft. The Raymond shaft has been put down to 1500 feet.

In the Grand Central M. Co. ground at Eureka, Superintendent P. Donnelly says for 40 feet he has crosscut the latest development on the 800-foot level northb, without reaching the walls. Smelter returns show average of 40 ounces silver with $30 gold and fractional values in copper, the lead occurring in hunches only. At 260 feet north of crossing on which the Butterfly stope was developed the new crossing was reached.

Piute County.

The Little Marion G. M. Co. has been incorporated to develop a group of seven unpatented mining claims in Mount Baldy mining district, near Marysvale, by E. E. Jenkins, G. T. Henry and B. D. Luce, at Salt Lake City.

Salt Lake County.

The management of the New England G. & C. Co.'s mines at Bingham, which includes the Nast group, above the Boston Con., is equipping the Nast with a jigging plant capable of handling seventy-five tons of ore daily. The building is under cover and the machinery is being set up. The jigs will be operated at the mouth of the main tunnel in Muddy gulch. The product will be sent out over the Copper Belt Railroad from a point near the loading station used by tbe Boston Con. Concentrating is expected to begin by April 15th.

Work on the main tunnel by whicb the Dalton & Lark group of mines at Bingham bas been partially unwatered will be resumed next week, says Superintendent Rodgers. Until tbe draining has been completed, exploratory work and the blocking out of ores will be confined to tbe upper levels. The latest disclosure is in a raise above the 1070-foot level, where 7 feet of sulphide ore containing 4% copper and values in gold and silver has been opened. Meanwhile the management continues to add to its volume of lead ore, of which 150 tons broken down in development is sbipped monthly. D. MacVichie of Salt Lake City is manager of the Bingham Con., by which the Dalton & Lark group is owned.

At the United States R. & R. Co. smelter at Bingham five furnaces are in operation, while the sixth is expected to be blown in by April 15. With the present hattery Superintendent Hazleton says he is reducing 800 tons of ore daily, with the output of bullion containing copper, gold and silver. Meanwhile work on the lead furnaces is progressing steadily.

The Blue Point M. & M. Co. has been incorporated to operate a group of mining claims in Big Cottonwood district, near Alta. A. H. Mereditb, D. Simper, J. W. Guthrie, R. A. Cheek and J. A. Jacobson are officers.

Tbe Fortune group of twenty claims, at Bingham, formerly operated by the Fortune M. Co., has again been merged into a single group, says the Bingham Bulletin. The group as consolidated covers 300 acres. It will be operated by tbe Fortuna M. Co. of Salt Lake City, organized witb J. D. Wood, M. B. Johnson and G. F. Richards, Jr., as officers. While the mine is at present under contract to deliver ore to the Bingham Con. smelter, the company plans to increase development work for larger production and to remodel and operate the concentrating mill on the ground.

Tbe Iowa and April Fool groups (formerly the West Mountain group), consisting of fourteen claims above the Red Wing Extension in Markham gulch, near Bingham, have heen bonded to Cleveland, Ohio, parties and will be developed this summer under management of L. C. Snyder.

Summit County.

The J. I. C. mines, at Park City, have been taken over hy the West Quincy M. Co. which has been organized at Salt Lake City, with G. D. Turner as president.

Tooele County.

The Sacramento mine of Mercur produced ninety-two flasks of quicksilver during the month of Februaary. This was produced from ahout 3000 pounds of ore treated per day. Ahout 140 tons of gold ore is also treated daily.

It is reported that the Western Exploration Co., W. F. Snyder of Salt Lake City manager, proposes huilding a tramway from its Buckhorn mine in Ophir across tbe hills by way of Dry canyon, conveying to its mill ore not only from its own property, but from the properties at Gishorn (Dry canyon), among which latter are the Eureka-Ophir, Pittshurg-Utah (the Mono) and the Dry Canyon Con., the latter operated hy C. J. Garber & Co.

The Whirlwind M. Co., noar Stockton, has six full claims, with considerable work already done, and expects to increase operations this season. The tunnel on the Whirlwind, in the canyon, is in 400 feet, headed in the direction of the Miller mine, whose ore reserves will be drained and opened for transportation. J. Mercer of American Fork is president.

The Chloride Point mine on Lion hill, near Mercur, has resumed shipping ores, under Lessees Clair & Clark.

Wasatch County.

The West Quincy M. Co. of Salt Lake City has heen incorporated to operate a group of mines in Snake Creek mining district, with G. D. B. Turner, W. H. Dodge and R. E. Miller as officers. The company also acquires the holdings of the J. I. C. M. Co., at Park City.

WASHINGTON.

Ferry County.

Work at the Knob Hill mine at Republic is reported progressing. A ledge 7 feet in width has heen opened, assaying $30. The mine is shipping its ore to Nelson, B. C., at rate of three cars per week. ——The Mountain Lion is taking out ore and shipping from one to two cars per day. The mill has closed down and, it is said, will not be started up again until additional machinery is put in.——The Pearl Con. shaft is 60 feet in depth and will connect the surface and the upper tunnel. The lower level is connected with the upper tunnel. When connection has been made, ventilation will be improved and mining will be resumed in the several levels and sbipments made regularly.—— The sbaft on the Golden Eagle mine has reached a depth of 350 feet. It is going down at 2 feet per day. It is expected the Quilp ledge will be cut by May 1st.

Okanogan County.

T. James of Spokane, consulting engineer for tbe Salmon River M. Co., operating on Peacock mountain, south of Conconully, says a 100-foot contract has been finished and another contract of 100 feet given. —— H. Brown and J. B. Holford, who own a group on tbe east side of Whisky bill, have cut a body of sulphide ore in the main tunnel, in 130 feet, from which assays have been had of $20 in gold. —— The Favorite mine has shut down. —— The tunnel at the Six Eagles mine has been cutting stringers of mineral bearing quartz. The tunnel is in 1840 feet. —— The sawmill at the Prize mine is running and sufficient lumher has heen cut to complete the building for the concentrating plant. This is expected to he put in operation next month.

At the Security mine, near Loomis, tbey have opened up a gold bearing shoot of ore in the lower tunnel. The gold is distrihuted through a 5-foot ledge of white quartz. The point of contact is 330 feet from the mouth of the tunnel at depth of 150 feet. This is the third level on which tbis shoot has heen found. The Security joins the Palmer mountain tunnel group on the north, and tho ledge under development was cut in the Palmer mountain tunnel at depth of 1200 feet.

S. E. Barron, manager of the Q. S. mine, near Blue Lake, near Conconully, says the company is arranging to put in a compressor plant and otber machinery.

Stevens County.

The Edna mine (King mine) at Wailtes lake, near Chewelah, proposes putting in a smelter tbis spring, says the Independent. The ore is copper-gold hearing. —— Tbe Copper King mine, near Chewelah, is preparing to make shipments of copper ore. —— Work will he resumed on the Eagle copper mine.

T. H. Walters of Spokane of the Standard Group Marhle Co., says his company will resume work at its quarries near Bosshurg ahout May 1st and that macbinery will he put in. The Standard group consists of 200 acres of land 2 miles north from Bosshurg, on the west bank of the Columbia River, near the Spokane Falls & Northern Railroad. One hundred and sixty acres of the land is patented. The quarries contain several varieties of marble.

Whatcom County.

J. Seigfried and P. Valerius of the Bellingham M. Co., have bought the Index group of seven claims adjoining the company's property and the North American in Slate Creek district, near Bellingham, for $32,000. Ahout $10,000 worth of development work has been done in the drifts and crosscuts, a tramway, etc. The ore is exposed in several places on the main ledge, which is 20 feet wide. Valerius states the Bellingham M. Co. will huild a stamp mill on the group. The accession of tbese claims gives the company a total of twenty-seven claims.

WYOMING.

The State Board of Equalization is taxing tbe coal mines of that State 50 cents per ton of output.

FOREIGN.

AFRICA.

Transvaal.

The Niekerk mine at Klerksdorp reports under date of March 1 at deepest working poiuts the mine is opening out satisfactorily. Machinery will he put up in six weeks. A winze has been sunk below the hottom of level 170 feet east of shaft No. 2, and sample from winze assays 1 oz. 8 dwts. 20 grs. The reef is 4 feet wide. Tbey are preparing upper ground for stoping.

AUSTRALIA.

Western Australia.

Kalgoorlie reports say the Paringa Con. mine has been taken over by Bewick, Moreing & Co. and systematic prospecting has begun.

The management of the Great Boulder mine at Kalgoorlie is preparing to increase its milling capacity. It is said tbe dry process is best adapted to treatment of Boulder ore.

A find of gold is reported made at Norseman, where 200 ounces were taken out in a day. A number of nuggets have heen found.

BRITISH COLUMBIA.

Cariboo.

Work in the deep ground placer mines is reported progressing favorably. The

Cariboo G. F. Co., near Ashcroft, expects to resume after making alterations to the ladder and buckets of the elevator.—— Quartz prospects are being opened up near Keithley.

Cassiar District.

A placer gold strike is reported made on a tributary of the Liard river, below Black, or Devils canyon, 200 miles east and north from Telegraph creek. News of the find was given by a messenger sent out from one of the Hudson Bay Co.'s Liard river posts. Miners and prospectors along the upper reaches of Stickeen and Telegraph creeks are making preparatio s to leave for Liard. The cost of transportation in that section has been reduced through operations of a steamer on the Stickeen river and regular pack trains from Telegraph creek.

East Kootenay District.

The East Kootenay Placer M. Co. has conveyed to the Perry Creek G. D. Co., Ltd., all its mining property on Perry creek, near Fort Steele. The group consists of six leases on Perry creek aggregating 3 miles in length by 400 feet wide. It also includes a steam shovel on lease No. 80 on Perry creek. G. O. Foss and S. Bonnell are officers of the Perry Creek G. D. Co., Ltd.

Rossland District.

Last week at Rossland miners' wages constituting the February payrolls were paid out as follows:

Center Star	$12,400
War Eagle	10,600
Jumbo	3,100
White Bear	3,000
Le Roi	36,000
Le Roi No. 2	13,500
Rossland-Kootenay	2,500
Spitzee	1,600
L X L	700
Grand Total	$83,000

To the foregoing $10,000 may he added, says the Rossland Miner, for amounts disbursed by mines on salary accounts other than the regular payroll, which does not include salaries of managers and other executive officers.

Ottawa reports say an order-in-council has been passed placing petroleum oil on the free list when imported by mining companies for use in the concentration of ores or metal. This is at the request of Rossland mines using the oil process.

Slocan District.

The Neepawa mine at Slocan has been leased to Isaacson Bros. & J. Kinman. ——The Payne mine at Sandon is shipping the magnetized iron, produced by its zinc plant, to Trail smelter. The company is placing more powerful magnets in its zinc separator to produce a finer quality of zinc.

Vancouver Island.

The Richmond Oil Co. has started operations preparing for boring for oil at Steveston. The lumber and machinery are on the ground. R. H. Ferguson of Texas is in charge.

West Kootenay District.

J. A. Darraugh of Camborne, manager of the Tinworkers' G. M. Co. of Elwood, Ind., operating mines of Fish Creek camp, near Camborne, says arrangements are made for resumption of development on the Silver Dollar and Wide West groups. The bond on the Silver Dollar group has been taken up hy the Tinworkers' M. Co. The company also owns the Copper Dollar, but will confine work this season to the Silver Dollar, which group consists of five claims on Mohawk creek.——The Wide West M. Co., with head offices at Lima, Ohio, of which Darraugh is also superintendent, will also increase development. A 511-foot crosscut has been driven showing three galena-bearing veins.

Yale District.

(Special Correspondence).—The Yale M. Co. at Hedley, in Kamloops mining division, is completing construction of a 40-stamp mill, equipped with Frue vanners. It is thought the plant will later be increased to 100 stamps. W. K. Rodgers is superintendent of the mines and mill of the company.

Hedley, March 20.

CANADA.

The Geological Survey Department of the Canadian Government in its official summary of the mineral production of Canada for 1903 shows the total output estimated at $63,226,510, being a decrease of $500,000 from 1902. The value of the metallic products was: Gold, $18,834,490; copper, $5,728,261; nickel, $5,002,204; silver, $1,700,779. Total production of pig iron in Canada in 1903 amounted to 297,885 tons, valued at $3,742,710, of which it is estimated 42,052 tons, valued at $707,838, should he attributed to Canadian ore and 255,833 tons, valued at $3,034,877, to ore imported.

Alberta.

The International Coal & Coke Co., A. C. Flumerfelt of Victoria, B. C., president, in its annual report of operations at the coal mines at Coleman, 50 miles east of Fernie, B. C., shows work progressing satisfactorily. They are doing only development work, but are taking out 150 tons of coal a day. They expect to mine 2000 tons of coal a day, and are getting in machinery to handle that amount. It will include a complete electrical plant in the mine and tipple. Compressed air will be used for haulage. The dry walls and cribbing for the first battery of 104 coke ovens are completed, and the brick work will be put in as soon as weather permits. It is intended to build 300 more ovens next summer. The ovens have a capacity of from a ton to a ton and a half of coke. The grading of the sidings at the mine and the track to the ovens is completed.

Cape Breton Island.

The discovery is reported of nickeliferous copper ore on Cape Breton Island. The ore body is said to be 270 feet wide and carries gold and silver, besides high values in copper.

Nova Scotia.

Referring to the recent strike of gold, the Agent General for Nova Scotia says bodies of high-grade ore have been struck at depth of 950 feet, in the Caribou district, Halifax county, and that similar reports come from Isaac's Harbor.

Ontario.

United States Consul Borgholz, at Three Rivers, writes that asbestos deposits are reported to have been found in Addington county.

Yukon Territory.

Two Klondike quartz mines are shipping ore, say Dawson reports. Ore from the Klondike Chief mine, opposite the mouth of the Klondike river, is being crushed at the Matheson stamp mill. W. Foster, part owner, says the mine has 50,000 tons of free gold ore in sight. The Violet group has also started shipping ore. The company is being reorganized as the Violet Mine, Ltd. A 10-stamp mill will he built this summer. Six men this winter have sunk a vertical shaft 150 feet, at which depth the vein was crosscut, showing a width of 17 feet. The ledge has a talc seam on both hanging and foot walls.

INDO-CHINA.

The report of British Consul Little at Pakhoi shows, in comparing the Annamite workmen with the Indian, the manager of one of the mills describes the former as more tractable and enduring, and equally skillful, hut complains of difficulty of retaining them for any length of time. Taking everything into account, he considers native labor little or no cheaper than European. The present output of the Nongson coal mines is at rate of 100 tons per day. At the Hongay mines 2500 men are employed, and the surface has been removed to depth of 25 meters, it being an open-cut working. The length of the railway from the mine to the port of shipment is 11 kilometers (about 7 miles). An iron mine is being worked in the Province of Thainguyen, one of iron and manganese in Phu-lien, and one of antimony in Quangyen. Forty-nine mining claims have been registered, viz., twelve for coal; twenty for gold, mostly in Hoabinh Province; four for copper, in Vanbu, Tha nguyen and Yenhay; two for iron in Quangyen, and seven for tin and other metals. Deposits of nickel have been found in Province of Tuyenquang, and of coal at Muong Pan, in the Upper Laos. The discovery of the latter was made by the coal having been set on fire hy the natives in clearing the hills of brush. The hill has now been burning for some months.

MEXICO.

Mexico City reports say statistics just compiled show that 1,000,000 people are dependent on the mines of Mexico. There are 28,825 people employed under ground and the number employed above ground brings the total to 200,000. In addition to those actually engaged in mining, there are many indirectly dependent upon it, such as wood cutters, drivers and cart men. The families of these employes fill out the total of dependents.

Chihuahua.

S. Madero, treasurer of the Cia. Metalurgica de Torreon, owning the smelter at Torreon, says his company is increasing development work on the Sau Diego mine at Santa Barhara and the question of building a concentrating plant there is heing considered. Ore is being oponed up, hut it is low grade and will require concentration. The group is crossed by the Mexican Central's branch road to Santa Barhara. J. W. Pender is manager.

G. G. Gillett has hought the Quehradillas mine at Minas Nuevas for the Pan-American M. & S. Co. of New York for $700,000 gold. The mine has heen operated by Stallforth & Co. for four years past. It is producing eighty tons of high-grade ore daily. Pumps and other machinery are being put in, and it is said production will be increased 100 tons daily.

J. W. Pender of Santa Barbara has bought the W. G. Gibson half interest in the Socorro M. Co., owning the Socorro mine, near Ocampo. This mine is a gold property which has been idle for some time, due to differences between the owners. It is equipped with a mill, buildings, etc.

F. A. Hazzard of Whittier, Los Angeles county, Cal., is increasing development work on the Minerva mine at Santa Eulalia. A shaft is being sunk.

Coahuila.

The American M. & Dev. Co. proposes building a smelter at Torreon and an electric power plant for its mines at Velardena.

The American-Moxico M. & D. Co. has bought 700 acres of ground at Torreon, where it will erect a 1000-ton smelter. This includes part of the mountains where they will obtain the lime rock necessary for flux. They have heen buying a number of lead mines in that section.

Guerrero.

The Pacific Steel Co. of New York is reported having an option on the iron deposits on the Balsas river, in Guerrero.

Hidalgo.

El Almaden and La Providencia mines, bonded by J. M. Erskine of Mexico City, are being developed. They adjoin and consist of 100 pertenencias (247 acres). The ore is said to average 2.3% in quicksilver at bottom of shaft, which is 250 feet deep. A gold and silver vein within 30 feet of the surface shows width of 12 inches and assays 1900 grams silver and 24 grams gold.

Jalisco.

The Santa Lucia mine, near Mascota, is heing put in shape for extraction of ore. It is owned by Mascota men.——Dewey & Lockhart of Guadalajara, part owners in the Soledad mine in Ameca district, will build a concentrating mill for testing ores of the mine.

The Lupita M. Co., P. Fitzgeraid manager, is preparing to enlarge the reduction plant. Hoisting machinery is being put up. The mine is near Mascota in Hurtado district.

The Dwight Furness Co., S. e C., is sinking a double-compartment shaft and driving a tunnel on the Rosario group near Mascota, in Hurtado district. It is understood this company will also start work on the Frontera group under superintendence of W. Oliver.

The United Mexican M. & M. Co., F. W. Page manager, is preparing to put in a 10-stamp mill, sawmill, concentrating tables, pans and settlers, reverberatory furnace and chlorination plant to he erected on the Tatuani river in Navidad district, near Mascota.

The Tajo M. Co., at Rosario, will put in hydraulic machinery to work the hed of the Rosario river for gold. The tailings of the mill have been going into the river for 200 years.

Nuevo Leon.

The Norias de Bajan M. Co. is planning building a smelter at Monterey, and has stopped shipping ore to smelter No. 3 in that city. The company's mines are said to have good fluxing ores.

Sonora.

L. Killeen of Phœnix, Ariz., assistant manager of the Beleno M. Co., states that operations in those properties will be resumed in June. Three shafts are sinking, 500 feet apart, to cut the ore body pitching out of the adjoining Copete ground, which, it is expected, will be struck at depth of 550 feet. The main working shaft—double compartment—is down 327 feet. It is intended to connect the three with a drift and to carry the main shaft to 600 feet or more. In going down several stringers of copper ore carrying gold values have been cut.——Operations have heen resumed in the Copete mine, under management of C. F. Spraker of Nogales, Ariz. He is working upon the 500-foot level.

Zacatecas.

The American S. & R. Co., which has an option on the Gran Cuadra Prodigio y Anexas mine, near Zacatecas, is reported to have invested $44,849 in machinery and has sunk 40 meters upon the principal shaft of the Rondanera. This shaft is down 300 meters.

The Transvaal C. Co. reports operations progressing at the company's group in Moctozuma district, 16 miles west of Cumpas. The group consists of four copper mines and a group of gold claims. The company has 350 men employed and 8000 feet of underground work. Air compressor plants, steam hoists and twelve permanent buildings are among the improvements.

NEW ZEALAND.

The New Zealand gold returns for month of February are reported amounting to 52,011 ounces, valued at £201,066, as compared with 16,238 ounces, valued at £58,051, for February, 1903.

Personal.

M. K. Rodgers is superintendent of the Yale M. Co. at Hedley, B. C.

T. P. Rigney of Salt Lake City, Utah, is in New Mexico examining mines.

J. Carmen is superintendent of the Zenith mine and mill, near Joplin, Mo.

C. H. McCaffrey is superintendent of the Wheeler mine, near Plymouth, Cal.

D. J. MacDonald is superintendent of the MacNamara M. Co. at Tonopah, Nev.

L. L. Miller of Chicago, Ill., is in Denver, Colo., looking after mining interests.

H. C. Baisch, a mining operator of Telluride, Colo., is in San Francisco, Cal.

L. C. Snyder is manager of the Iowa and April Fool groups, near Bingham, Utah.

G. W. Boggs of Tacoma, Wash., is manager of the Morning mine near Sumpter, Or.

T. J. Bernard, a mining engineer of Sydney, Now South Wales, is in Rossland, B. C.

W. Kemp is manager of the Copper Belle mines, in the Dragoon mountains, near Tombstone, Ariz.

President Smith of the Old Dominion copper mines at Globe, Ariz., is at the mines from Boston, Mass.

D. MacVichie, manager of the Bingham Con. C. Co., is in Boston, Mass., from Salt Lako City, Utah.

L. A. Nares of Laton, Cal., interosted in northern California mines, is in San Francisco, Cal., on business.

A. I. Goodell is manager of the Takilma S. Co., operating copper mines near Waldo, Josephine county, Or.

T. S. Costello is manager of the Denver branch of the Diamond Rubber Co., vice W. W. Whiting, resigned.

C. M. Belshaw, president of the California State Miners' Association, is in San Francisco, Cal., from Antioch, Cal.

H. Joseph of Salt Lake City, Utah, has retired as manager of La Reine mines, near Eureka, Tintic district, Utah.

Geo. F. Beardsley has returned to San Francisco, Cal., from an examination of mining property near Keswick, Cal.

W. L. Cole, superintendent of the Mountain C. Co. of Keswick, Shasta county, Cal., is in San Francisco, Cal.

F. E. Shepard, president of the Denver Engineering Works Co., Denver, Colo., has returned from Salt Lake City, Utah.

W. P. Hammon, interested in dredging operations at Oroville, Cal., is in San Francisco, Cal., from a business trip to the East.

A. G. Wehe, formerly manager of the Nighthawk M. Co.'s mine at Nighthawk, Wash., has opened an assay office at Loomis, Wash.

R. J. Cory, manager of the Denver, Colo., branch of the Allis-Chalmers Co., has returnod there from a trip to Salt Lake City, Utah.

G. H. Masters of Berkeley, Cal., has gone to Gardnerville, Nev., as electrical engineer for the Longfellow M. & M. Co., near Gardnerville.

Manager R. H. Channing of the Utah Con. C. Co. at Bingham, Utah, returned to Salt Lake City, Utah, last week from California.

F. H. Bostwick, of the Hendrie & Bolthoff Manufacturing & Supply Co., Denver, Colo., has returned there from a trip through Arizona.

H. McGarry of Colorado Springs, Colo., is manager of the Golden Cycle M. Co., operating the Golden Cycle mine at Independence, Teller county, Colo.

J. E. Hewston, formerly superintendent of the Norwegian mine in Tuolumne Co., Cal., is superintendent of the McKinley mine, near Fort Jones, Siskiyou Co., Cal.

S. W. Baker, assistant manager of the Longfellow M. & M. Co., near Gardnerville, Nev., has returned to Gardnerville from a business trip to San Francisco, Cal.

H. C. Holthoff, general manager of the Power & Machinery Co., Cudahy, Wis., has been in Denver, Colo., and Salt Lake City, Utah, on business connected with his company.

G. D. B. Turner of Salt Lake City, Utah, president of the West Quincy M.

Co., owning the J. I. C. mine of Park City, Utah, bas gone to Glasgow, Scotland, on company business.

S. W. Traylor, Eastern manager of the Colorado Iron Works, Denver, Colo., is on a short visit to the firm's headquarters. He expects to return to New York by April 1.

T. H. Oxnam, manager of the Palmarejo & Mexican G. F., Ltd., returned to Los Angeles, Cal., last week from the company's mines near Chinipas, Chihuahua, Mexico.

Epes Randolph of Tucson, Ariz., has been elected president of the G. V. G. & N. Ry., to succeed William Garland, who has been president of tbe road since its completion in 1894.

H. D. Conant, till recently assistant superintendent of the Lake Superior Smelting works at Dollar Bay and Hancock, Mich., bas been appointed superintendent, vice J. J. Case, resigned.

W. Zeigler has resigned as superintendent of the Granite Mountain M. Co. at Granite, Mont., and bas gone to Bingham, Utab, as general superintendent of tbe mines of the Ohio C. Co.

The directors of the Allis-Chalmers Co. have elected B. H. Warren president of the company in place of Charles Allis, who resigns on account of tbe illness of his wife, wbich necessitates a long trip abroad.

L. E. Hill has resigned as secretary and manager of the Golden Cycle M. Co. at Cripple Creek, Colo., to devote his time to leases which he holds on several Cripple Creek properties, among tbem the Theresa.

T. James of Spokane, Wash., has resigned as consulting engineer for the Salmon River M. Co.'s mines, near Conconully, Wash., and will devote his time to development of properties at Pony, Mont., and in Arizona.

Philetus W. Gates and Henry W. Hoyt, respectively general superintendent and second vice-president of Allis-Chalmers Co., are about to retire from active participation in tbe management of that company. Mr. Gates was president and Mr. Hoyt secretary and general manager of Gates Iron Works for fifteen years prior to the incorporation of Allis-Chalmers Co. in 1901. They have been prominently connected with tbe manufacturing interests of Chicago and have taken an active part in all of tbe manufacturers' associations. Tbe late P. W. Gates (father of Philetus W. Gates) was the pioneer manufacturer of Cbicago and the region west of the Allegbenies, having established his business in 1842. From 1861 to 1871 the Eagle Works Mfg. Co., of which he was president, employed about 1000 men, and in those days was a noteworthy industry. In 1871 the Eagle Works Mfg. Co. went out of existence and from it were organized Gates Iron Works and Fraser & Chalmers, each taking a portion of the business. Both of these companies in turn were taken over by Allis-Chalmers Co. in 1901. Messrs. Hoyt and Cates, after a well-earned vacation spent in traveling, will re-engage in business in Chicago.

Trade Treatises.

A model catalogue in every way is the 6x9-inch (standard size) sent by the Stephens-Adamson Mfg. Co., Aurora, Ill., the 208 pages being a compendium of information concerning the elevating, conveying and power-transmitting machinery that they furnish. It will be sent to any address on request.

From the Westinghouse Electric & Manufacturing Co., Pittsburg, Pa., is received Catalogue No. 1077, "Type L Motors, Direct Current, Series Wound," and Catalogue No. 1078, "Westinghouse No. 91 Single Phase Railway Motor and Car Equipment." Large editions of these circulars have been printed and copies can be had upon request.

The Foote Mineral Co., 1317 Arch St., Philadelphia, Pa., is now preparing for tbe press a catalogue which is said to be one of the most complete and extensive of its kind in the entire field. The work is 96 pages, copiously illustrated and treats exbaustively of ore and mineral collections for prospectors and mining school use. A postal of inquiry will bring a copy by return mail.

Bound in red and bound to be read is the brochure on "Boot Facts" from H. J. Putman & Co., Minneapolis, Minn., which tells in a plain way about a boot they make for engineers, prospectors, miners, surveyors and any one who wants foot gear that is comfortable, durable and waterproof. That they make a good boot for mining men is shown by the testimonials tbey publish from all over the world. They will be pleased to send this book or their regular catalogue to interested parties anywbere. Address H. J. Putman & Co., 26 Hennepin Ave., Minneapolis, Minn., U. S. A.

Commercial Paragraphs.

Netland & Bolger have opened a civil and mining engineer's office at 303 California street, San Francisco, Cal.

Fairbanks, Morse & Co. of Cbicago have engaged M. Greenwood, formerly Pittsburg manager for the International Steam Pump Co., to look after tbeir steam pump business in the Pittsburg territory.

H. C. Holthoff of the Power & Mining Machinery Co., has a contract for a plant for the Takilma Smelting Co. at Takilma, Or., 45 miles from Grants Pass and 55 miles from Crescent City, Cal. Tbe smelter is to handle the gold and copper ores of tbe Waldo S. & R. Co. Albert I. Goodell is to be general manager.

The Pacific Steel Co. incorporated this week at San Diego, Cal. The company is capitalized at $100,000,000. Its objects are stated to be the construction of warships, steamsbips, locomotives and cars and to make armor plate, to deal in lands containing iron and copper deposits and operate mines for smelting purposes and to construct furnaces and mills. The company say they will construct a steel plant to cost $30,000,000.

The Sullivan Machinery Co., through their Denver, Colo., branch, have recently sold one 12x30 Corliss geared, double-drum hoisting plant and one 16x16x10x16 compressor to tbe Santa Eulalia Exploration Co., Cbihuahua, Mexico; one 17x42 first-motion, single-drum Corliss hoist to the Calumet & Arizona Development Co., Bisbee, Ariz.; one 17x42 double-drum, first-motion Corliss boist to the Calumet & Pittsburg M. Co., Bisbee, Ariz.: and three 20x22x14x24 compressors to James Degnan & Co., Wilburton, I. T.

The Sullivan Machinery Co., Cbicago, reports that owing to tbe growth of its business it is making several cbanges in tbe addresses of its different offices tbis spring, to secure larger quarters and increased facilities. The New York office, A. E. Blackwood manager, is now located at 42 Broadway, rooms 1427-28, instead of the Empire Building, 71 Broadway, where it has been located up to tbis time. On April 1st the Pittsburg office, Geo. W. Favor manager, will move from the Schmidt Building, 339 Fiftb avenue, to the Farmers' Bank Building, where it will occupy rooms 1112-13. On or about April 15th the general offices located heretofore at 135 Adams street, Chicago, will move into the newly completed Railway Exchange Building at the corner of Jackson boulevard and Michigan avenue, where they will occupy rooms 1502-14 inclusive.

The Pelton Water Wheel Co. report that there are now over 11,000 Pelton wbeels in operation in various parts of the world, in connection with electric transmission, mining, manufacturing and other industries, aggregating in excess of 1,000,000 H. P., viz.:

In the United States—	Wheels.	Aggregate H. P.
California, Oregon and Nevada	7,647	708,370
Washington, Idaho and Alaska	623	58,225
Utah, Colorado and Montana	176	24,970
Hawaii, New Mexico and Arizona	208	13,800
Middle West and Atlantic States	146	5,670
In Foreign Countries—		
Mexico and Central America	636	152,905
Various South American States	371	24,660
Australia, Japan and India	484	40,250
East and West India Islands	243	30,250
British Columbia and Nova Scotia	52	10,500
England and South Africa	77	12,220
Germany, France, Italy and Spain	341	4,820
Norway, Sweden and Denmark	36	2,800
Totals	11,040	1,089,440

The company further states: "In excess of 80% of efficiency is reported by the Gold Stream plant of the British Columbia Electric Railway at Victoria, B. C. So well satisfied is tbis company that they have given the Pelton Co. another contract which is to increase tbe output of the Gold Stream plant. This additional installation will consist of a water wheel unit for direct connection to a 1000 kilowatt Canadian-Westingbouse generator. This unit will consist of two wheels fitted with the latest type of Pelton buckets and needle nozzles with pilot control, and are to operate under an effective head of 600 feet. The wheels will be mounted one on each end of the main shaft, which will be carried on ring, oiling, ball and socket Pelton generator type bearings, and the wheels will be completely enclosed in sheet steel housings, mounted on heavy bed plates, made also to carry the armature of the generator, thus making a complete iron-mounted integral unit with the Westinghouse engine type generator. This unit will give considerable reserve capacity to this plant, which bas been operating most successfully for a number of years past."

Latest Market Reports.

San Francisco, Marcb 25, 1904.

METALS.

Silver.—Per oz., Troy: London, 25⅞d (standard ounce, 925 fine); New York, bar silver, 55½c, refined (1000 fine); San Francisco, 55⅛c; Mexican dollars, 45½@46½c San Francisco, 44⅛c New York.

Copper. — New York: Standard, $12.50; Lake, 1 to 3 casks, $13.00; Electrolytic, 1 to 3 casks, $12.87½; Casting, 1 to 3 casks, $12.75; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £56 15s spot per ton.

It is stated tbat since Jan. 1, 1904, the monthly consumption of copper in the United States has been 16,000 to 17,000 tons, and exports have reached about 57,000 tons per month. As tbe production of American mines bas not exceeded 33,000 tons per month during this period it is evident that the stocks on hand at the beginning of tbe year must bave been drawn upon beavily to supply the deficiency, still the price shows no advance, and, in fact, it is said that large amounts of the metal have been sold in Europe at a fraction under tbe market quotations.

Following are the figures of German consumption of foreign copper for the month of January, 1904, compared witb tbe same period of 1903-1902:

	1904. Tons.	1903. Tons.	1902. Tons.
Imports	9,391	6,829	9,705
Exports	676	795	1,482
Consumption	8,715	6,034	8,223

Lead. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.85. London: £12 5s ℔ long ton.

Spelter.—New York, $5.15; St. Louis, $5.00; London, £21 17s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

Tin.—New York, pig, $28.85@29.12½; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 31c; less, 32c; bar tin, ℔ lb., 32¼@35c. London, £130 2s 6d spot.

Platinum. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75@82c ℔ gram.

Quicksilver. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ℔ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

Babbitt Metal.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

Solder. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

Zinc.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

Nickel.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

Aluminum.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

STRUCTURAL MATERIALS.

Iron.—Pittsburg, Bessemer pig, $13.85@14.35; gray forge, $12.60; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

Steel. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00@23.00; San Francisco, bar, 7c to 12c ℔ lb.

Fuse. —Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

Candles.—Granite 6s, 16 oz., 40s., 11½c ℔ set; 14 oz., 40s., 10c.

Chemicals. — Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.20@1.40 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potasb, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, French, 3½@3¾c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; cbloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

Bone Ash.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

Coal. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.00; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Antbracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

Oils.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 47c; cs., 52c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtba or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

White Lead.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

Red Lead.—500 lbs. and over at one purchase, ℔ lb., 6½c; less than 500 lbs., 7c.

Litharge.—Pure, in 25-lb. bags, 8@9c ℔ lb.

Borax.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

Manganese.—Pure, ℔ lb., 60c.

Sodium.—Metal, ℔ lb., $1.00.

Bismuth.—Subnitrate, ℔ lb., $2.00.

Mercury.—Bichloride, ℔ lb., 77c.

Molybdenum.—$2.00 ℔ lb.

Chromium.—90% and over, ℔ lb., $1.00.

Phosphorus.—American, ℔ lb., 75c.

Silver.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

Aluminum.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

Uranium.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Utility of the Canvas Plant.

The canvas slimes plant is a distinctive feature of gold milling practice in California. It was first introduced in that State in 1884, and was known at that time as the Morris table, from the inventor. Prior to this, however, the use of various fabrics for concentrating gold from fine sand and from crushed ore, tinstone from its gangue, and other heavy substances from the lighter material with which it was associated, had been employed. As early as 1879 the sulphurets from the Homestake mills in South Dakota were concentrated on strips of brussels carpet, and in California mills heavy blankets and gunny sacks had been used for the same purpose. Long before this the Brazilian miner concentrated his gold on bullock skins, and even this was nothing new, as the ancient miners of the old world did the same thing in the same way centuries before. The California canvas plant, as now operated, is the refined result of the crude earlier practice, and it has now been carried to such a nicety that, under competent direction, an extremely close saving of values is obtainable from gold mill tailings. Elsewhere herein is an article on this subject, in which the author describes his practice at the Gold Bank mine in Butte county, Cal. The methods there employed differ materially from those employed at similar plants elsewhere, and are worth studying. Although he states he had an opportunity to experiment with the tailings from the concentrating mill of the Bunker Hill & Sullivan mine, at Wardner, Idaho, and states that his results were satisfactory, the management there has discarded the slimes plant. The discontinuance of the use of canvas tables at this property, despite the good results previously reported as having been obtained, may represent the difference between the men in charge of the plant at two periods of time. One was a careful, painstaking experimenter, the other a workman whose duty was to look after the canvas plant, which he did, probably to the best of his ability; but the personal equation is a large one when comparing results obtained on canvas plants. The difference is much greater, usually, than would be found in the work of two men in charge of concentrating machines of almost any design. These, once properly adjusted, will do about the same kind of work continuously unless some radical change takes place in the ore or in the volume of material or water coming onto the machine. This change will quickly manifest itself on the upper end of the belt or the lower end of the table, and would promptly attract attention. In a canvas plant any change is not so quickly noticeable. The pulp flows continuously over the tables for hours, and any change occurring is not detected until the pulp is shut off and clear water turned on, and possibly none would be noticed then in most instances, but a change is detected by assaying concentrates and tailings.

The place where the slimes plant appears to find its particular field of usefulness, and to operate to the best advantage, is at those mills where the stamp duty is high; where the relative size of the particles coming from the mill have a very wide range—from slimes to grains as large as will pass a 900-mesh screen—and where the pulp goes direct to the concentrating machines without hydraulic classifying being practiced. The natural result follows. It is found that all of both coarse and extremely fine particles of sulphide cannot be caught on the machines, and the canvas plant gets the tailings with their values lost from the machines. Without doubt, if hydraulic classifying were introduced, and the pulp properly classified before being sent to the machines, the canvas plant would receive tailings of far less value, and, in some instances at least, be made to operate at a profit. The class of work that well made mechanical concentrating machines can perform is well illustrated at several large canvas plants in California, where the sulphurets concentrated on the canvas tables are recleaned on machines of special design, running at a speed and stroke suited to the class of material they are required to handle. The result is satisfactory. However, the canvas plant is comparatively inexpensive, and so long as hydraulic classifying by experienced men is neglected in the average gold mill, there will remain a wide field of usefulness for the canvas plant as a means of concentration.

Title to Unpatented Claims.

There seems to be an impression among many that unpateuted mining locatious are not subject to taxation, the idea seeming to be that as the Goverument has not passed title by patent to the locator the title rests in the Governmeut. It is not easy to define the nature of the estate acquired and held by the possession of a valid mining location, but from the early history of mining the title acquired by a miner to his claim by location was absolute so long as he complied with the statutory provisions. The claim was recoguized as real property, was liable to sale on execution, aud was subject to taxation. With passing years this idea has not changed materially, nor at all. A mining location properly made, and upon which all the requirements of the law have been complied with, is property in the strictest sense of the term, as much so as a patented claim. As a matter of course, if the claim holder ceases to comply with the law regarding claims so located, his rights in the estate cease and the claim reverts to the public domain, and is then subject to relocation by any person, a citizeu of the United States. The miner's title to his unpatented claim is founded upon the law of possession. In the early days of mining there was no other way of maintaining possession of mining claims than by complying with certain local laws and requirements. These local laws, rules and customs came, iu time, to be the foundation of the mining law as it exists at present. In establishing rights under the mining law the fact was recognized that no person could enter upon a claim legally held by another, on the plea that he had no title, as the title was still vested in the Government. The fact of possession was considered sufficient evidence of title. To be in possession does not involve the necessity of an actual residence upon the mining claim. If a mining claim be legally located upon the public domain, and all the acts performed in connection with such location as are required by the Federal Statutes, State and local laws, the locator is said to be in possession, and he has a legal title to the claim to the exclusion of every one else—even the Government—aud he may maiutain this right so long as he complies with the requirements of the law.

Selection of a Process.

In new mining camps the selection of a process to treat the ores, which may differ in character from those with which the operators have been familiar elsewhere, is an important matter. There are numerous recognized processes, usually bearing the name of the inventor, or of the district where first introduced, or the process may be knowu by a name suggested by the materials largely employed in its application — the chlorinatiou process, lixiviation process, cyanide process, Patio process, Washoe process, etc. Each of these processes have usually many variations, and sometimes they are made up of a combination of processes such as amalgamation, concentration and cyaniding. The various processes which have proven successful are those which have been evolved in some particular district after a long series of experiments, often accompanied by repeated failure in the earlier attempts. Not infrequently the process which eventually solves the difficult metallurgical problem is the result of fortuitous discovery, though more often it comes from studied trial of well-known chemical reactions. In the early history of the Black Hills of South Dakota the telluride ores were found most difficult to treat. Numerous processes were tried, and failure after failnre, both mechanical and chemical, resulted, but finally three processes were found each of which treats those ores, saving a high percentage at nominal cost. These are the chlorination process, the cyanide process aud pyritic smelting. The first two are independent of other ores than the telluride ores themselves. The other depends upon being able to obtain the necessary fluxes and pyritic material at low cost. All students of metallurgy are familiar with the Washoe process, which was worked out at such great cost, aud after repeated failnres, on the Comstock, but while well adapted to conditions on the Comstock, the Washoe process is not adapted to the telluride ores of South Dakota or to those of Colorado. At Tonopah, Nevada, the mill men are searching diligently for a suitable process to work those ores, but as yet only partial success has rewarded these efforts. The Washoe process will not accomplish this without auxiliary apparatus. It is evident that the sulphide ores of that camp must be crushed dry, roasted, aud then treated. Possibly after roasting they would be found amenable to the Washoe process. Roasting, simple amalgamatiou and cyaniding have been suggested. Also a combination of roasting, cyanidation and subsequent lixiviation of the silver is another idea as yet untried on a commercial basis. The ores are of good grade, and when a railroad makes Tonopah easily accessible the result will be as in the Black Hills—new brains, new money and experience will quickly solve the problem of recovering the values from those ores.

In the selection of a process, the investigator must be free from prejudice, and not wedded to some particular theory or invention. The broad-minded liberal experimenter will more quickly reach a satisfactory solution of such a problem than he who plods wearily along the same old trail, endeavoring to adapt the ore to his pet process or theory. Processes must be adapted to ores, for ores cannot be adapted to a process unsuited to it without preliminary expense which may render the operation a commercial failure.

Labor on the Rand.

After months of effort on the part of mine managers and others with influence on the Rand iu South Africa to secure permission to import Chinese laborers to work in the mines there, the settlement of the matter seems almost as far distant as in the beginning of the agitation. It has now partaken largely of a political nature, in which the positive necessity for cheap labor to continue operations on the Rand seems to be lost sight of. The opposition from Australia is largely due to the labor element in politics there, though in what respect the affairs of the Rand concern Australia is difficult to understand. The mines of the Rand were largely profitable in their early history, though worked with native Kaffir labor, aud, without doubt, they would have proven profitable also had they been worked exclusively with skilled white labor; but now, the great depth at which most of the companies are working, and the still greater depth at which most new concerns must operate, has placed a different aspect upon the situation. The mines, to be profitable at all, must have cheap labor. As it seems impossible to obtain this among the natives of the surrounding States, the mine managers have turned to China as a country able to supply this need. Even the skilled workmen employed on the Rand have signed the petitions asking that the Chinese be permitted to come into South Africa, realizing that, unless relief be obtained from some direction, the mines must close down, throwing thousands out of employmeut and hopelessly tying up millions of iuvested capital.

Comparative Cost of Shaft Sinking.

In shaft sinking cost is always an interesting and important feature. Elsewhere herein is an interesting description of the rapid sinking of a shaft in Rhodesia, S. A., on the Kleinfontein mine. In this article is giveu in tabulated form the cost of sinking. One of the items to attract atteution is the statement that 1404 cubic feet of timber were employed in the work, costing about $365. This would make a total of about 16,800 feet, board measure, the usual method of measuring timbers. The dimensions of the timber used are not given, but presuming that 8x8-inch timbers were employed, this quantity would scarcely timber more than 80 feet of an ordinary vertical shaft, without lagging, ladders, guides, etc., it is evidcnt that either very little timber was placed in this shaft, if vertical, which is improbable, or that it is an incline, in which only foot wall plates were laid. The difference in the expense of timbering a vertical shaft with full sets, aud merely placing sills in an incline, is a large item, amouuting in this case to not less thau $4 per foot for timber alone, not figuring laggiug, etc., besides the additional expeuse of framing and placing, which would probably have increased the expense to over $14 per foot, bringing the total cost of the shaft to about $80 per foot, and possibly somewhat more. This simply emphasizes the necessity for explicit statements as to the conditions under which costs are made in mining, when these figures are to be used for the purpose of comparison with costs elsewhere. The work done in the shaft in Rhodesia is evidence of good work performed, in which white labor was largely employed and rapid headway made, the whole being a compliment to the management, but a study of the conditions and costs shows it not to have been much cheaper than the shafts sunk elsewhere under somewhat similar circumstances and conditions, though the speed with which the shaft was sunk has seldom if ever been excelled in hard rock mining, beiug an average of 5.67 feet per day for a continuous period of five months.

THE introduction of the metric system in Great Britain is now under consideration in the House of Lords, the matter being in the hands of the committee on weights and measures. It would be a great improvement over the existing systems. The principal objection to the introduction of the metric system in England and the United States comes from mechanical engineers and manufacturers, who claim that its adoption would meau the necessity of an entirely new system of gauges, machines, etc., involving great expense. This is an important consideration, of course, but it would require only a few years in America to adapt ourselves to a system, the advantages of which may be compared to the superiority of the decimal monetary system of the United States over the cumbersome English coinage of pounds, shillings and pence.

THE statements of most of the larger companies operating in Western Australia show that a considerable amount of money is constantly expended in new development work. For instance, the report of the Great Boulder, at Kalgoorlie, for December last shows an expenditure of about $1.45 on dead work or development for each ton of ore extracted. This is a matter too often neglected in mines, the management of which is above reproach. Few mines can endure for long periods without carrying forward development work contemporaneously with the extraction of the known ore bodies. It is a necessary feature of good mining to carry on exploration while exhausting the reserves.

CONCENTRATES.

THE mineral sample from J. S. J., Los Angeles, Cal., is semi-opal and of no value.

THERE are few if any mills in California or on the Pacific coast crushing through an 80-mesh screen, but where such extremely fine crushing is desirable it is usually done in ball mills.

PLACER and lodo claims not patented, as well as those that are patented, are subject to taxation, and also subject to sale on execution by the proper officer in default of payment of such taxes.

SO FAR AS KNOWN, ore is not as yet reduced wholly by electricity, although electricity is employed to a considerable extent in metallurgical processes. It is employed chiefly in depositing metals from solutions.

QUICKSILVER squeezed through canvas or drilling from amalgam always contains a small amount of fine gold which passes through the mesh of the fabric. This fact is not detrimental to the mercury, as it aids in amalgamation, the presence of gold in the "silver" being desirable.

THE mineral from Indian Gulch, Cal., is pyrophillite, a mineral of the talc species, though pyrophillite is an aluminous silicate, and talc is a basic metasilicate of magnesium. The specimen has no value other than as a cabinet specimen. The purple color is due to iron oxide. The normal color is usually a pale whitish green, or clear white.

GEOLOGISTS are not agreed as to the origin of Yosemite valley, Cal. Some believe it to be of glacial origin, others think it due to the dropping of a great block of granite between two walls. Still others think that both of these causes are in a measure responsible for the formation of the valley, but the topography has since been changed somewhat by erosion.

THE friction incident to cars rounding a curve is due chiefly to the fact that the flanges of the wheels "bind" on the inner surface of the rails. This friction is largely reduced by employing car axles made in two sections, the ends meeting underneath the car midway between the sides. It may also be further reduced by lubricating the curved rails with crude petroleum.

GOLD, silver and wolframite are associated in ore from Yellow Creek, 2 miles south of Lead, S. D., and in other localities of that vicinity. This is an unusual combination. Several years since a large quantity of wolframite (a tungstate of iron and manganese) was shipped from a mine at Lead. Wolframite is often found associated with tin ore, but heretofore, rarely known with gold.

LEAD was first mined in southwest Missouri and at Mine La Motte, but later zinc appeared in quantity as the mines went deeper. The zinc industry in time eclipsed that of lead production, and now the output of lead is considered a by-product of mining operations as compared with zinc. In recent years numerous large bodies of zinc ore have been discovered near the surface.

THE value of a grain of placer gold depends upon the fineness of the gold. By fineness is meant the number of parts of pure gold contained in 1000 parts. A grain of pure gold is worth $0.0375. Placer gold is paid for according to the value of the gold it contains, nothing being paid for the silver content unless there be a large amount of silver present, with correspondingly less gold.

IT is believed a shaft can be sunk to a depth of 8000 feet, as far as mechanical difficulties to be overcome are concerned, but the heat developed at that depth may prove an insurmountable obstacle. It is not believed that water will be encountered in great amount below 4000 feet, and the heat which may be anticipated at greater depth will vary to a great extent in various regions.

IN chemistry the term atom is frequently used. An atom is the smallest possible amount of matter into which an element can be divided. It is the unit of the chemist. A molecule is made up of atoms. Thus one atom of iron combines with two of sulphur to form pyrite (iron sulphide). It is written FeS_2. An ion has been described as an atom or group of atoms, which are positively or negatively charged with electricity.

IT is a good plan to always provide large storage bins for ore either in the mill or at the breaker. There appears to be no objection to having these bins in the mill and at the breaker as well. It is never economy to dump ore from cars upon the ground, to be shoveled up later into cars again. The cost of shoveling a thousand tons will go a long way toward building a bin to hold the ore from which it could be reloaded into cars by gravity.

DURING 1901 there were shipped from a mine in the State of Georgia 747 tons of asbestos, valued at $13,490, and in 1902 the production was 1010 tons, worth $12,400, or about $12 per ton. Asbestos of merchantable quality occurs in Riverside, El Dorado and Tehama counties, California, and also in Gila county, Arizona, in North Carolina, in Maine and numerous other places. A large amount is mined in Canada. A specimen would have small value.

THE practice of scraping mill plates with a chisel is a bad one and is only permissible where the ore is rich, and is not good practice even then. When gold amalgam is removed so completely from the plates, it becomes necessary in the next run to give the plate more attention on this account than would otherwise be required to get the plate in good condition again, and in a mill where low-grade ore is being treated this condition is intensified.

IT is not uncommon to find stalagmites and stalactites of iron oxides forming in mine workings, from dripping water containing ferrous solutions, mostly derived from oxidizing pyritic ore. Assays made on samples of this material in some of the gold mines in California have shown the presence of gold in the iron thus formed, in one instance to the extent of $3 per ton. Whether the mine water contains gold in small amount in solution is not known to Concentrates, but it is not an unreasonable supposition that it does.

THE mineral specimens from North Yakima, Wash., are: No. 1, dolomite with small amount of pyrite, and also copper ore, the latter partly oxidized. This rock often occurs in vein-like masses, and is believed to be the result of alteration of an intrusive rock mass. It is sometimes gold bearing. No. 2, vein quartz with abundant mispickel, (arsenical iron pyrite) probably auriferous. This ore is sometimes rich in gold. There is also a small amount of pyrite present. The greenish-yellow color is due to the arsenic. No. 3 is infusorial earth.

A NATIVE amalgam of mercury, gold and silver occurs, but is rare. It is known in several European mining regions, in Chile and British Columbia. Native mercury, containing no gold, though sometimes a small amount of silver, occurs in many cinnabar mines. It is found usually at or near the bottom or lower edges of deposits of cinnabar, and is due to reduction of the sulphide by natural causes. The appearance of metallic mercury in a quicksilver mine is looked upon by some as an indication of the approaching exhaustion of the ore deposit in depth.

THE specimen of smooth, glossy, green rock from British Columbia, presumed to be ore, is serpentine and of no value. Serpentine is abundant in many parts of the world and occurs in dike-like sheets and irregular masses, sometimes of great size. It is a metamorphic rock, due to alteration of basic olivine and peridotite-bearing rocks, also from the alteration sometimes of hornblendic and augitic rocks. Serpentine is similar to talc, but the former is completely decomposed by sulphuric acid, and talc is not at all decomposed by it. Serpentine contains more water of crystallization than talc.

A CLAIM located by K. in 1900, and sold by him in 1902 to M., and M. failing to do the assessment in 1903, the claim became subject to relocation at midnight December 31, 1903, and not a minute previous. If K. relocated the claim at any time or hour prior to that date and time the claim was really not subject to relocation. If T. waited until 1904 to relocate he would be legally entitled to the claim, but it is a matter which would probably require the decision of a court. If the claim is valuable it would be wise for T. and K. to compromise and divide the interest in the property, as it would be difficult for either to establish their exclusive rights to the relocation.

IN the metallurgical process as practiced in the mints of the United States, the last portion of a large "melt" of refined gold is allowed to remain in the crucible, and is called a "king." It contains iridium and other rare metals, which, being heavier than the gold and less fusible, settle to the bottom, where they are found as crystals. The gold is dissolved by means of aqua regia (nitro-hydrochloric acid), and the crystals of iridium which may be present are recovered. The iridium has a higher melting point than the gold, and as the heat employed in melting the gold is too low to fuse the iridium, the two metals do not alloy. The "kings" are sold by the Mint to the manufacturers of gold pens, who work them up.

THE most satisfactory way in which to make comparison of the relative cost of various kinds of power is by the cost per horse power per month. Steam, electricity and water power are the three kinds most generally in use in the mining regions of the West. In some districts there is also power derived from gas, gasoline, distillate and other types of engines. No comparison of the relative cost of water, steam and electric power can be given without a complete knowledge of conditions obtaining at the place where the power is to be employed. Free water power is usually the cheapest, and water power bought from water companies is often cheaper than steam. Electric generators require a steady power in order to secure the even operation of the dynamo.

TO PREVENT SKIPS from overturning in a shaft sunk at a high angle, the bail or draw bars must be secured near the top of the skip. But skips of this description cannot be made to dump automatically. Automatically dumping skips have the draw bars secured near the bottom, at the sides, or underneath the bottom, and are provided with a lug on either side, near the top of the skip, which prevents the skip from turning over in a direction away from the rails, but which permits the bottom to be lifted from the track when the upper wheels pass out on the flat track above the ore bin or chute at the surface. Some skips are also provided with a latch, which is released by a lug at the proper point, which permits the skip to be automatically dumped. Grooves for the rear wheels are not necessary, as has been proven at many mines where automatically operated skips are in use.

THE latest volcanic eruption in the United States is not definitely known, but it is thought to be that at what is known as Cinder Cone, about 10 miles east of Lassen peak, in Shasta county, Cal, which is believed to have been in eruption within 100 years. There is every evidence of this eruption having occurred within a recent period. Many of the trees killed by the gases and hot ashes are still standing. At the time of that eruption a large amount of lava welled up in the crator and quiotly flowed down into a large lake, dividing the body of water into two separate bodies of water — Snag lake and Lake Bidwell. After the lava flow ceased there were numerous violent explosions which cast hundreds of bombs into the air, and these are found scattered about the surrounding lava field. Following this cinders continued to be thrown out by the crater, and these accumulated to the height of 600 feet above the lava field, forming a broad flat truncated mass, the ideal type of a cinder cone. There are numerous other cinder cones in that portion of California, but for most part they are covered with timber and brush, and have been extinct many years.

WHERE it is desired to estimate the number of tons of quartz taken from a mine and stacked ready for shipment to mill or smelter, there are several ways in which it may be done. If the ore is to be sacked, after sacking weigh ten or more full sacks and get the average weight per sack. This weight multiplied by the number of sacks will give the total weight in pounds. If the ore be of too low grade to justify the expense of sacks and sacking, vertical walls of the large pieces of ore should be built and the surplus thrown in the interior space. Leveling the top, the cubic contents may be ascertained by measurement and the number of tons by the number of cubic feet in one ton. In the case of quartz, 20 cubic feet. In that of galena, about 6.6 cubic feet. Lead carbonate, 7.5 cubic feet, etc. In the case of oxidized ores of lead, copper, etc., if there be much quartz, lime or other relatively light gangue present, a greater quantity will be required to make a ton. If the ore be too fine to build walls and no bin is available, the weight of the ore may be estimated by forming it into a conical pile. Then measure the diameter of the base of the pile of ore, in feet, square this and multiply by 0.7854. This will give the area in feet. Multiply this result by one-third the vertical height of the cone and divide the result by 20, which will give approximately the number of tons in the pile. Example: A circular pile of ore is 14 feet in diameter and 6 feet high. The square of 14 feet is $196 \times 0.7854 = 154$ square feet $\times 2 = (\frac{1}{3}$ the height$) = 308 \div 20 = 15.4$ tons of quartz ore.

WHERE veins occupy a fault fissure the direction of relative movement of the walls of the fissure may be usually ascertained by comparing the wall rocks on opposite sides of the vein. It is not known that veins occurring in the plane of a reverse fault are better than those which occupy normal fault planes. Careful investigation may show the fact that one portion of a vein may be in a reverse fault, and another distant portion in a normal fault, one wall having swung on a pivot, as it were. Often faults have had a greater lateral than a vertical movement, and the lateral movement is not noticed at all, because no evidence of such movement is sought. The grooves so often seen on the walls of a vein have in most instances been produced by movement subsequent to the formation of the vein, and not infrequently two, three, or even more systems of grooves are found, indicating a long period of movement, the forces operating from various directions. Many believe that the direction of trend of ore shoots is indicated by the direction of the grooves and striations, but the fact that these grooves and striations are found crossing each other proves that they cannot always be depended upon to indicate the trend of a shoot. Moreover, where there are several shoots in a vein, these do not always have the same trend. Two shoots in a vein have been known to have a directly opposite trend, as, for instance, one trends northerly, the other southerly, these two overlapping in depth and forming one shoot. In the early history of a mine the management is often uncertain where to locate the main working shaft, owing to the erratic distribution of ore bodies, and lack of knowledge of their general trend. This is a matter which only the further development of the mine can determine. Where there are very deep "grooves," or rolls in the walls, these are more dependable as indicators of the direction of trend of the ore shoots than mere striations on the polished surfaces of the quartz or wall rocks. In many veins it is clearly evident that the valuable ores have been deposited later than the great mass of the vein. "Pay streaks" are not uncommonly later than the barren portion of the vein accompanying them.

The Pump in Placer Mining.*

Written for the MINING AND SCIENTIFIC PRESS by J. A. YEATMAN.

It is well known that there are many placer deposits that cannot be reached by natural hydraulic heads without great expense. The working of these deposits may be undertaken by establishing a pumping plant and handling the water through giants as in gravity-pressure plants.

The idea is not a new one, but the question of the size and character of the pumping plant has never been determined in a satisfactory mauner until recently.

The event of the step pressure pump for handling large quantities of water against high heads operating at a high efficiency has pointed out possibilities that could not be considered for any other class of pumps.

Step pressure pumps have large capacity, are very much lighter than other pumps for a given capacity, are easily transported and installed, do not wear out like pluuger pumps when handling muddy water, will even handle water containiug sand and small gravel without clogging, or undue wear or great loss of capacity or efficiency. The facility with which the pressure may be raised aud lowered at the will of the operator makes these pumps desirable factors in placer installations where pumping heads are required.

The following description of a placer plant using artificial pressure head produced by one of these pumps, was installed by the writer for the United Iron Works of 32 Fremont street, San Fraucisco, Cal., for Stewart & Hawkins at McCoy, Colo., during the past year, and is of interest.

The accompanying cuts illustrate the general character of the installation.

The deposit was adjacent to the Graud river iu Eagle couuty, Colo. It extended back on a sloping hillside for about 800 feet; it was 12 to 30 feet to bedrock. The material was assorted gravel and sand, including stones up to 7 inches in diameter. The gold was very fine and associated with black sand. The best values were found on a clay stratum close to bedrock. It was considered advisable to install the elevating plant on the lower side of the property and sluice the gravel down to the elevator and send the material through a long sluice, draw off the fines and send them to a gold saving station, consisting of a series of Rose gold boxes, dischargiug the tailings into the Grand river.

The plant was of 100 miner's inches capacity and was for testing purposes for proving the character and worth of the deposit. The power equipment consisted of a 12x14-inch steam engine operating at 160 revolutious per minute, and a 54-inch by 16-foot boiler, which, under working conditions, produced 65 H. P. The pump took its water from the river 150 feet distant through an 8-inch pipe line, and discharged into a 12-inch pipe line 200 feet long, which was split, sendiug part of the 100 miner's inches to the elevator and part to the giant.

The elevator lifted 22 feet vertical aud required 60 miner's inches for its operation, and the balance was used to feed the same after the material had been sluiced close to the elevator. The sluice run was 24 inches wide, 16 inches deep, and set on a grade of 6 inches to 12 feet—twelve boxes, long-riffled throughout, elevated as shown in the cut (Fig. 1). Near the lower end an undercurrent was established and the fines drawn off and seut to the gold saving station. When in operation the water ran 4 inches deep in the sluice. The pump was a 7-inch of the two-step pressure type, having a capacity of 1125 gallons per minute. It was speeded for 160 feet head and operated at 850 revolutions per minute. The pump was set 10 feet above water level to avoid the high water of the spring season. When pumping through the 2¼-inch tip on the giant, the gauge ou discharge line near the pump showed a pressure of sixty-five pounds per square inch, and the giant operator was able to throw a stream 233 feet horizontally, and was able to establish a sluice run 100 feet distant and carry waste into the river, as shown in Fig. 2.

The pump operated silently and without end thrust, and its performance was more than was expected.

The fuel used was pinon pine and cedar, which was laid dowu at the plant for $2.50 per cord. Only two cords per day of ten hours would be required.

Five men operated the entire plant aud were distributed as follows: One man took care of engine and boiler, one operated the giant, one looked after the elevator, another after the gold-saving station, the cook completing the party.

Five thousand pounds of refined concentrates were caught in twenty days' run, before operations had to cease owing to the severity of the weather. Subsequently, advices are to the effect that the ground proved out, and that a larger plant will be installed.

It may be worthy of note that the pressure was raised to 105 pounds per square inch, nearly equal to a head of 250 feet, and its performance closely noted, and it was found in this material that very little advantage was gained. The conclusion was that the best results with fuel were to be had with more water and less pressure—just sufficient to loosen material in place. It was also noted that most gravels, even where packed and cemented to stand in vertical walls, would respond to pressure corresponding from 100 to 160 feet.

It is believed the above method will open up gold deposits yet untouched.

The following tables, showing the duty of giants with given volume of water per minute under stated pressure, together with other data, will be of use to hydraulic engineers and placer miners:

How Bullion is Received, Treated and Paid for at the U. S. Mints.*

NUMBER II.—CONCLUDED.

Written by Frank Leach, Superintendent U. S. Mint.

Upon the receipt of a lot of bullion it is weighed, put in boxes, locked and then immediately sent to the melting room to be put in condition for assaying. All metallurgists know that practically no gold is produced from the ground or the rocks but what has alloyed with it a certain percentage of silver, copper, lead, antimony, zinc, etc. These metals appear with the gold, singly or in combination, to a greater or less degree, and it is the proportion of the silver and base metals to the gold contents that establishes the fineness of the bullion.

To obtain a satisfactory determination of the value of the bullion, in the melting of the deposit there must be a complete mixture of all the metals; in other words, it must be made into a homogeneous mass, so that a chip taken from any part of the bar will truly represeut the character of the metal of all the rest of the bar. The assayer now finds the value of the precious metals in the deposit by determining the number of parts of pure gold and silver separately in 1000 parts of an ounce of 480 grains, which fixes the fineness. Thus we say a deposit is 726 fine, which means that it contains 726 parts of pure gold out of 1000 in a Troy ounce, which would give it a value of $15.00 per ounce. The increase in the number of parts of pure gold increases the fineness and consequently the value per ounce. Practically, each 48½ parts of gold in 1000 is eqnal to $1.00. To illustrate: If the fineness of an ouuce of bullion 726 fine is raised to 774½, the value of the bullion is iucreased from $15.00 per ounce to $16.01 per ounce.

As a rule, by 1 o'clock the following day the Government is ready to pay for the gold it has received from the depositor, the interim is the time necessary for melting, assaying and computing the values. The Government is very liberal in its dealings with the producers of bullion. The weights of deposit are allowed, or measured, to the one-hundredth part of an ounce. Tbe checks against errors in weighing are a guarantee from mistakes in that direction. The weighing is done by the receiving clerk on the finest scales the Government can buy.

These scales are tested and adjusted every few days by an expert employed in the mint, whose entire time is given to the care and adjusting of all the scales in use in the mint, and they are kept in a condition of absolute accuracy all the time.

The weighing is done in the presence of the depositor, and is always checked by assistant to the receiving clerk, and the bullion is not removed from the scales until the register of deposits counts up the weight and compares his count of the weight with that marked down by the receiving clerk and it is found to agree. The fraction of the hundredth part of an ounce inures to the benefit of the Government.

In establishing the fineness of the bullion, or assaying, our Government is more liberal with its customers than some of the old countries. In dealing with crude gold the fineness is determined to one-half of one-thousandth, while the practice in some countries is not to report the fractions of oue-thousandth part at all. In fine gold the United States mints report the fineness to one-quarter of one-thousandth.

There are no deductions made in either weight or fineness in receiving deposits of an ordinary character, but when a deposit is presented containing an excessive amount of base metals, or impurities, in the discretion of the melter and refiner, with the approval of the superintendent, deductions of 0.05 to 0.10 of an ounce are made to protect the Government against the loss which it would sustain in the process of refining if the deposit had been accepted at full weight.

Such deductions, however, are only made in extreme cases.

Gold bullion reaches the mint in various forms. As a rule, the larger mine owners reduce the products of their operations to bars. Deposits in this shape are most desirable, giving less occasion for dissatisfaction than in any other form.

Considerable gold comes to the mint in the shape known as "gold dust," the product of gravel mines. As a rule, this character of deposit coutains more or less impurities in the form of iron oxide, sand or particles of quartz, or minute pieces of iron and lead, much of which is scarcely discernible to the naked eye; but it all goes to make up quite a loss in weight when the deposit is melted. Experience shows that the loss in melting from the sources mentioned ranges from 2% to 6% of the original weight, the average loss running about 3% or 4%.

Tbe inexperienced depositor procures some of this gold, and when he leaves it at the mint, or with any other purchaser of bullion, he thinks it is all gold and can not understand why it should shrink in weight by melting, and is apt to think he has not been honestly treated. It might be well to say here that as soon as a deposit is received by the receiving clerk and weighed, it is put in a box, locked and conveyed to the melting room, where the operation of melting is conducted under the eyes of a person appointed by the superintendent for the special purpose of supervising the work, which is performed by several employes selected for their known character of integrity and skill.

When a deposit is ready for the assay department, it is taken to the sampler, who takes from the bar two samples, which are placed in separate papers; one is marked "A" and the other "B," with the number of the deposit. These samples are then sent in to the assayers, located in another room. They know nothing of the owner of the deposit, or the size of the bar. The two samples are then assayed, each by a different person, and each assayer writes down the result of the assay in his record book, without consulting one with the other. These books are handed in to the chief assayer or his assistant at the close of the day's operations, and he compares the results and reviews the work of the assayers.

If a case should occur where the results of an assay do not agree, then a re-assay is made. If an agreement in results can not'then be reached, it is apparent there is some base metal present in the deposit which prevents a homogeneous mixture in melting, and the bar is sent back to the melting room and treated to overcome the trouble.

A very considerable proportion of the receipts at the mint comes in the form of amalgam cakes, which arises from the clean-up at the mines in the shape of amalgam, and retorting of the same. This form of deposit gives the greatest percentage of loss in melting, for the reason that not one deposit in a hundred is completely retorted. In other words, the miner fails to remove all the quicksilver. Of course, when he brings the bullion to the mint the quicksilver remaining in the cake gives weight to the deposit, and when the bullion is melted and cast into a bar, that process eliminates the mercury and the deposit will show a loss equal to the amount of the unretorted quicksilver present when it was brought to the mint. Amalgam cakes have been received at the mint, which, on the outside, show only a gold color; there was uothing from the general appearance to indicate the preseuce of unretorted quicksilver; but upon breaking the cakes open the center plainly showed that the quicksilver there had not been disturbed. The loss in melting in instances of this kind would be quite large. In reality the depositor has suffered no loss, for he has just as much gold after melting as before. It is the unknown presence of quicksilver that causes him to think he has more gold than is contained in the deposit. The losses in melting of this character of deposits ranges from 6% to 12%, with an average loss of about 8%. If the producers of gold dust and amalgam cakes should provide themselves with a small furnace, melt their bullion and cast it into bars before sending it to the purchasers, there would be removed the greatest source of disappointment in dealing with buyers of their products.

The idea prevails to some extent that people bringing bullion to the mint get back their identical gold in such denominations of coin as they desire. Such a plan of operation of the mint is wholly impractical. To conduct the business under such a system would require each individual deposit to be refiued by itself, made into ingots and carried through all the process of coinage separately from other lots—a procedure which would increase the cost so much that the expense of turning the smallest deposits into coin would probably equal the value of the gold itself. The Government pays the depositor for all the gold contained, and for the silver, with a slight deduction, which is explained in the uext paragraph. The Government does not make any allowance for other metals that may be present in deposits, except for copper, under certain conditions meutioned below.

The Governmeut has found that it is impracticable to extract all the silver contained in gold deposits in the process of parting or refining. By experience it has been determined the proportion of silver that remains with the gold is one-ninety-ninth of the gold contents, and, for this reason, in settling with a depositor, an amount equal to $\frac{1}{99}$ of the gold is deducted from the amount of silver found in each deposit. Consequently, 990 is fixed as the standard for fine gold—that is, bullion must have 990 parts pure gold in 1000 parts to be classed as "fine gold"; the remaining 10 parts of silver is equal to $\frac{1}{99}$ of the gold; hence, the rule of deduction of $\frac{1}{99}$ of the weight of gold in all deposits above described.

The process of assaying is one of analysis, determiniug the proportion of metals in deposits, and custom has fixed 1000 parts as the sum of uuits, each division of which sum represents the various proportions of metal to the whole. Thus, the assayer finds a sample of bullion to contain 800 parts gold, 150 parts silver and 50 parts base metals, the bullion would then be classed as 800 fine, i. e.:

800 parts gold.
150 parts silver.
50 parts base.

1000 parts total number of units.

It is not practicable to have a table of values showing the worth of an ounce containing other than 900 parts of gold.

This fineness has been fixed as the best standard to figure values in all mint transactions, affording the simplest method and guaranteeing exactness in accounts. Therefore, theoretically, we do not know the value of this deposit containing 800 parts gold in each ounce, so we must reduce it to ouuces coutaining 900 parts. We will say this deposit has a gross weight of 50 ounces, so there would be 50 times 800, or 40,000 parts of pure gold in the whole; divide 40,000 by 900 (900 parts of gold bcing the mint standard ounce) and you will have 44.444 ounces standard, or, in other words, you will have nearly 44½ ounces where each ounce has 900 parts purc gold out of 1000 of the value of $18.60½, equal to $826.88. Now, as to the silver, which also must be reduced to standard: There are 150 parts to the ounce, and 50 times 150 equals 7500 parts, divided by 900 gives 8.33 standard ounces, from which must be deducted an amount equal to $\frac{1}{19}$ of the weight of the gold, which is .44 of an ounce, leaving 7.89 ounces of silver which must be paid for at the ruling price of silver, say, 50 cents per standard ounce, the present rate, or $3.94, making a total of $830.82 for both metals.

Charges.—There will be deducted by the Government from the total value of the deposit as determined above, $1 melting charge, 4 cents per ounce on the gross weight of the deposit—50 ounces—or $2, which is the cost for refining the bullion, or, in other words, separating the metals and putting the gold and silver in conditiou for coinage. Iu addition, the depositor must pay for the amount of copper necessary to make coiu of the gold he has brought to the mint, aud that is an amount practically equal to $\frac{1}{11}$ of the standard weight of the gold, or 4.04 ounces, which, at 2 cents per ouuce, amounts to 8 cents, no charge being made for the fraction of an ounce. All the charges on this deposit amount to $3.08, which is deducted from the total value of the gold aud silver allowed in the deposit. The balance is turned over to the owner of the bullion or his order.

The fact that these charges are imposed upon deposits of gold bulliou frequently raises the question in the minds of some of the customers of the mint whether or not there is such a thing as the free coinage of gold. The affirmative sometimes is most energetically opposed until the statement is made that if the depositor should bring his gold already prepared for coinage—that is, with the excess of silver and base metals eliminated, and alloyed with the proper amount of copper as required by law—there would be only one charge made: that of the dollar for melting and determining the character of the bullion. These items of expense are preliminary to getting the metal in shape to melt into double eagles or half eagles.

No part of the cost of actual coinage is taxed to the producer of the gold; that is all borne by the Government. The charges for melting and refining barely cover the cost of the work as required by law.

However, the mints are not money-losing as well as money-making institutions. The total earnings of all the mints and assay offices of the United States for the fiscal year ending June 30, 1901, reached the large sum of $12,381,966.51, while the total expenditure by the Government in the support of the assay offices and the operations of the mints for the same period of time was only $1,737,625.66. This sum not only includes wages, cost of supplies, etc., but the losses and wastages and every known expense; so the net profit to the Government for that year's operations was $10,644,340.85. The net earniugs for the following year were about $1,000,000 less. The report for the last fiscal year is not yet printed.

The bulk of the profit arises from the seigniorage on the silver and minor coinage. The seigniorage, of course, is the difference between the bullion value of the metal in a coin and the coinage value. The larger part, or about three-fourths, of the net profit mentioned above, accrued from the extensive coinage of standard dollars.

* Trans. Cal. Min. Ass'n.

A well attended meeting was held on March 24th at Seattle, Wash., by the charter members of the North Pacific Society of Mining Engineers. Several previous meetiugs had been held, but at this one the organization took definite shape. A constitution and by-laws were adopted and officers were elected. The qualifications of members was definitely fixed, and is confined to "professional mining engineers, geologists, metallurgists or chemists, or persons professionally engaged in mining, metallurgy or metallurgical engineering." The society's affairs are to be managed by a board of five persons, who are the officers. Those elected to serve for the first year are: President, Chester F. Lee; vice-president, Milnor Roberts; recording secretary, F. C. Newton; correspondiug secretary, P. C. Stoess; treasurer, C. E. Bogardus. It is the intention of the society to present papers and have discussions ou matters of mining practice, to have addresses and informal talks from prominent geologists, miniug engineers and other specialists who may be in Seattle from time to time, as well as from its own members. Open meetings will be held, to which those interested in the subject to be discussed will be invited. It is intended that this institution shall gather together the technical men of that section who have to do with mining, as well for their mutual acquaintance and benefit as the advancement of the mineral industry of the Northwest.

Relation of Employer and Employe.

A somewhat unusual social fuuction was carried out recentlу at Chloride, Mojave county, Ariz., which was so much of an innovation that it can not fail to be of interest to mine managers and their employes, as well as to the employer and employe in other branches of industry. The occasion was a diuner given to the employes of the Pennsylvania & Southwestern Development Co. (which has recently taken over the Minnesota-Connor mines and other properties of the Philadelphia & Arizona Mining Co.) by the president and general manager of the compauy, Franklin H. Griffith. After dinner, Mr. Griffith addressed the men in the following words:

Men, I look into your intelligent faces and am proud of you. I came among you a few weeks ago a stranger—a tenderfoot—from the East. To-day I look at you and feel I am among friends. You were selected from among many applicants for work, and I feel I have about me the best men in this part of the country. It would not be proper for me to say all the best meu; but I don't believe there are any better.

You have taken the keenest interest in your work; beeu ever ready to willingly do the tasks assigned you and seeing and doing many things of your own accord. Time—as to hours—did not seem to be the essential thing with you; but you have faithfully and conscientiously performed your duties and ever been looking to our interests.

It is not advisable for the general manager to go about commending individual acts; but not much escapes his uotice; therefore, I have seen your close attention to duty with much appreciation, and that is why I am proud of you; and I am proud of myself in knowing I have made uo mistake in pre-judging you.

Some one must hold the reins, and that is the part of the general manager. Each man knows his own work, but the general manager must know and keep in touch with all. He must do the directing. His guiding may not always coincide with your ideas, but you must remember he may know things and conditions of which you can necessarily have no knowledge and he is making his decisions for the best of all and from the best of rcasous. A single decision ofttimes involves thousands of dollars, for which he is held accountable by his associates; so do your duty at all times, and be sure he is doing his.

I expect to know every piece of machinery, every part, and every bolt and nut and their different uses, from the bin that first takes the ore, to the car that wheels out the tailings, and even the engine and boilers, so I can take auy man's place in the mill or out of it; not that I want your jobs—I want each of you to hold them—but I am going to be able to take them.

To our company I am its president; to you in your hours of work I am your general manager. I hope at times we may have pleasant occasions, such as this, when we can meet together socially and learn to know each other better; but I would ask that at all times you let me be your friend. As you know, everything has been shut down for many months. You kuow with what feeliugs of hope our mill whistle will souud throughout the valley to-morrow and many will take fresh courage from its voice calling you to work. We have one of the largest and best equipped plants and properties in Arizona; so let us all pull together for success.

As it is with the machinery in a mill, so it is in the industrial, financial and social world. He who can not or does not keep pace with the work and rapid advaucements of the times must drop out of the race and fiud his place lower down. It is either growth or decay, progression or retrogression. This is the inexorable law of the universe. The world recognizes with approval but one element, and that is success. It merely tolerates the mediocre and has no use nor makes no excuse for failure. The man who receives $3 per day and does only $3 worth of work never succeeds to be worth more, and is apt soon to be worth less. But the man who gets $3 and does $4 or $5 worth of work must eveutually become a $4 or $5 man, and, as his value increases, so must follow his compensation.

A man has been given brains with which to work as well as hands and feet, and he is supposed to use them, else he cau never be more than a piece of machinery to wear out and become useless.

Not only does an employe's time belong to those who hire him, but his brains, his thoughts and his best work. It is thus that the great industrial and mechanical achievements are made and the world's progress carried on.

There seems to be a very wrong prejudice against corporations. Combiuations of capital and interests are now recognized as essential to the world's development. It would be wrong to condemn all corporations as bad because some are bad. As communities are composed of individuals, so arc corporations composed of individual men. If the men composiug the corporations are bad, the corporations must necessarily be bad; if they are good, so will be the corporation.

My associates look to me for success; I look to our superintendent, he looks to you, you must look to the machinery. You are essential to my success, I am essential to you. And yet I can get along without any one of you. This may at first seem somewhat paradoxical to you; but think it over. I say it in all kindness, men, but we must understand each other. There is uot a man living, no matter how exalted or important his position may be, whose place could not be filled by another. I want you all with me—that is why I have engaged you; but if every one of you would leave to-day, while it might inconvenience me, that mill would run, for others would soon take your places. And, if I should die to-night, another general manager would come to you in my place. So it must and ever will be.

But, men, we are here to make a success, and we will do it. You look to our interests, and I promise you we will look to yours. That is fair. But don't expect too much, nor expect it too soon. Be willing to work for fair wages now, and wait for better. We have made investments of many thousands of dollars and are taking all the risks; give us a chauce to get some of it back. Don't you think we are entitled to it? You term us capitalists and yourselves working men. I say we are all here to make money. If we are capitalists and you wage earners, so then are you capitalists and we wage earners. I know not your financial condition, but I say to you that your best capital is your brains and muscle. Invest them in such a way as will bring you most happiness, but don't forget that it is very elusive, and it is more in the pursuit than in the possession, and you are more apt to obtain it in trying to give it to others.

A Proposed Filter Press Slimes Plant.*

NUMBER II.—CONCLUDED.

Written by FRANCIS L. BOSQUI.

The battery of filter presses was to consist of seven primary aud seven secondary presses of the center-feed, recess-plate pattern, each press to have fifty 42-inch plates. This large battery was made necessary by the thinness of the cake, and by the slow operations of filling and displacing. After the formation of the cake the residual moisture was to be displaced as in the test plant. The discharged cakes from the primary presses were to be dumped on a belt conveyor runuing under a series of presses, and thence carried to mullers, where they would be broken up and mixed with strong solution. The pulp from the mullers was to be elevated to the extractor vat, 35 feet in diameter and 15 feet deep, where treatment would be carried on with eighty parts solution and twenty parts slimes (dry). There were to be three of these vats, so that a seventy-two-hours' contact would be possible. The pulp was to be agitated at intervals in the extractor vats by stirrers or rotary pumps, and then pumped to the pressure tank on the hill (for which a pump would be used similar to that for the settler vats), and would be delivered thence to the battery of secondary presses. The effluent solutions were to be precipitated by means of zinc dust. The discharged cake would contain about 30% of weak solution, which would be the principal cyanide loss.

The estimated cost of treatment in such a plant, treating 100 tons per day, is given in Table I:

TABLE I.—ESTIMATED COST OF TREATMENT PER TON ON THE BASIS OF 100 TONS PER DAY.

Items.		Cost Per Ton
Power—1 pump, 150 gallons, 200 feet head	12 H. P.	
1 pump, 150 gallons, 200 feet head	12 H. P.	
Mullers	25 H. P.	
Elevator to extractor vats	5 H. P.	
Solution pumps	10 H. P.	
Agitating settlers, etc	20 H. P.	
Miscellaneous	16 H. P.	
Total	100 H. P.	
100 H. P. at $7 per month = $700 per month		$0.23
Cyanide—1.75 pound per ton		0.43
Lime—20 pounds per ton		0.06
Zinc—0.25 pound per ton		0.03
Labor—12 men on presses at $3.50 per day	$42	
2 solution and pump men	7	
2 shift bosses	9	
1 roustabout, 10 hours	3	
Total	$61 per day,	0.61
Canvas—200 yards per month	100 per month,	0.03
Miscellaneous supplies and repairs	300 per month,	0.10
Lights	60 per month,	0.02
Heating	30 per month,	0.01
Depreciation, 5%	335 per month,	0.12
Insurance	135 per month,	0.04
Miscellaneous and contingencies	300 per month,	0.10
Total		$1.78

The cost of the plant, allowing $5000 for contingencies, was conservatively estimated at $100,072, of which $48,100 was the cost (delivered) of the presses alone.

The weak points in the method described above are no doubt obvious. The experimental work showed that it would be a slow process, requiring seven or eight hours for the cycle of operations in a press. The cakes formed, though only ⅝ inch thick, were almost impermeable; they could not be sufficiently dried, and it was found impossible to wash them thoroughly. These results led to additional tests on filter pressing a pulp consisting of slimes, mixed with fine sand iu various proportions. It was found, however, that the conditions were not materially improved until a mixture was used of about 100 parts of slimes to 250 parts of fine sand, the latter passed through a 200-mesh screen. This result uaturally led to a consideration of the treatment in filter presses of the whole product leaving the Wilfley tables, after regrinding to a slime everything coarser than 200 mesh. This plan had much to recommend it. The extraction from the sands in the present leaching plant had been unsatisfactory; and as so large a proportion of the crushed product would already pass a 200-mesh (about 55%), the problem of regrinding the remainder did not seem an overwhelming one. It was only necessary to determine whether the considerably increased extraction would offset the additional cost of filter pressing, as well as the increased initial cost of a plant.

This new feature involved the regrinding of about 120 tons per day. Various forms of grinding machines were considered, and the tube-mill finally chosen as best adapted to the purpose. It was ascertained that two of these mills, 5 feet by 22 feet, requiring about 45 H. P. each, would do the work. A series of determinations made with a 6-inch laboratory press, which were confirmed with a 24-inch press, demonstrated that the maximum time taken up by the cycle of operations in a press would be about five hours, or that each primary and secondary press would have to be emptied five times in twenty-four hours. That this mixed pulp did not admit of more rapid pressing merely proved the impermeable and refractory character of the slimes. But there were several points in favor of the new method: A cake could be conveniently formed as thick as 2 inches, admitting of the use of the distance frame-type of press, of much larger capacity than a recess-plate press of corresponding cost; and the cake being more grauular admitted of perfect displacement and thorough washing and drying to as low as 22% moisture.

For the double filter press treatment of 266 tons per day, there would be required sixteen 42-inch 60-frame presses, holding seveu tons each, or fourteen 48-inch 50-frame presses, holding 7.5 tons each, or twelve 48-inch 60-frame presses, holding nine tons each. The probability that the 48-iuch press might be impracticable, left us to the selection of the 42-inch 60-frame press as the best size.

A series of tests on this mixed product indicated an extraction of from 70% to 85%. For purposes of safe calculation, however, the probable extraction in practice was placed at 65%.

The proposed method of treatment was, with few variations, practically the same as that for the pure slimes. The tailings leaving the Wilfley tables were to be run into spitzkasten, whose underflow would be led to the tube-mills for regrinding. The material finally reaching the settling vats would therefore be a combination of two products — the reground sand from the tube-mills and the overflow from the spitzkasten. It was proposed to use the present leaching plant for purposes of settling. The five upper vats are 8 feet by 10 inches deep; the lower vats, 9 feet by 8 inches deep. It was found that by settling the slimes pulp in the upper tanks, decanting off the water, discharging the pulp to the lower vats and decanting off more water, a final pulp could be obtained in forty-eight hours which would contain only about 67% water. This material was then to be pumped to the high pressure tank and delivered to the presses as in the case of the pure slimes. Owing to the longer treatment required by the fine sands, four treatment vats would be used instead of three, allowing a four days' contact with a 0.3% solution.

The estimated cost of filter pressing all the material from the Wilfley tables (266 tons), as above indicated, is given in Table II.

The cost of erecting a regrinding and filter-press plant, allowing $5000 for contingeucies, was estimated at $109,602, of which $59,200 was the cost (delivered) of presses alone.

TABLE II.—ESTIMATED COST OF TREATING ALL PRODUCT FROM WILFLEY TABLES (266 TONS).

Items.		Cost Per Ton.
Power—Same as for slimes plant, with addition of 90 H. P. for tube mills, and 10 H. P. extra for mullers, or 200 H. P. at $7 per month = $1400 per month		$0.17
Cyanide—0.75 pound per ton		0.1875
Lime—15 pounds per ton		0.09
Zinc—0.25 pound per ton		0.03
Labor—20 men on presses at $3.50	$70	
2 solution and pump men	7	
2 shift bosses	9	
2 roustabouts	6	
2 men for settlers and classifiers	7	
1 helper	3	
Total	$102 per day,	0 38
Canvas—250 yards per month	150 per month,	0.02
Miscellaneous supplies and repairs	300 per month,	0.035
Lights	120 per month,	0.015
Heating	60 per month,	0.0075
Insurance	200 per month,	0.025
Depreciation 5% on $140,000	583 per month,	0.07
Miscellaneous and contingencies (including labor on tube mills)	750 per month,	0.10
Total		$1.13

Before passing to an estimation of comparative profits, we might indicate the three methods as follows:

1. The present practice of leaching the sands, by which 62.5% of the whole product is handled at a cost of $0.65 per ton, the remaining 3000 tons per month being run to waste as slimes; extractiou of gold and silver from sands 50%.

2. The proposed filter-press treatment of the slimes in conjunction with the above leaching plant,

*Trans. Am. Inst. Min. Engs.

at a cost of $1.78 per ton of slimes; probable extraction of gold and silver from slimes 75%.

3. The abolitiou of the present leaching plant, the regrinding of all sand coarser than 200-mesh size, and the treatment in presses of the whole product from the mill (about 266 tons per day) at a cost of $1.13 per ton; probable extraction of gold and silver 65%.

A study of the comparative values per ton, of ore, slimes and sand, from the manager's annual reports of the Liberty Bell Co., justifies the assumption that the value of the slimes per ton, produced by a given ore, will be about 50% of the value per ton of that ore; and that the sands maintain a proportionate value per ton of about 34% of the value per ton of the ore. This will serve to explain Table III, which gives the estimated net profits accruing from the different grades of ore.

TABLE III.—Estimated Net Profits to Be Derived From the Treatment of Various Grades of Ore by the Three Methods.

Value of Ore.	Value of Wilfley Tailings.	Value of Slimes as now Separated in Cyanide Plant.	Value of Sands as now Separated in Cyanide Plant.	Profits Per Month in Cyanide Plant.
$10 00	$1 60	$5 00	$3 40	$5,250
9 50	3 80	4 75	3 23	4,800
9 00	3 60	4 50	3 06	4,400
8 50	3 40	4 25	2 89	3,950
8 00	3 20	4 00	2 72	3,550
7 50	3 00	3 75	2 55	3,100
7 00	2 80	3 50	2 38	2,700
6 50	2 00	3 25	2 21	2,500

Estimated Profits Per Month from Proposed Slimes Plant.	Profits Per Month from Combined Sand and Slimes Plants.	Estimated Profits Per Month from Proposed Regrinding and Filter Pressing.	Profits now Obtained From Canvas Plant.	Increased Profits Per Month by Regrinding Method Over Present Treatment.
$5,910	$11,160	$11,760	$1,000	$5,510
5,340	10,140	10,720	925	4,995
4,770	9,170	9,680	850	4,480
4,220	8,150	8,640	775	3,965
3,630	7,180	7,600	700	3,450
3,060	6,160	6,560	625	2,935
2,490	5,104	5,520	550	2,420
1,920	4,420	4,480	475	1,905

It was important to determine how low-grade an ore it would be profitable to treat by adopting the method of regrinding and filter pressing all the mill tailings.

The total cost of treatment of the ore during 1902 was $5.51 per ton.

Total cost per ton		$5.51
Cost of cyaniding per ton ore milled	$0.38	
Cost of canvas concentration	0 18	
Incidentals	0 92	0.98
Cost to mine, tram, crush and concentrate		4.53
Estimated cost of regrinding and filter-pressing tailings		1.13
Total cost of proposed treatment		$5.66

Now considering that the total cost of treatment from October, 1902, to March, 1903 (inclusive), was only $5.25 per ton, it may safely be assumed that with certain projected improvements and retrenchments, the cost might be brought as low as $5 per ton. On this basis there remains, after deducting the $0.98 as detailed above, a cost of $4.02 for mining, tramming, crushing and concentrating. Add to this $1.13 per ton for regrinding and filter pressing, and a total cost of $5.15 per ton is obtained. Then assuming 60% extraction in the present stamp mill and 65% extraction from the tailings by the proposed new method of filter-pressing, an estimated total extraction of 86% from the ore will be obtained.

On the assumption of 86% extraction and $5.15 cost per ton, a profit from various grades of ore would result as follows:

Ore. Value Per Ton.	Profit Per Ton.	Ore. Value Per Ton.	Profit Per Ton.
$10.00	$3.45	$7.50	$1.30
9.50	3.02	7.00	0.87
9.00	2.59	6.50	0.44
8.50	2.19	6.00	0.01
8.00	1.73	....	....

The foregoing statements show that a plant for sliming and filter-pressing all the tailings from the 80-stamp mill would be slightly more profitable than a slimes plant added to the present leaching and canvas plants; but that the initial cost would be greater. This excess of initial cost, however, would be more than offset by the profits, since in all probability the extraction by the sliming and filter-press combination method could be raised in practice above 65%.

A conservative estimate places the profits from a combination plant between $20,940 and $69,000 per year (on ore ranging in value between $6.50 and $10 per ton) over and above the profits obtained by the present system of leaching; this on an outlay of about $110,000.

Mexico's Mountain of Glass.

In Mexico, in the State of Tamaulipas, is found a large amount of obsidian (volcanic glass), which has been known since long before the conquest. The Aztecs and other tribes utilized the material for various purposes, but chiefly in the manufacture of knives, arrow and spearheads. Some one in Mexico has conceived the idea of utilizing the natural glass in the manufacture of various utensils of glass. Concerning it the Tampico Post has the following:

"A mountain of almost pure glass has recently been discovered near this port in a section of country almost unexplored and where no foreigner, until recently, has ever set foot. The glass is in layers and can be mined at very little expense, as it is found in huge blocks, that can be taken out without removing much earth. The only question in the way of beginning operations at once is transportation facilities, but the party in charge of the mines is of the opinion that the glass can be freighted by burros to the nearest water course, and then by boat to Tampico."

If the owners of this cliff of glass have found a way to make commercial glass of the obsidian they have made an important discovery. The composition of obsidian is entirely different from that of any artificial glass, and the natural volcanic glass, high in silica, is almost infusible, in fact to such an extent that before the blowpipe only thin splinters or the sharp edges of thin flakes may be fused.

Canvas Tables.*

NUMBER II—CONCLUDED.

Written by H. P. Stow.

The original table was 20 feet long and there was but one of them, which handled the pulp from twenty stamps. Finding the tailings too high, I experimented by building one sluice below the tail race and running a proportional amount of pulp over it, manipulating the sluice just as the whole table was operated. The results obtained were so satisfactory that I added 20 feet to the whole table, making twenty-four sluices 40 feet long. Continuing the experiment with the single sluice on the tailings, assaying the pulp at the head and tail of the sluice, I found it advisable to increase the length of the table still more and added 20 feet more, making a total of 60 feet, so that I had a table of twenty-four sluices, each 22 inches wide and 60 feet long, handling the pulp from twenty stamps, crushing two and one-half tons to the stamp. Upon adding twenty more stamps, I built a second table, the duplicate of the first, and behind it, and then ran half the pulp over one and half over the other. Each canvas was swept once in eight hours, three men being employed on eight-hour shifts at $2.50 per day. The concentrates on the vanners were running about $150 per ton and the canvas concentrates about $100. The tailings from the vanners ran about $1 per ton and from the canvas averaged about 50 cents. This seemed to be pretty good work and we ran on for a long time in that way, the canvas concentrates running from $25 to $50 per ton less than the vanner concentrates.

Upon drying the canvas concentrates they showed considerable fine sand and by panning carefully a richer product was produced, which caused us to experiment along the line of cleaning the concentrates better on the canvas. We then began to sweep the canvas less often, working on the theory, which I am satisfied is correct, that when the pulp first runs over the canvas heavy particles of sand settle in the interstices of the canvas and remain there until dislodged by the heavier particles of sulphurets, hence the longer the canvas is run the more sand will be dislodged and the cleaner the product. We then began to assay and experiment to find out how long the canvas could be run without loss. During these experiments we concluded also that the pulp could be materially increased in quantity over the sluices, and therefore turned all of the pulp over the upper table, picking it up and running it over the second table. Prior to these experiments we were sweeping each canvas, which handled half the pulp from forty stamps, once in every eight hours, and the product was worth about $100 per ton, the vanner concentrates being worth about $150 per ton. After changing and running all the pulp over each table, the product from the No. 1 table jumped from $99 per ton to $194, the material on No. 2 table remaining the same value, or $99. The amount of material caught on No. 1 table was just about one-half in the same length of time, but it was worth twice as much, while that caught on No. 2 table was clear gain, having been lost before. The results were evident on the tailings also, which formerly ran from 25 cents to 50 cents per ton, and now dropped to traces and as high as 25 cents, but usually about 10 cents per ton. As soon as the men got accustomed to handling the pulp in the new way, they began to increase the value of the concentrates on the No. 1 canvas, which they ran up to $250 and $300 per ton, sweeping the canvas once in eight hours. The No. 2 table when swept every eight hours gave concentrates worth $99 per ton, and upon changing to twelve-hour sweepings it gave concentrates worth $169.50 per ton, without any appreciable loss in the tailings, which continued to assay from traces to 10 cents per ton. Reducing the number of sweepings enabled me to dispense with one man, and from that time on two men working twelve hours did all the work, besides some outside work arouud the mill.

I finally added twenty more heavier stamps and continued to use the same two tables, running all the pulp over one and then over the other, sweeping the upper one every twelve hours, the night man making three sweepings and the day man two, thereby having time for outside work.

I have already spoken of the settling boxes which caught the overflow from the concentrator box, and they have proven of great value, as 36% of the concentrates caught on the tables does not settle in the concentrator box, but overflows and is caught in the settling box, and this material is of higher value than the main product—that is to say, that caught in the first three boxes, and after that it gets considerably less valuable and less in quantity, till in the final box it is only worth about $50 a ton, which box does not need cleaning out oftener than once in two years. To illustrate values: The inside box gave $223 per ton, the first outside or settling box $289, the second $231, the eighth and ninth boxes gave $74 and the tenth box gave $53.74 per ton.

Another series of assays gave the following results: Vanner concentrates from $90 to $115 per ton; No. 1 canvas $343 per ton, and No. 2 $250 per ton. These assays set the workmen to thinking and they attempted to increase the value of their concentrates, resulting in their getting material worth from $450 to $500 a ton on the No. 1 canvas.

During the last two and one-half years only twenty stamps have been running and eleven sluices of each table in use, requiring one attendant, who swept the upper canvas twice in twenty-four hours and the lower one once in forty-eight hours, all that is required with the decreased amount of pulp. The man who did the work was an old employe and wished to experiment toward increasing the value of the concentrates, the whole thing being done by the care in cleaning the canvas with the clear water and then sweeping it carefully. At this time the value of the vanner concentrates had fallen off to about $60 a ton and he obtained on the No. 1 canvas concentrates worth $620 and on the No. 2 canvas $372 per ton. In December, 1901, tributers worked the mine, and the sulphurets were cleaued up and assayed with the following results: The vanner concentrates assayed $107 per ton, the fine sulphurets in the settling boxes under the vanners went $285, and the canvas concentrates $740, the two tables being assayed together. A second run gave vanner conceutrates $111, settling boxes under the vanners $270, while the canvas concentrates from the No. 1 canvas went $1091, and from the No. 2 $603 per ton. The outside boxes of the upper canvas went $401, and those of the lower canvas $587. This man finally obtained concentrates on the upper canvas worth $1300 per ton. There were 2500 pounds of that value saved in 100 days.

The newer the canvas, the less the value of the sulphurets, due to its being harder to clean. Assays made some years ago resulted in concentrates worth $310 on old canvas and $173 on new canvas. By sweeping too close a thin layer of sand that seems to be caught first is disturbed, resulting in a lower grade of concentrates. Experience teaches the attendant how hard to sweep. A skilled man will sweep the width of each strip with two strokes of the broom and he walks up and down the sluice that has just been swept so as not to dislodge the sulphurets.

The conclusions I have come to are that length of canvas is more essential than the width or number of sluices, which is proved by the gradual increase of the length of the table from 20 feet to 40 feet, and then 60 feet, and finally running the pulp over two tables each 60 feet long and giving the lower table different treatment from the upper one as regards sweeping; further by the increased amount of pulp without increasing the number of sluices; the increased value of the product and the diminished value of the tailings. I do not believe in pointing out the coarse material from the pulp before running it over the canvas, as the coarse material is an advantage in keeping the canvas clean and clear of the slime that is not sulphurets but gangue, the coarse material cutting it out. It is a very great mistake to use water under pressure for cleaning the concentrates off the canvas, because that is where the loss is originally on the vanners, and consequently the more water used the greater the loss, a fact evidenced by the large percentage—36%—of the material caught in the settling boxes outside of the concentrator box, as described above. An extensive arrangement of settling boxes is very necessary, as long a time as possible between cleaning the canvas to be determined by the appearance of the canvas and the value of the tailings.

The cost of building such a table as I have described, with a suitable building, and covering it with canvas ready to use, was approximately $1000. The cost of operating two tables was: Two men per day of twenty-four hours at $2.50 per man, they doing all the work connected therewith, including cleaning up and running the concentrates up to the sulphuret shed. The canvas cost 44 cents per yard in San Francisco and has an average life of ten months, though some only last seven months, and it has run as long as sixteen months. Two men can take up the old canvas and put the new on a table 60 feet long, having twenty-four sluices, in a day and a half. My tables are lighted by windows at the upper end only and with electric lights at night, a very satisfactory arrangement.

I have the brooms made of the best fine broom straw and well wound, and made strong, and the men always hang them up when not in use, and while

*Trans. Cal. Min. Ass'n.

sweeping turn the broom around once in sweeping each sluice to prevent uneven wear.

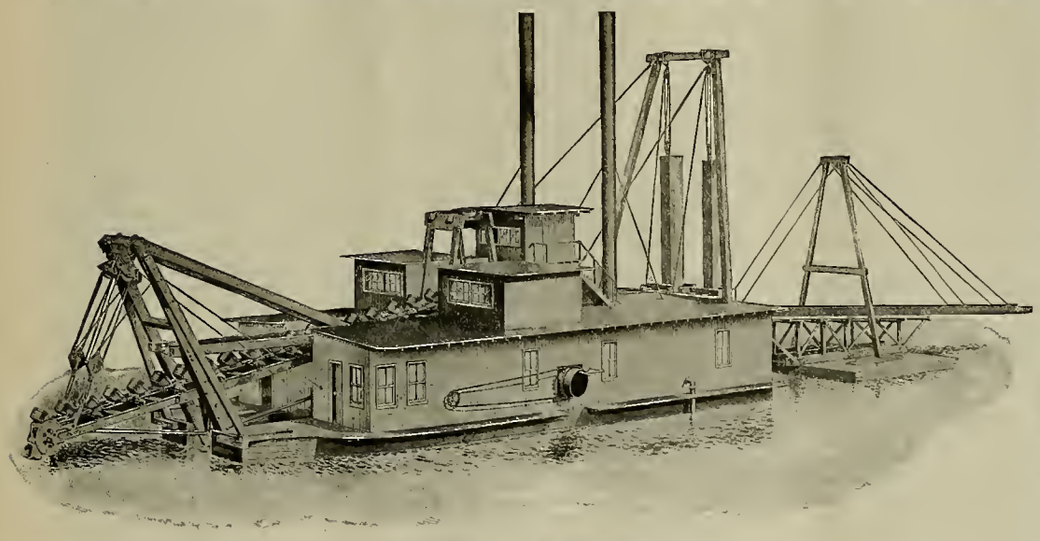
What causes tbe very high value of the concentrates I am unable to state, and I should not expect such high results everywhere, but some experiments that I have made on concentrates caught on different tables lead me to make the assertion that the grade of concentrates could be very materially raised by proper treatment in eliminating a large percentage of the sand. I do not think the table I have described need be confined to gold ores only, as this summer I was given the opportunity by Mr. F. W. Bradley to test it at the Bunker Hill & Sullivau mines in Wardner, Idaho, and succeeded in making a satisfactory test in so far as saving material that was being lost in their slimes. The values being altogether in lead and silver, it would not have proven a profitable undertaking for an outsider to lease the tailings and work them, but I believe it would be profitable for the company to introduce it.

An objection is sometimes raised that a canvas table will cause the vanner men to become careless. I have not found such to be the case. When the canvas man announces that he is doing well and his sluices look fine, I tell the vanner man about his brags, wbo then gets in and hustles.

The most important feature of the canvas table is the results obtained from it, and for years we have taken 16⅔% of the total value of the sulphurets off the canvas, which in many quartz mills is lost.

An Oregon Gold Dredge.

Herewith is illustrated the Abbie J. Champlin gold dredge of the bucket chain type recently furnished by the Allis-Chalmers Co., Chicago, to Champlin & Co., of Gold Hill, Oregon.



Gold Dredge of the Bucket Chain Type.

It is described by the builders as being operated by steam, with 8 cubic feet buckets of the alternate type, built heavy to work hard packed and cemented gravel with a large percentage of heavy boulders, and designed to dig a depth of 45 feet below tbe water line, and a depth from the surface to bedrock of 55 to 60 feet.

The bucket chain they claim to be a new design, patented, and manufactured solely by them. With the multiple lug connection they assert that it overcomes tbe trouble of bending or breaking pins, breaking the back of the bucket or of pulling out of the eye connection, and enables the use of a much smaller pin. A chain of these buckets was furnished to the Centerville Dredging Co., of Centerville, Idaho, with satisfactory result.

The grizzly is of the well-known revolving type, of ample length and diameter, and which has been found to give desirable results with minimum cost of repairs. The grizzly is made with a removable lining so that all that is necessary is to replace the inner lining, which is made in two pieces. A direct connected centrifugal pump is used with spray pipes running through the screens to clean the material thoroughly.

The gravel pump is of special patent, controlled by the Allis-Chalmers Co., lined with steel throughout, the pump taking the material passing through the perforations of the screen and elevating same to tbe sluice box. In the double lift dredge where this pump is used the claim is made that it thoroughly churns the material and puts it in good shape for working to advantage in the sluice box.

The winches for handling ladder and spuds are in one uest operated by an independent double cylinder engine, and for the swinging lines two standard double cylinder, single drum hoisting engines are used. A complete electric lighting plant of ample capacity is also furnished. The Allis-Chalmers Co. furnishes all the iron work necessary for the complete dredge, also erection drawings, together with detail drawings of tbe hull, lumber bill and bolt list, to enable customer to build the hull, and properly erect the machinery.

Cyaniding Gold-Bearing Sulphurets.*

Written by S. B. CHRISTY.

I suppose there are a great many quartz miners who remember the tune when no attempt was made to work a mine in which the free gold that was in the quartz did not pay a profit, all the sulphurets being throwu away. The discovery of Prof. Plattner of Freiberg that sulphurets could be roasted and then chloridized has made a profit of many millions to this State, because it not only enabled what was formerly a waste product to be utilized, but enabled a great many properties to be worked at a profit which had in them free gold enough to barely pay expenses.

There are limitations to the chlorination process. In the first place, it is expensive to roast the ores, and it necessitates the erection of expensive furnaces. Moreover, there are a large number of mines in the State which do not produce sulphurets rich enough to pay for extraction by the chlorination process. There are a great many more mines that produce $25 sulphurets than $125 sulphurets, so, if there could be some way discovered for handling this class of products without chlorinatiug or shipping a great distance to the smelter, it would at once make available a large number of properties which now do not pay a profit for working. Consequently, I have thought the subject well worth the time given it.

The study is full of difficulties, and it is hard to explain the details in a few minutes. In the first place, a word ought to be said as to the composition of the sulphurets. They are not always the same. There are some very distiuct differences in their composition, and in their mode of reacting with the cyanide solution. The simplest are those which contain nothing but iron pyrites and gold. In these there seems to be no doubt that the gold is, in many cases at least, merely mechanically enclosed. The late Melville Atwood gave much attention to this subject, and he has shown me specimens of pyrites with metallic gold thinner than gold leaf on the cleavage planes of the crystals. We have a number of specimens in the University museum with crystals of gold sticking out through the sides of the crystals of pyrites. In all these cases there seems to be not the slightest doubt but what the gold is mechanically enclosed.

On the other hand, there is not the slightest doubt that there are other "sulphurets" in which tbe gold is not mechanically euclosed. It is chemically combined. Notably among these are the gold ores carrying telluride combinations. There are a number of tellurides occurring in our mother lode ores, some quite rich. Besides this there seems to be a class of sulphurets composed of sulphides of iron, together with antimouide and arsenide of iron, in which the gold is chemically combined. There is no doubt but what there are these different classes, and that the latter class, in which the gold is chemically combined, is much more difficult to treat.

Besides these gold-bearing minerals there are the copper sulphides, copper pyrite and bornite, or peacock copper ore, as the latter is sometimes called. These introduce difficulties, owing to the copper conteuts. Theu, zincblende and galena are often present. They do uot, as a rule, seem to have the injurious effect on the treatment that one would expect.

The cyaniding of ordinary quartz tailings, we may say, has been solved. That is, not only the scientific, but the technical and commercial aspect of the problem has been solved. But when it comes to the treatment of these sulphides, it has not hitherto been solved commercially, although I believe it is in many cases entirely feasible to cyanide these sulphides commercially.

There are certain difficulties to be met, part of them mechanical and part of them chemical. The chemical difficulties are uow pretty well understood, and I need not say much about them, only I will lay down as the first proposition to which I call your attention:

The sulphurets should be treated fresh—that is, if we are going to cyanide them with the least difficulty, we must take them just as they come out of the concentrator. We must not let them stand piled up in heaps, to become oxidized and sour, because, when they become oxidized, acid is set free, which destroys cyanide very rapidly, and a number of complicated reactions take place that render successful treatment difficult and more expensive, though not impossible. So, the first thing to be remembered is that they must be treated as fast as they are produced. If they cannot be treated instantly, or within a day, they ought to be kept under water, so as not to be exposed more than necessary to the action of the air. If they are allowed to lie in the air they become rusty and difficult of treatment.

The secoud proposition—probably the most important of all—is that the sulpburets must be in a state of fine subdivision. Nearly all of these minerals I speak of are impervious to water and to cyanide solution, and the solution can permeate them only very slightly. A 70% extraction, for example, is very common on ores of this sort. And let me call your attention to what that means. I will suppose the grains are spheres, and that the solution permeates a certain distance and extracts all the gold. As a matter of fact, it takes all out of the outside and in diminishing quantities as it goes to the interior. But, for the purpose of illustration, I will suppose it takes a shell from the outside and extracts all the gold from it. A sphere from which 70% has been thus extracted would leave a corc two-thirds of its diameter untouched, and it will extract the gold from a shell one-sixth of the diameter. Now, suppose the solution permeates .01 of an inch in a given time, say two or three days. It will extract all of the gold from a particle $\frac{1}{50}$ of an inch in diameter. That is, you take out 100% from such a piece as that, while a grain that is only $\frac{1}{10}$ of an inch in diameter will take a shell $\frac{1}{100}$ of an inch thick, or will extract only 7%. That is, a particle $\frac{1}{50}$ of an inch in diameter will be entirely extracted in that time, and one with a diameter of $\frac{1}{10}$ of an inch will ouly yield 7%. Experience shows that this is the case.

The Utica mine has for some time been treating the concentrates produced by the canvas plant. These are in an extremely fine state of subdivision, and good results have been obtained by their treatment with cyanide solution for several years. Attempts to treat the vanner sulphurets, which are relatively coarse, have not met with success, and it has been necessary to roast and chlorinate these.

I had the pleasure of witnessing some experiments made at the Melones mine, where, under the management of W. C. Ralston, an attempt was made by F. L. Bosqui to cyanide the tailings from the mine there directly—that is, all the tailings that came from the plates were cyanided iu tanks by downward leaching. The results were not entirely satisfactory, and the method was not followed up. While I was there it occurred to me that I ought to investigate the relative extraction of sulphurets of varying coarseness. I took the tailings which had been leached for three days with a 0.2% cyanide solution. I separated them into different sizes by water sorting.

I used a vertical tube, down which the ore was allowed to settle, and up which was coming an asceuding current of water, which allowed only the coarse particles to settle through. The coarse particles from each sort thus collected were afterwards panned to separate the sulphurets, and these separately assayed. When the upward velocity of the water was 2 inches a second—mind you, the original ore only averaged $3 or $4 a ton, and the original sulphurets went about $25—the coarsest that came through under that heavy stream of water went as high as $27. It had been cyanided for three days with a 0.2% solution, and with an upward velocity of 3 inches per second the coarsest of those sulphurets went $27; with an upward velocity of about 2 inches a second the sulphurets assayed $19.63; with an upward velocity of 1 inch they weut $19.01; ½ inch, $14; and ¼ inch, $6.61, while the slimes which settled against the velocity of less than ¼ inch a second assayed only 60 cents. This goes to show very clearly, indeed, that coarseness of the sulphurets is au insuperable obstacle to the thorough and rapid extraction of the gold.

The third important fact to remember is that metallic iron in a fine state of subdivision is a great destroyer of cyanide. In the metallic state, in large masses, as iu sheet iron tanks, etc., the iron does not have much action on the cyanide. An insoluble crust of oxide of iron forms on the outside, which protects it from further action; but when the iron is in an extremely fine state of subdivision it acts very quickly, and if the iron is in the form of an impalpable powder 1 pound of iron is capable of destroying 7 pounds of cyanide of potassium, and as this is worth 25 or 30

*Abstract Trans. Cal. Min. Ass'n.

cents a pound, you can see that it is quite a serious source of expense.

In crushing ordinary quartz ore in a stamp battery, the loss from the shoes and dies runs from 2 to 2½ pounds of iron per ton of ore crushed. In concentrating the ore on vanners in the ordinary manner, nearly all the iron is concentrated with the sulphurets. So, for example, if an ore contains about 2% of sulphurets, to produce 1 ton of sulphurets will take about 50 tons of ore, so we shall have in the concentrates per ton something like 100 pounds of iron. So, if that iron were all fine enough (it is not all fine enough, of course), that which is extremely fine would be capable of destroying seven times its weight, or, if it were all fine, about 700 pounds of cyanide. Of course, most of it is too coarse to do that, but it shows where the trouble lies.

(TO BE CONTINUED.)

Wet Methods of Extracting Copper at Rio Tinto, Spain.*

Written by C. H. JONES.

The ore treated at Rio Tinto is massive iron pyrite containing up to 3% of copper, which has been disseminated through the mass by a secondary enrichment.

The well-known method adopted for the extraction of the copper consists chiefly in allowing huge heaps of the mineral to oxidize under the influences of moisture and air, and subsequently washing out the copper sulphate as soon as it is formed, by running water through the heap.

The application of this system depends largely on the state in which the copper occurs in the mineral. If it exists as chalcopyrite—$CuFeS_2$—the copper will not oxidize by simple exposure to the air, in one case it having taken many years to oxidize 10% of the copper originally present in the ore. If the copper is in the form of CuS, the oxidation proceeds very slowly. The best form for solution is Cu_2S, or copper glance, which constitutes the bulk of the copper in Rio Tinto pyrite. These statements may be made clearer from the following account of the reactions that take place during the oxidation.

When the mineral is exposed to free access of air and moisture, some ferrous sulphate is formed in accordance with the following reaction:

(1) $$FeS_2 + 7O + H_2O = FeSO_4 + H_2SO_4.$$

This ferrous sulphate becomes readily oxidized by the air to ferric sulphate.

(2) $$2FeSO_4 + H_2SO_4 + O = Fe_2(SO_4)_3 + H_2O,$$

and it is due to the action of this ferric sulphate on the copper sulphides that the copper is rendered soluble, as is shown by the following chemical equations:

(3) $$Fe_2(SO_4)_3 + Cu_2S = CuSO_4 + 2FeSO_4 + CuS.$$

(4) $$Fe_2(SO_4)_3 + CuS + 3O + H_2O = CuSO_4 + 2FeSO_4 + H_2SO_4.$$

The reaction No. 3 takes place fairly rapidly and causes half the copper to go into solution within a few months, while reaction No. 4 proceeds much more slowly, and requires, under the most favorable conditions, about two years to extract 80% of the remaining half of the copper.

Here I may add that in the laboratory at Rio Tinto a method has been worked out to determine the state of combination of the copper in any particular mineral. This method depends on the action of the mineral on various solutions under constant conditions of dilution and temperature, and, though necessarily somewhat arbitrary, it shows with considerable accuracy the form of sulphide in which the copper exists, and consequently whether the copper can be readily extracted by washing in heaps.

In practice the method adopted to bring about the desired oxidation is as follows: A site is chosen for the formation of the heap where the ground is sufficiently concave and sloping to enable the copper liquor that is formed to collect and run out at the base of the heap. On the ground is first arranged a network of air flues, made of rough stones and having an internal diameter of 12 inches. Vertical chimneys, 50 feet distant from one another, are built in the same manner and connect with the ground flues. Care is taken that the mouths of the ground flues are kept open and not covered by the ore. The mineral, the lump portion of which has been passed through jaw breakers to be reduced to pieces not larger than from 2 to 3 inches across, is now tipped from side-tip wagons at the highest part of the selected side over and around the stone flues. "Lump" and "fines" are alternately dumped until the height of the mass at the edge is about 30 feet, the upper surface of the mineral being kept level. A heap of this form approximately contains 100,000 tons of ore.

As the mineral is added, the building of the stone chimneys keeps pace, in order to have a clear opening to the top of the heap. The surface of the heap is formed into squares by means of ridges of the mineral, the size of these squares depending on the porosity of the heap. The function of these ridges is to enable the water to be run on locally over the surface of the heap in order to insure that all parts are equally washed and that the water does not run through the heap in channels. A system of gutters is also arranged so that the water can be run onto all parts of the mass. As the heap is being formed, water is run on and the copper sulphate existing in the mineral is extracted; also, the water provides the moisture for the oxidation to take place in accordance with the equations given above. The mineral in the heap is then allowed to oxidize, which it does pretty rapidly, as evidenced by the heat produced, the temperature in the chimneys rising to from 170° to 180° F. As the temperature increases, the surface openings of the chimneys may be closed in order to allow the oxidation to spread through the heap. The surface gradually shows a brownish coloration, due to the dehydration of the buff-colored basic ferric salt that forms on the top of the mass, and its gradual heating up may be noted by this drying action. The greatest care must be taken not to allow the heap to fire, for if once started it is very difficult to extinguish it. When the oxidation has proceeded as far as it is safe to allow it, water is run on at the rate of about 50 cubic meters per hour, until the soluble copper is leached out. The heap is then allowed to reoxidize and the washing is repeated. After about a year has elapsed the surface requires "retilliug," and the squares are rearranged so that the places where the ridges were before are now the middles of the squares. The gutters also are shifted. At the edge of the heap for a distance of some yards the mineral, which has become cemented, holds a considerable quantity of copper salts and is dug down into terraces in order that this copper may be extracted by washing. When the copper is reduced to 0.3% the heap is cousidered washed and the mineral, containing 49.5% of sulphur, is removed and exported as "washed sulphur ore" and utilized for the manufacture of sulphuric acid.

Successful heap washing depends on the efficient ventilation of the mass, the trouble usually being a too great excess of "fines" produced in mining the ore, which cement hard and clog up the air passages.

The copper liquor as it runs from the heap contains some ferric iron in solution, which, as will be shown later, is very objectionable. In order to remove the ferric iron the liquor is run over a smaller heap of fresh mineral known as a "filter bed," which reduces the ferric iron. This "bed" is laid inside a reservoir formed by a masonry dam across a small ravine, and the liquor after percolating through the mineral remains in contact with it until it is required to be drawn off to the precipitating tanks. When the mineral is fresh the reduction of the ferric iron takes place rapidly, due to the Cu_2S, as shown by equation 3, but the iron pyrite itself has an effective reducing action on ferric iron in solution according to the following equation:

(5) $$7Fe_2(SO_4)_3 + FeS_2 + 8H_2O = 15FeSO_4 + 8H_2SO_4.$$

The principal constituents of the liquor as it enters the cementation tanks are as follows, the figures given representing the grams per cubic meter or units per million parts: Copper 4000, ferric iron 1000, ferrous iron 20,000, free sulphuric acid 10,000, and arsenic 300. The large quantities of ferrous iron and free sulphuric acid present are due to the fact that the waste liquor from the cementation tanks after the copper has been precipitated ("salida liquor," as it is called) is pumped back and used for washing the heaps in addition to fresh water, and consequently these solutions tend to become concentrated. The liquor is then run from the reservoirs at about 300 cubic meters per hour through the precipitation tanks over pig iron in order to precipitate the copper in the form of so-called "cement copper" or "copper precipitate." These cementation tanks are arranged in series on the slope of a hill, the liquor passing backwards and forwards until it is discharged from the lowest tank of the series free from copper.

*Abstract Trans. Am. Inst. Min. Engs.

The Panama Canal.

At a complimentary banquet tendered in San Francisco to Mr. C. E. Grunsky, the California representative on the Panama Canal Commission, Mr. Grunsky made the following statements about the canal:

The idea of uniting the Atlantic with the Pacific ocean at Panama has been in the minds of men ever since the first white man crossed the isthmus. Examinations and surveys were made in the early part of the sixteenth century, nearly 400 years ago, and the obstacles to be overcome in carryiug out this great work have been gradually removed one by one, until at last the people of this great nation are in control and with the means at hand to carry the work to successful completion.

The difficulties in the way of canal construction have, until recent years, been less of a character involving engineering skill than such as involves statesmanship of a high order. After all of the failures that have been made in the past a project has been reported to the United States by the Walker commission, whose report is the basis for the acquisition of the properties of the French company, and this commission's plans of a canal best represent the work as it will probably be carried out.

Although the advantage of a sea-level connection between the oceans was recognized, the disadvantages, among others, of increased time of construction and increased cost of such a project led the commission to plan the canal with a summit level about 90 feet above the ocean. The canal is to be made 35 feet deep. It is to have a bed width of 150 feet. It will be 49 miles long, from the 6-fathom line on the Atlantic side to the 6-fathom line on the bay at Panama. The maximum depth of cutting where the canal crosses the continental divide will be 266 feet. In the construction of the canal the amount of dredging and earth work will be about 42,000,000 cubic yards, and 54,000,000 cubic yards of hard and soft rock will have to be moved, of which amount about 5,000,000 cubic yards lie under water. Nearly 4,000,000 cubic yards of concrete will be required and upward of 65,000,000 pounds of iron and steel will, it is estimated, be needed for the various structures on the line of the canal.

From Colon, on the Atlantic side, the canal will extend inland on low ground, closely following the Chagres river for a distance of 17 miles. The canal is there to be closed by a dam and its water surface raised, and the lake formed by the dam will be used as a canal section for a distance of about 14 miles. The next 8 miles will be in the great Culebra cut. The remainder of the canal, about 10 miles in length, will be on low ground, adjacent to the bay of Panama.

It is estimated that the value of the work already done on the canal approximates $40,000,000. This estimate has been made the basis of the proposed payment to the French company. The estimated cost of completing the canal on the lines indicated by the Canal Commission is $144,000,000. It is thought that eight to ten years should be required for the completion of the work. That this is a work of stupendous magnitude becomes apparent when it is compared with such other great works as the Suez canal, opened in 1869, which, with its length of 72 miles, cost about $60,000,000; and with the Manchester canal, 35½ miles long, which cost about $75,000,000. The last Canal Commission assumes that the annual cost of maintaining and operating the canal will approximate $2,000,000. It is thought that under the opening of the canal to traffic a tonnage of about 5,000,000 per year will pass through it and that this amount will be doubled within ten years.

Cost and Speed of Sinking Shaft of New Kleinfontein Co., Benoni, S. A.*

Written by E. J. WAY.

The cost and the speed of sinking a shaft are factors of so great importance in operating a mine that the data given in the table herewith given will be of interest and value to all engaged in practical mining; and for this reason the data are communicated for permanent and accessible record.

The figures of cost cover the period from January 1, 1903, to May 31, 1903, during which time the total depth sunk was 858 feet.

So far as I know, the cost of sinking per foot, $66.90 (£13 15s 11.04d), of a sbaft, of the dimensions 21 feet by 6 feet in hard rock, is the cheapest yet on record; and the speed of 213.5 feet per month, which was attained during May, 1903, is also the best record for speed in sinking in rock so hard as that of this shaft. During the period from January 1 to May 31, 1903, there were 144 rounds worked, involving 4032 holes, of a total depth of 28,963 feet 2.4 inches, which is equivalent to an average depth of 7 feet 2.2 inches per hole bored. These data are of added interest from the fact that the work was done practically by native labor.

COST OF SINKING EAST SHAFT, FROM JANUARY 1 TO MAY 31, 1903.

LABOR, ETC.	Cost. Total. £. s. d.	Per Ft. Sunk. £. s. d.
White wages	3,292 16 0	3 16 9
Salaries	276 8 5	.. 6 5

Totals			£11,836 19s 5d	£13 15s 11d

Total depth sunk, 858 feet; cost per foot, £13 15s 11.04d ($66.90).

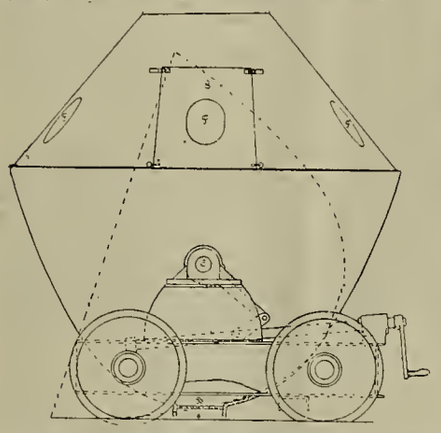
*Trans. Amer. Inst. Min. Eng.

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 22, 1904.

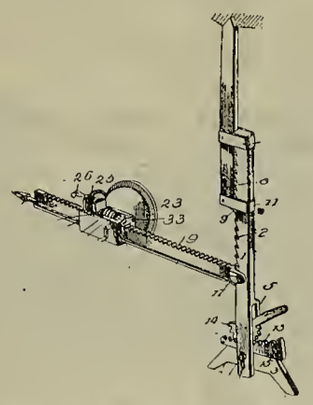
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF DESULPHURIZING LEAD ORES.—No. 755,598; A. Savelsberg, Ramsbeck, Germany.



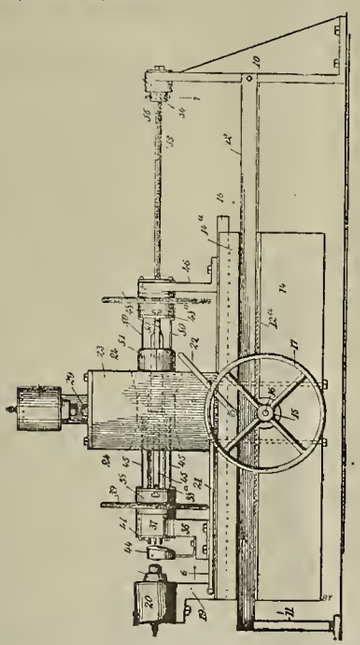
Process of desulphurizing lead ores by mixing raw ore with limestone and subjecting mixture to simultaneous application of heat and current of air in sufficient proportions to complete desulphurization in one operation.

MINER'S DRILL.—No. 755,458; W. D. Cox, Marshfield, Ohio.



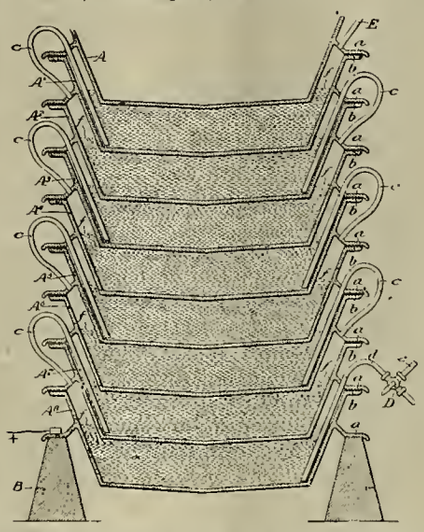
Combination with supporting means for drill-operating mechanism, supporting post, arm vertically adjustable upon post, base secured to lower end of post, pin-and-slot connection between base and post, and independent means for actuating post to raise and lower same upon base.

MACHINE FOR REPAIRING DRILLS.—755,351; J. J. Brossoit, Granite, Mich.



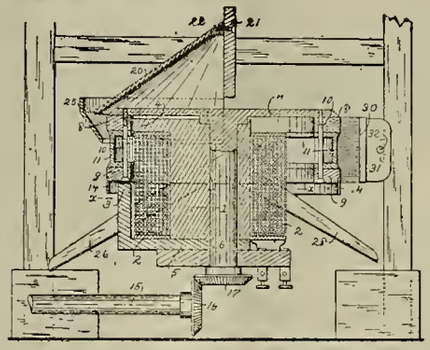
In machine for repairing drills, combination with support and hammer, of plurality of tool sections adapted to coact with hammer, spring arms to which sections are attached, hub with which arms are connected, means in which hub is mounted to turn, edgers also mounted in hub and movable longitudinally of spring arms, and means for operating edgers, means for operating edgers comprising hammer block movable toward and from edgers and hammer operating block.

MANUFACTURE OF SULPHURIC ACID.—No. 755,247; P. G. Salom, Philadelphia, Pa.



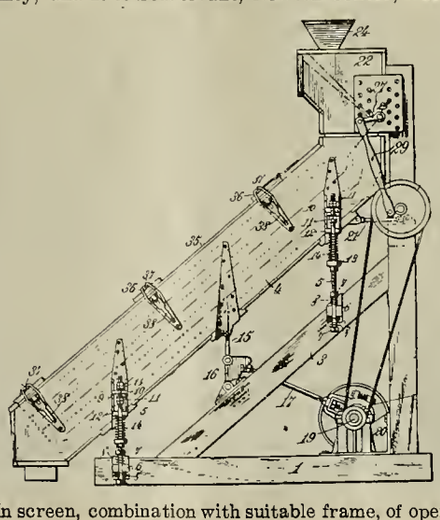
Process for manufacture of sulphuric acid, which consists of passing current of sulphurous acid gas through series of independent but communicating receptacles, each of which constitutes electrolytic cell, and progressively oxidizing current by electrolytic action, in presence of water, during passage of current through series.

ELECTRO-MAGNETIC SEPARATOR. — No. 755,282; M. Dings, Milwaukee, Wis.



Combination of drum formed of magnetizable and non-magnetizable rings revoluble on a vertical axis; an electro-magnet eccentrically located within drum; electro-magnet having one pole piece projecting at one side of magnet into proximity with inner face of drum near one end and another pole piece of opposite polarity projecting from same side of magnet into proximity with opposing end of drum; together with semi-conical distributing shield secured at upper end to framebar 21 and having its base covering side occupied by magnetic pole pieces, and concave reversing shield 25 opposing lower edge of distributing shield.

SHAKING SCREEN.—No. 755,330; T. L. Sturtevant, Quincy, and T. J. Sturtevant, Newton Center, Mass.

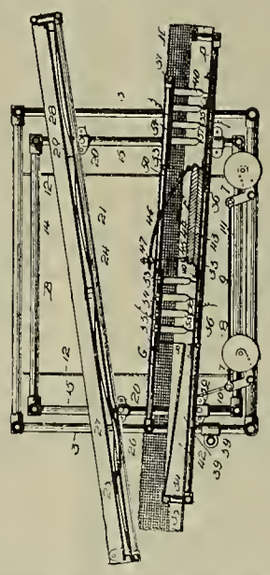


In screen, combination with suitable frame, of open-eared supports on frame, screen supporting rods mounted in supports and vertically movable therein, supporting springs on rods, springs being held between supports and adjustable nuts on rods, screen having supporting ears engaging rods at upper ends, adjustable rigid stops between which screen supporting ears play and by which movements of screen are suddenly arrested, means for vibrating screen vertically on supporting rods, and balancing springs to hold screen midway between rigid stops mounted on rods between screen supporting ears and adjustable nuts.

STAMP BATTERY GUIDE.—No. 755,525; W. S. McDonough, Ouray, Colo.

Guide for stamp mills, comprising girth or rail, continuous solid guide beam extending longitudinally thereof and having vertically extending grooves therein, section blocks arranged in same, blocks having squared ends abutting one against other for rigidity and having vertical grooves adapted to cooperate with grooves in continuous beam and form guideways for stems of mill, bolts extending through section blocks, continuous beam and girth or rail, affording provision for removing any block separately, bolts being provided with squared collars countersunk in continuous beam, to prevent bolts from turning, and elongated washers upon bolts outside of section blocks and extending vertically along blocks depth of blocks, thereby affording provision for equal distribution of strain along depth of section blocks, and lugs on washers for preventing washers from turning.

AMALGAMATOR AND CONCENTRATOR.—No. 755,230; K. Lanius, Denver, Colo.



In amalgamator and concentrator, amalgamating and concentrating trough provided with reservoirs, drain plugs in reservoirs, fixed frame located over amalgamating and concentrating trough, plates upon frame carrying series of fingers which extend down into reservoirs, arrastra located between reservoirs, which arrastra consists of block fixed in bottom of trough, and movable block adjustably connected by rods to rocking shaft, rocking shaft adapted to impart vertical movement to one end of movable block, and means for imparting jerking or jarring motion to the trough.

EXTRACTION OF COPPER FROM COMMINUTED MINERAL MIXTURES.—No. 755,302; E. A. Le Sueur, Ottawa, Canada.

Method of obtaining metallic copper from mixtures containing it, which consists in treating mixtures with ammoniacal solution containing cupric compound or compounds to dissolve desired copper, then removing portion of total copper contents of solution, and lastly in using partially exhausted solution over again to dissolve fresh copper as before.

PROCESS OF TREATING PLUMBIFEROUS ORES.—No. 755,222; E. W. Engels, Dusseldorf, Germany.

Process of treating plumbiferous ores at high temperatures and diminishing chemical and physical reactions taking place between walls of vessels employed and ores or ore products present during treatment, process consisting in conducting treatment in receptacles composed largely of clay and carborundum in relative proportion of not less than 25%, nor more than 90% of carborundum and not more than 75% nor less than 10% of clay.

Mining Summary.

Specially Compiled and Reported for the Mining and Scientific Press.

ALASKA.

At least $50,000 will be spent this year in the Nizina section in testing and opening up the ground bended te Eastern men, says G. C. Hazelett, at Valdez, general superintendent. J. W. Gerard of New York is interested with B. Cochran, the Marcus Daly estate et al. It is net intended to make heavy productien frem the company's properties this year, hut simply to thoroughly test them and ascertain their value. If the ground proves satisfactory, preparatiens will be made te operate next year with hydraulic machinery. The company has forty-five claims. Tbo cempany is taking in fifteen men and twenty-five more will be employed after the soason opens up. Hazelett says work will he guaranteed to this number at $5 per day and board.

The Nome News says that judging from the amount of work in progress the past winter in the mines of Cape Nome mining district tho output of gold this spring will he the largest in tho history of the Seward peninsula. This, too, in view of the fact tbat none of tho larger companies are operating on an extensive scale.

ARIZONA.

Cochise County.

Tho Commonwealth M. Co., at Pearce, is building a cyanide plant, with capacity of 125 tons, to work the mill tailings. The tailings covor thirty acres. The plant will he completed and in operation hy April 20. It will work the tailings from tbe 80-stamp mill that ran fer five years. The mines here are closed down on account of caving ground. A few men are working in new ground.

E. J. Hands, a director of the Hilltop Silver-Lead M. Co., near Wilcox, says the mine is showing satisfactory results. Ore is heing taken out.

The Shattuck-Arizena C. Co. has been incerporated at Duluth, Minn., with T. Bardon, A. Guthrie, M. Pattison, A. M. Chisholm of Duluth and L. C. Shattuck of Bishee as directors, the last named heing manager. Plans for development are under way. The cempany owns 110 acres seutb of Bisbee, being the Shattuck-Costello group.

I. N. Stevens reports dovelopment work progressing on the Lezinsky group, near Bishee. He has opened the vein in the Copper Bluff tunnel to a width of 75 feet. The tunnel is in 300 feet. The ore carried in this dike is a sulphide concentrating proposition. The Copper Bluff adjoins the Chase Creek C. Co. of Arizona, and the dike aheve referred te is said to extend 6000 feet on the property of the latter, whose tunnel will cut this body. The tunnel of the Chase Creek C. Co. is in 520 feet, with a depth of 526 feet.

J. H. Knowles, manager of the Chiricahua Dev. Ce., operating at Paradise, says they have put in additional machinery and are prepared to sink a shaft 500 feet deep and to crosscut 300 feet to open up the veins. A daily stage line has heen put on between the mines and Rodee, their shipping point, on the El Paso & Southwestern.

Gila County.

Gihson & Gihson, who have opened an ore hody on the 200-feot level of their mine, near Globe, are delivering ore to the Old Dominion. They have 3 feet of chalcopyrite. They have dene considerablo development work on their mine, but the ore has paid all expenses and netted the owners a profit, says the Silver Belt. The adjoining claim, owned by P. Nigro, is also producing.

Graham County.

The engines being set up in the Detroit C. Co.'s concentrator, near Clifton, in preparation for douhling the capacity of that plant, will give it 640 H. P.——The Arizona C. Co. has added a converter to its plant, making three in all, which increases the output of Bessemer cepper. For some time past they have been averaging seventy-five to eighty tons per day of Bessemer cepper, which is 99% fine copper. For March the Arizona C. Co. reports output over 2000 tons copper.

D. M. Potter, manager of the Sierra de Ore M. Co., near Clifton, says he is preparing to put in a cempressed air plant. The tunnel is in 630 feet and is making considerahle water (which will he of advantage to the company). The tunnel is heing driven for the main lead. It has already cut two hlind leads which carry geld values.——P. J. Bennett and L. Townsend repert having struck a body of black manganese oxide and copper ore on their claim near the Rock House, on Chase creek. It is said to be a desirable smelting ore for the district.

Maricopa County.

(Special Correspondence).—W. Channel is developing a low-grade gold property near the Phœnix mine, near Cave Creek. ——J. Creath reports making a satisfactory cleanup from his last run of the arrastra on the Broadway ditch. —— A. S. Mills is developing a copper prospect in Cave Creek district, north of Phœnix.

The White Tanks M. Ce. is working men in developing its preperty and taking out ere for the smelter at Wickenburg. —— G. Hamlin says development work centinues at the Reliof mine, 15 miles nerth of Peoria.

H. E. Kell has bought the 5-stamp mill at Buckeye. —— G. Fleming will make a mill run on ore frem the claims of the late C. Fleming, near Cave Creek. Tho mill is run by water pewer.

Phœnix, March 28.

Mohave County.

The Rattan-Ruth greup, below Silver Creek, near Chloride, will be worked by the Premier Con. M. Co. The Rattan is equippod with a hoisting plant and it is proposed to devclop the mine to a depth of 500 feot.——The Minnesota-Connor mill is running on ere from the combined properties. It is proposed to supply the lack of water at the mill by pumping water from the Morrimac mine, and a plant will be put in fer that purpose.

The Mohave G. M. Co. is werking men on tho Midnight mine, near the Roosevolt group, near Acme, and is gotting out gold ore, says the Mohave Miner. Tho ere heing feund in the shaft is a sulphide. It is proposed to sink tbe shaft farther. On the J. B. Lane, sentb of the Leland, tbo company is sinking a shaft in ore. The ore vein is 18 inches in width and is said to carry $80 per ton. On the Leland and Mitchell the company is stoping a goed grade of ore. The mill is working ten stamps. With the opening up of the new ore hodies in the outside mines ard the operation of the cyanido plant, the mill will be run to its full capacity.

A wagon road is heing graded from Vivian to Silver Creek, near Cbloride, thence to the Burlock and Black Mountain mines to the north. The road reaches the Burlock and Black Mountain mines, hut there is ½ mile to he completed on the Vivian end of the route.

The Kennan mill, on the San Cloud mine, on the lower Sandy, south of Kingman, is ready to start dropping stamps. The mines are heing developed and hodies of gold ore are showing.——B. Blanchard of Phœnix is working men on his mining claims on Bill Williams Fork. On one of them three shifts are sinking a shaft and a hody of gold-copper ere has heen opened up. Blanchard has three camps on tbe Fork and in all the mines ore is heing ohtained, says the Mohave Miner.

Santa Cruz County.

J. M. Bailey, of San Francisco, Cal., for Eastern men, has bought for $100,000 the Wandering Jew mine in the Santa Rita mountains, near Nogales, says the Berder Vidette. The Wandering Jew is a silver-lead proposition.

B. Daniels is increasing development on the Huntington greup of mines (formerly the Bextrom), west of Nogales 16 miles and 2 miles north of the international line. He has run a tunnel 360 feet, cutting feur ledges at depth of 375 feet, yielding silver ores. The fourth or main ledge he reports showing high-grade sulphides of silver.

The Humholdt M. & R. Co. has heen organized and has taken over the Trench mines and adjacent properties near the World's Fair mine, near Harshaw, in the Patagonia mountains. This group includes the Humholdt, Josephine, Good Luck, Red Bird, Mocking Bird, Chicago and Indian Chief. The officers are C. N. Thomas, C. R. Brown, R. Farrel and P. E. Murray, the last-named heing manager. These mines have not heen worked since 1897, when they closed on account of lew prices of lead and silver. There are two shafts, 500 feet deep, 250 feet apart, connected, and with 3300 feet of development work on the levels. The company will unwater the workings, extract and concentrate the ores already developed and do further development.

Yavapai County.

The White G. M. Co., operating a group of gold claims in Black Rock district, south ef Big Bug, has let a contract for 300 feet of sinking, says Superintendent L. White. The group has 1200 feet of development work. The ore is free milling and runs $5 a ton. The work has been done on two claims.

The framework of the aerial tramway for the Bradshaw Mountain C. & S. Co., near Crown King, is completed, and stretching the wire rope is under way. By April 15 it is expected the tramway will he in operation.

The Pick and Drill M. Co. is putting in a whim and will increase development work. The company owns a group of claims adjoining those of the Baumann C. Co., in Agua Fria district, near Prescott.

ARKANSAS.

Boone County.

The Susquehanna mill, near Harrison, is turning out cencentrates which are hauled te Harrisen. —— The McIntosh mill is again in operation after several years idleness.

Cincinnati, O., men have erganized the Cincinnati Zinc Ce. and have bought properties in the zinc fields of Boene and Marion counties. They are developing the same. The company intends to operate in connection with its zinc mills a smelter, and will handle ore for entire district. M. L. Henderson, ef Cincinnati, O., is president, with E. Lyons, H. N. Bankard, Jr., W. D. Henderson, D. Weiskopf, L. C. Strauss, A. Ullman, A. P. Campbell and M. C. Cartall, directers.

Marion County.

Tho new lead and zinc mill at Dedd City, built by Iola, Kan., parties, is in operation.

CALIFORNIA.

Amador County.

(Special Correspondence).—The Phœnix reduction works at Drytown has heen sold to the president ef tho Shenandeab M. Co., operating near Plymouth. It is understood the intention is to treat the concentrates from the Fremont Con. and the Bunker Hill mines, near Amador City.

A Cbicago, Ill., company is reopening the Burlingten mine, seuth of the Balliol mine, near Sutter Creek, and will put in machinery. F. O. Courtmarsh, of Mokelumne Hill, is manager.

E. C. Loftus has hought the hoisting plant of the Balliol mino and, as soon as the reads are passahle, will take it te the Santa Ysahel mine, near Quartz, Tuolumne ceunty.

Progress is heing made on the preliminary work for the proposed electric railread from Ione to Sutter Creek and Jackson. Jackson Dennis, of Sutter Creek, is interested in the project.

Sutter Creek, March 30.

T. A. Marsino says the Union Flat mine, near Volcano, has beon opened up, and the company is taking out gravel. This gravel lies under the lava cap, and sinking and drifting is dene to get it to the surface for washing.

Calaveras County.

It is reported that the Mountain King mine, near Hodson, has been sold to Allen & Littlefield of San Francisco, who prepose to put up a 60-stamp mill.

At West Point several properties are ready to he opened this spring. Of these, is the Old Buns tunnel, ewned hy W. Congdon, A. Lund and W. Shultz, and bonded to M. Hitchcock. The ledge averages 2 feet and the ore is said to run $60 a ton in gold. They are sinking. In the spring machinery and a hoist will he put in. The Leckweod, Blazing Star and other mines are idle at present, hut the Blazing Star dump is heing sorted and said to be paying. A 5-foet ledge ef ore is said to show in the bottom. The Continental is working and will put on men. The North Star mine, owned hy J. Goldson, reports having struck another ledge running 8 to 12 inches in width. A goed many small properties are heing worked and several arrastras are running.

Work will he resumed at the Finnegan mine, near Angels.——Operations at the Spring Gulch mine have heen suspended temporarily on account of excess of water.

Inyo County.

J. Coulter, of Randshurg, has hought the 2-stamp mill at Teagle's and will move it to his mine at South Park, in the Panamint Range, near Ballarat.

The 10-stamp mill of the Millspaugh M. & M. Co., at Millspaugh, was started last week.

Kern County.

W. H. Nelson and G. Philips have leased the Magpie mine, near Randshurg, and have hegun werk.——It is reperted the Suspension Ridge M. Co., operating in the Argus Range, has started work on its group.——Shipsey & Montgomery have a lease on the Hector claim of the Ashford M. Co.

Nevada County.

The California Grass Valley G. M. Co. has heen organized to develop the California mine, in Deadman Flat district, 3 miles southwest of Grass Valley. The officers are G. R. Tuttle, I. Haas, L. P. Larue. Operations will hegin this menth.

Plumas County.

Superintendent Kling of the Emigrant Hill mine at Elizahethtown, owned hy Seattle, Wash., parties, has men at work cleaning out a ditch of the Plumas Water Co., which serves the mines in Elizahethtown district. He also has men cleaning out a cut on Emigrant hill in preparation for operations at that point.

In the shaft at the Colonial mine, near Quincy, a heavier pump is heing put in. The bedrock is comparatively seft slate, says the Independent. The shaft drains the heldings of the Colonial Co. lying seuth of it.

San Diego County.

The stamp mill ef the Cleveland-Pittsburg M. Co. is in operation again with 200 tens of gold-bearing ere on the dump.

Shasta County.

The Old Diggings mine en Sacramento river, near Redding, has been sold te the Broda M. & S. Ce. ef New York for $40,000. It is said the company will build a smelter. The plant will be en a site near the Texas mill on the Sacramento river. It will have a capacity of 100 tons daily. The main ore body of the Keystone is said to he 150 feet from wall te wall and several shafts have been sunk en it. There are eight claims in the greup and they adjoin the Texas mine en the northeast. There are several smaller ledges in the group containing quartz ere which can he used for flux. One of the ledges carries values in gold. Tho main ore hedy carries peacock copper ore and specimens show native copper.

Siskiyou County.

The Johnsen mine at Oro Fine, which has been closed down for fifteen years, has been bonded to the Medina M. Co. of Washington. This company is operating other preperties at Oro Fino, and will open up the Johusen mine this month. The mine will be put in eperation as soen as the weather permits sinking a shaft from the 400-foot level. A 10-stamp mill and the Barker ditch, carrying water right from Kidder creek, is included in tbe salo.

Full operations continue at the Smuggler mine on lower Humbug creek, near Hawkinsville, ground sluicing with plenty of water. The top ground is sluiced off for 20 feet down, leaving 10 to 15 feet of hedrock gravel for hoisting into sluices hy derrick.——The McKinley quartz mine on Humbug has men getting out gold-bearing quartz and running a tunnel.

Tuolumne County.

The Black Oak mill, near Soulsbyville, is drepping twenty stamps. About twenty men are at work, but this number will he increased.——The Vine Springs mine, near Columbia, continues making hullion shipments, and in the past five weeks $6000 has been sent eut, says the Independent.

A strike is reported mado on the 600-foot level of the Bell mine of El Rico M. Co. at Tuttletewn. While cutting a station at that point, 10 feet of a vein of high-grade milling ore was opened up. Work is progressing on the 20-stamp mill.

C. W. Sheridan, F. O. Lancey and D. B. Gilliam have started work at the Alta claim, 6 miles southeast of Groveland. There is a 100-foot tunnel on the claim, and tbis will he run to cut the vein.

The water in the Rawhide mine, near Jamestown, has heen pumped out helow the 1300-foot level. The mill is dropping forty stamps. At the App mine they are operating forty stamps. More men will he added.

The Eclipse G. M. Co. is preparing to increase development work on the Markham and twelve adjoining claims near Groveland. The properties comprise 220 acres, says Superintendent De Sallier.

Over 30 feet of snow is reported on tbe summit, assuring a good water supply for the Mother Lode for this season, says the Banner.

The demands of the union miners out on strike at the Rawhide and App mines, near Jamestown, are given as follows hy the Mother Lode Magnet:

All underground men	$3 00
All surface men (minimum)	2 50
Hoisting engineers, for eight hours	3 25
Amalgamators, for eight hours	3 00
Concentrator men, for eight hours	3 00
Chlorination men, for eight hours	3 00
General blacksmith	4 00
Tool sharpener	3 50
Head timberman	3 50
Sawmill man	3 00
Carpenter	3 50
Pumpman	3 25

Nine hours day and eight hours night to constitute a shift's work. Abolition of compulsory boarding house. Doctor fee of $1 per month to be optional with employes No discrimination against any union men for any part they have taken in this strike. That the App difficulty he settled in conjunction with and on the same basis as the above. The discharge of all men now employed at the App mine.

At the Duffield mine, near Carters, development work continues. Ore is still heing hauled to the mill and the stamps are dropping The ore is said to yield $20 per ton in gold and carries sulphurets also.——Glines & Barnes, having a hond on the Black Hawk mine, near Seulshyville, are unwatering and retimhering the shaft.——Superintendent A. Bryant has men at work on the Cerdova mine, near Arrastraville, and three eight-hour shifts are sinking.

Yuba County.

The Priestly dredger on the Yuha river, near Smartsville, was carried down the river and wrecked during the heavy storm of last week. It had not heen in operation recently. The Yuba river

reached a height of 20 feet at Marysville, and at the Government barrier sites at Daguerre Point the pile driver and equipment were carried away.

COLORADO.

(Special Correspondence).—The smelters and reduction plants have declared a reduction in treatment charges on certain ores. With treatment charges at a minimum, in addition to the rich strikes being made, mining in all sections of the State is improving.

New oil wells are being struck in the Florence field in Fremont county. Prospecting for oil in Boulder county and other fields continues. Drilling in the Debeque field, Mesa county, is progressing satisfactorily.

Suit has been commenced between the Theresa and Golden Cycle Cos. at Cripple Creek over the apex rights, the Theresa being complainant.

Denver, March 29.

(Special Correspondence).—A party of Pittsburg, Pa., mining men has offered $100 for the best article written by a School of Mines student on a new and cheap method of handling gold ore that cannot be treated economically under existing conditions by either concentrating or smelting.

Golden, Colo., March 28.

Boulder County.

J. Annear, superintendent of the Wood Mountain mine at Wallstreet, says the mill and mine are being put into shape to resume operations. Preliminary work in way of repairs and changes at the mill has been done. Additional machinery, including slimers, will be put in.

Erie, Pa., men have incorporated the Erie & Colorado C. Co. to take over and develop the copper dyke running through the South Magnolia district, near Eldora, says the Eldora Record. The properties embrace half a mile on one of the dykes running through Magnolia district, said to he extension of the dyke being developed by the Calumet C. M. & S. Co. The lands of the Erie & Colorado Co. are near the Moffat railroad.

Superintendent J. Roboson of Georgetown is opening up the tungsten properties of J. J. Trevarton in Nederland district, near Boulder, and has put men to work.

Clear Creek County.

Leasers in the Mendota mine, near Georgetown, report satisfactory results, and a heavy tonnage is going out. O'Connell & Barmettler, who have bought the Sipe lease on the Frostberg vein below the Victoria tunnel level, have their hoisting plant in operation and have begun shipping. Sinking will he continued, after which a number of drifts will be run for developing the ore body. There are several sets of leasers at work and all are taking out high grade ore. Manager J. Old says he will replace the compressor plant with heavier machinery in order that deeper and more extensive development work may he done.

The Swan group of mines on Silver creek, near Georgetown, have been hought by R. C. Wyvell et al. of Minneapolis, Minn., and a company will be organized. A heavy plant of machinery will be put in. This mine is southwest and near the Joe Reynolds mine.

Chaffee County.

The United States G. & C. M. Co. has heen organized at Salida for operating in the mining districts adjacent to Salida. The company is composed of Pittshurg and Philadelphia, Pa., men. It has a bond and lease on the Independence mine on Cameron mountain, and is preparing to equip it with machinery, says D. Heaton, manager. In Badger Creek district he has hought the Copper Glance mine. On the Independence he will hegin sinking the shaft as soon as machinery can he placed. The Independence is in Cameron Mountain district. The shaft is down 295 feet and shipments of high-grade ore have heen made. The company will sink the shaft to 500 feet.

Custer County.

The Murphy M. Co., operating the Silver Bar mine, will build a 200-ton reduction plant. Work of construction will begin this spring. Development work is increasing, says Manager Murphy, of Florence. The mill will be so built that it can he enlarged to 500 tons a day capacity if necessary. D. J. Patterson of St. Louis, Mo., T. Gardner and E. P. Thompson, of Lawrence, Kan., are part owners.——The New Kaolin Co. has hought additional ground and now has 1200 acres, including an option on the W. B. Wadsworth claim. Its holdings extend from the city limits of Silver Cliff to Rattlesnake mountain.

The Wolcott G. M. & M. Co., which has ore reserves in the P. & O. mine, near the Bassick mine, near Silver Cliff, is planning a mill to treat the ore on the ground. This company will also make other surface improvements at same time.——The Valley M. Co. is preparing to reopen its Camel mine, and has begun unwatering the shaft.

Dolores County.

The Smuggler-Alta group of mines, on the Dunton side of the range from Rico, will be worked during the present season, says Manager Larson, who has put men on cleaning up and retimbering.——The mill at the mouth of the Group tunnel, near Rico, is turning out concentrates.

El Paso County.

Superintendent J. D. Hawkins of the United States R. & R. Co. says arrangements are made for building a $15,000 cyanide plant in Colorado City and work begun. The plant will be run in connection with the Colorado-Philadelphia mill, and 20,000 tons of the dump will be handled per month until the 1,000,000 tons in vicinity of the company's property is all treated. Superintendent Hawkins also says the Philadelphia mill will resume handling Cripple Creek ore this week. The cyanide plant will be built for handling "weathered" tailings, and will consist of a number of open cyanide tanks with necessary mechanical adjuncts. The chlorination process at the Colorado plant will not be changed, hut that part of the mill will be utilized to treat the dump in connection with the cyanide plant.

Gilpin County.

Stewart & Co. of Denver are working the Smuggler mine in Moon gulch, near Central City, under lease and bond, and they are sinking the shaft on the vein and will do other development work. Work on the tunnel has been discontinued temporarily, says Manager H. A. Stewart.

The Blue Grass M. Co. continues running its 10-stamp mill steadily on ore from the Champion dump. The group is at Phœnix and developments are heing kept up at the Lone Star and Tenderfoot mines. Iowa men are interested.

The Gunnell shaft building and plant of machinery, near Central City, were destroyed by fire last week. Superintendent Neldemeyer has hegun work clearing away and will put up new buildings and heavier machinery. The property is owned by the Gunnell G. M. & M. Co. It is estimated the damage to the machinery, loss of building and probable damage to the shaft will represent a total of $50,000.

Hinsdale County.

H. A. Avery of the Klondike M. & Mfg. Co., owning the Black Wonder group at Sherman, near Lake City, says he is preparing to further explore and develop the Black Wonder vein.——C. Forherg resumed work last week on his Double Standard crosscut.——Ten men have been added hy the Hanna M. Co. to the numher at work.

Men are at work getting the Hidden Treasure mine and mill, near Lake City, in condition to resume operations, says Manager P. C. McCarthy. L. Kafka has the lease.

Lake County.

In Upper Evans gulch at Leadville the Best Friend mine is closed down on account of had air, hut the lessees are planning additional machinery. They have driven a tunnel 1200 feet long, connecting with the Best Friend shaft. The mine is operated hy Priddy, Harvey & Thielan, under lease and contract.

The Fryer Hill M. Co. at Leadville is continuing work on its properties and is maintaining shipments of ore to 2500 tons a month, says Manager Newell.

Operations have heen started up hy A. Dyatt through the Mikado territory, near Leadville. He has a lease on the Allegheny mine, which he formerly worked. The work will be conducted through the shaft of the Mikado mine, at depth of 800 feet.

La Plata County.

The Empire G. M. Co., composed of Canon City men, has a group of twenty claims in the mineral helt 16 miles east of Durango, on Small Hopes mountain. Men are at work and shipments of ore that run $100 per ton are going to the smelter. At depth of 200 feet the inflow of water was so heavy that deeper development could not he done, so the company will start a 1500-foot tunnel into Small Hopes mountain, which will afford drainage of the veins traversing it. To facilitate work on the tunnel, company has air compressors, machine drills, piping, ore cars and rails on the ground. The tunnel will cut the Small Hopes vein at depth of 900 feet and at same time develop territory on line of tunnel.

San Juan County.

The Green Mountain M. & M. Co. proposes huilding a concentrating plant near Silverton. The waters of Stony Pass and Cunningham creeks will be utilized for steam power.——R. R. Barr has started work on his group of claims on Eureka mountain, near the Sunnyside mine, near Eureka. One of the claims carries the mineral stephanite ("hrittle silver").

San Miguel County.

The ground covered by the lease of V. U. Rodgers and F. Fox on the San Bernardo mine, near Trout lake, near San Miguel, is reported showing satisfactorily. This summer they expect to make shipments. They have sublet a portion of the mine.

The Carribeau and Montezuma group of mines, 1 mile from Ophir, owned by Eastern men, as the Yellow Mountain M. Co., continues under development with thirty miners at work. By May 15th it is expected the property will be in shape to enable the production of sufficient ore to keep the company's concentrating plant running steadily, says Manager F. T. Axtell. Preparations are being made at the mill for beginning treatment of the ore. Additional machinery is going in, and plans for enlargement of the concentrating plant are under consideration. Concentrating tables will be put in. A water motor has been set in place for the utilization of surplus water for power purposes, which will reduce the cost of operating the plant. The mines and mill will give work to 100 men the coming summer.

Summit County.

The Lightburn tunnel of the Gold Run M. & M. Co., near Breckenridge, is working men in the main tunnel, in 2050 feet, and men are driving the hranch tunnel or crosscut ahead. It is in 1100 feet and is expected to cut a known lead-silver-gold ore vein when it reaches the 1500-foot point. Ventilation is maintained by air pipes from an electrically driven blower; the electricity is obtained from the Gold Pan plant at Breckenridge, 2¼ miles from the mine. These two tunnels are being driven to explore and develop a group of fifty lode claims which are owned hy Cripple Creek and Pennsylvania men. The group is on Mineral hill, near head of Gold Run.——Second-class or concentrating ore is being piled up on the dump of the Providence-Colorado M. & M. Co. awaiting milling facilities. First-class ore is in the ore hin ready for shipment. It is high grade in lead and carries gold and silver values. The drifts at 100 and 150 feet have shown up ore suitahle for concentration. H. S. Whitehead of Breckenridge is superintendent of the mine, which is on eastern slope of Gihson hill, near the Extension and Jumho groups.

The West Side (Engle) concentrating mill in Breckenridge, under lease to the Puzzle Leasing Co., after several months of idleness, has started up again, says Manager Hoyle, on ore from the Puzzle-Gold Dust strike.

Teller County.

At the Gold Coin mine at Victor, owned hy the Woods Investment Co., they have unwatered the 1100 and 1200 foot levels and have put men to work there. By unwatering these two lower levels the company will be ahle to get out ore from the Gold Coin vein, also the Little Montana dyke. The Gold Coin vein, when opened on the tenth level, or 1000-foot point, measured from 12 to 15 feet between walls and gave returns of from one to three ounces gold per ton. Besides these, there are a numher of other ore shoots that can be worked, says Manager Woods. The pumps are raising water at the rate of 500 gallons per minute.

On west side of Cow Mountain, near Gillet, a surface strike is reported made hy W. Mellon, showing a body of mineral 2 feet in width at grass roots. Assays range in value from $10 to $60. Mellon is preparing to sink a shaft 100 feet and start lateral work.——Work on the Clinton tunnel, on same hill, which starts at a point on southwest side, between the Spinney mill and the Short Line railway hridge, will he begun this week. The portal of the tunnel is 11 miles northeast of the Victor mine. The tunnel is expected to run in 3000 feet, gaining depth of 2000 feet at the terminus. The tunnel project is owned by the Clinton Con. M. Co., composed of Rochester, N. Y., men. A numher of veins and dikes of Bull hill trend in direction of Cow mountain. Some ore has been mined in the valley hetween the two hills and operations are in progress at several points.——F. Eakins, W. C. Ahhott and H. A. Raibling have a lease on a portion of the upper workings of the Wild Horse mine on Bull hill, owned hy the United M. Co. The terms of the lease include construction of a cyanide plant on the mine for treatment of all low-grade ores. The lease covers all the old workings of the Wild Horse mine from the 500-foot level to the surface, part of this ground having been explored below the fifth level. The lessees agree to perform 50 feet of work per month, either drifting or crosscutting, and further agree to huild a 50-ton cyanide plant. The royalties are graded from 30% to 50% (on all ores marketed that average above five ounces). The lease is for five years.

The leasing company operating on the Dexter mine on Bull hill, Cripple Creek, is sinking the main shaft to the 1000-foot point to recover the vein opened on the 900-foot level of the Blue Bird. Meanwhile the leasing company continues to send out occasional shipments from their workings from the 300 to the 500-foot point. They are screening and sorting the ore, the returns running two ounces gold per ton.

After an idleness of eight months, operations will be resumed next week on the Carbonate Queen mine of the Ophir G. M. Co., near Cripple Creek, says D. Sullivan of Denver, one of the company. Shipments were made last spring and summer. A depth of several hundred feet has been attained and levels run in several directions. C. Oliver is superintendent and also of the Dead Pine, owned hy the Ophir Co.

The Cripple Creek mill at Gillett will be ready for treatment of ore this week. The company will handle ore from the Bolivia, Belle Plain and King of Diamonds claims on Lincoln hill, and owned by the Lincoln G. M. & M. Co. This mill will treat fifty tons of ore per day.

IDAHO.

Cassia County.

The Shoshone Falls Power Co., Ltd., has been incorporated, with principal offices at Boise, to develop power at Shoshone Falls, on the Snake river, Twin Falls and Augur Falls. I. B. Perrine of Blue Lakes and R. M. McCollum, S. H. Hays, R. W. Faris and W. S. Bruce of Boise are directors. It is expected machinery for developing at least 20,000 H. P. will be put in.

Blaine County.

The mill at the Tiptop mines at Hailey, and owned hy J. Q. Packard, is ready for operations. It will use water pumped from the mines. The mill is of twenty stamps. The water used has heretofore been pumped from Rock creek, a vertical raise of 900 feet in a length of a mile. This station has been dismantled and the hoiler moved to the mine, where it will be used to keep the lower workings unwatered. The Tiptop mines show hodies of gold and copper hearing ores.

W. A. Stanton of Salt Lake City, Utah, manager of the Queen of the Hills mine, near Hailey, says he is preparing to resume in May. Additional machinery will he put in.——The flow of water tapped near tbe 1200-foot level of the Minnie Moore is under control, while at the Relief, an extension of the Minnie Moore, the management has opened up a body of milling ore on the 400-foot level.——The heavy snowfall iu the region is causing some uneasiness and, unless the thaw is anticipated and the hridges hy which the Wood river is spanned are strengthened, the installation of machinery on the other side will be delayed, says W. A. Stanton.

Boise County.

H. L. Fisher of Idaho City has an option on the Belshazzar group of gold-hearing quartz claims, 1½ miles southwest of the Gold Hill mine, at Quartzburg.

Custer County.

Owing to a breakage of machinery at the White Knob C. Co.'s mines, near Mackay, the smelter has been closed down for a month.

Elmore County.

The Tahoma mine, near Atlanta, is reported honded to Salt Lake City, Utah, parties for $200,000. The property has a mile of underground work on it, and is equipped with a 10-stamp mill, assay office, hunk houses and other buildings. S. J. Baldwin of Boise, manager, left to-day to make an examination of the mine for the Salt Lake people, to determine what work should be done this summer. He will probahly visit Salt Lake and Chicago before his return in the interests of the mine and its owners. When Mr. Baldwin was seen he refused to have anything to say regarding the deal further than to admit that he was going out to examine the property, and that such a deal as ahove mentioned had been made.

Shoshone County.

The Kellogg tunnel of the Bunker Hill & Sullivan mine at Wardner, in over 2 miles, is opening up the ore body uncovered in Nos. 7 and 8 tunnels. On No. 7, which is 500 feet above the Kellogg tunnel on the dip of the vein, the stope was 450 feet long and in one place 105 feet wide. This was at depth of over 2000 feet on dip of vein. The ore hody is cut in the Kellogg tunnel at depth of between 2600 and 3000 feet on dip of vein, which is at 45°. No. 7 is 250 feet above No. 8. The hody of ore is said to average 15% in lead and from seven to eight ounces in silver.

Electric power from Spokane falls, 100 miles distant, will he furnished to operate an additional 500 H. P. compressed air plant in the Morning mine at Mullan, Sept. 15. T. L. Greenough and P. Larson of Spokane, Wash., own the Morning. Three years ago a 1000 H. P. com-

pressed air plant, with 100-drill capacity, was put in at the Morning mine, said to be the largest compressed air plant in the West. The machinery has been working steadily since that time, but the output of the mine is increasing so that 500 H. P., with 50-drill capacity, will be added. It will be driven by an electric motor.

Washington County.

The Fidelity C. Co. of Portland, Or., reports Superintendent Trevor, has started operations at the company's property at Seven Devils, near Weiser. Ore will be taken out and shipped to the Ladd smelter at Mineral.

MICHIGAN.

Houghton County.

The annual report of the Isle Royale C. Co., near Houghton, for year ended Dec. 31, 1903, shows, compared with 1902:

	1903.	1902.
Gross value copper product....	$411,313	*$425,125
Running expenses at mine.....	307,437	400,539
Miscellaneous expenses.....	56,618	60,446
*3,134,601 pounds, at 13.12 cents.		
	1902.	1903.
Tons rock stamped.....	263,672	199,493
Pounds mineral obtained.....5,219,305		4,408,615
Percentage refined copper in mineral.....	68.374	71.102
Percentage refined copper per ton of rock stamped	13.5	15.7
Product fine copper (pounds)....3,560,748		3,134,601
Cost per pound at mine, exclusive of construction.....	11.23c.	9.81c.
Cost per pound construction.....	0.29c.	
Cost per pound exploration.....	0.24c.	0.23c.
Cost per pound of smelting, freights, Eastern express commissions and all other charges.	1.69c.	1.81c.
Total cost per pound of refined copper.....	13.45c.	11.85c.
Cost of mining and stamping per ton rock stamped	$1.25	$1.54
Cost of stamping per ton.....	26.44c.	28.84c.

President Bigelow says it had been hoped that with the openings tributary to No. 1 shaft, showing some improvement during the latter part of the year, better results would be obtained during the coming year. However, in the latter part of December the shaft was destroyed by fire, and they are at present simply mining enough rock from No. 2 shaft to keep one head busy at the mill. It has not yet been decided whether No. 1 shaft will be retimbered at present or not. As detailed in report of superintendent, explorations with diamond drill showed a copper-bearing lode in southern part of the property, which appeared to be an extension of the Isle Royale lode. It is intention in the spring to locate this lode on the surface and do work upon it, and on the result of this exploration will depend largely whether they at once retimber No. 1 shaft, or decide to spend the money in opening at the new exploration.

The Champion mine at Painesdale is preparing to put in a gyratory crusher, said to be the first in the Lake copper section.

Sinking in No. 8, or the Mesnard, shaft of the Quincy mine at Hancock has reached a depth of 2700 feet, says the News. Drifts are being extended north from No. 6 shaft of the Quincy mine under the workings of the Franklin. It is expected the upper drift will reach the line of No. 8 shaft about the same time that sinking reaches that level. The management expects to have the Mesnard connected with the old workings by March, 1905, when much of the rock that is now hoisted through the northern shaft will be handled to greater advantage through No. 8. Fully 50% of the tramming in the mine is being done by electric haulage.

Keweenaw County.

The Mohawk M. Co., operating near Allouez, reports for year ended Dec. 31 last, sales of copper (6,284,327 pounds at 13.11 cents), $823,941; sales of mohawkite, $14,467; working expenses at mine, $474,503; smelting, freight and cost of marketing copper, $69,680; general expenses, $7966; total expenses, $552,149. There was $218,076 expended in additions to plant and for new machinery. The balance sheet of the company of Dec. 31 shows, among other items, cash on hand, $25,103; copper on hand and copper bills, $180,860; cash and supplies at mine, $75,321. The mine began regular production in June, 1903, with two heads of stamps, and not until the latter part of Feb., 1904, did the third head go into commission. In regard to sales of "mohawkite," the report says the cross fissures carrying it have gradually become barren, and work has been discontinued on them. The company has united with other companies, allied in management, in erecting smelting works, which will go into operation about July 1. The rock in 1903 yielded 1.09% in copper, or 21.79 pounds to the ton, and it cost 8.78 cents a pound to get it out of the mine and to the market, and, including construction, the cost was 11.02 cents.

Ontonagon County.

The Victoria C. Co.'s mill at Victoria will have two heads and a new arrangement of rock crushers and grinders, which will send the rock under the heads crushed finer than at most of the mines in the district, says the News. The heads and machinery are worked by compressed air.

Rock from the Michigan mine at Rockland is averaging 40 pounds of mineral copper per ton stamped. Shipments to the Mass mill, where one head is used, average 235 tons daily, but it is planned to increase shipments until the head is treating its full quota of 500 tons.

MISSOURI.

Jasper County.

The Prime Concentrating Co. of Carthage has been incorporated by M. H. Teel and K. Birkbead of Wobb City, and J. G. Kirksey and H. L. Shannon of Carthage. The company is equipping a plant at Joplin to operate as a sludge mill.

H. Murray of Nashville, Ill., interested in the Joplin-Kentucky M. Co., owning a mine and mill on the John Jackson ground, west of Joplin, says he is arranging to resume operations. The mill has been idle for a year. The plant has been overhauled.

The Conqueror Z. M. Co. has started its new mill on the Cardinal mine at Midway. The mill has capacity of 150 tons and is equipped with automatic feed. The company has two shafts down to ore and a third one is being sunk. W. Houk is manager.

At Webb City an Iowa company has taken an interest with Prince & Co. on the Porto Rico mine and they expect to put up a mill. —— The Little Hoosier (heretofore the Ashcraft) mill, north of Webb City, is being torn down and rebuilt.

The Thoroughbred M. Co. of Joplin has been incorporated by F. Nicholson, B. H. Collins, J. W. Trick and C. W. Nicholson of Joplin and T. C. Jones of Webb City. ——G. A. Noel and L. Lands of Webb City have subleased eight lots on the lease of the Carthage L. & Z. M. Co. of the Palmer land at Kendricktown. They are under contract to put down a 5x7-foot shaft, put in pumps, etc., and operate the mine.

The Alliance M. Co., composed of C. Moore, A. Corbin, L. J. Stevison and Eastern men, has a lease on the Mussellmann land, west of the Mattes & Booker lease and south of the Ruby mine, on the High Ball lease, near Joplin. A shaft sunk on a drill hole strike is down 112 feet, with ore struck 5 feet above where the drill showed ore.——Negotiations are under way to consolidate all the interests of the Center Valley M. Co. under one management and reopen the idle properties. Pumps will be started and the ground opened for mining.

A mill is being built for the Prairie State M. Co., operating on the Continental Zinc Co.'s ground, in the west part of Joplin, says Superintendent Morsman.

Lawrence County.

The United Zinc Co. will let contract this month for sinking a deep shaft on the Expansion lease at Aurora, the intention being to tap the body of jack that has been developed by several drill holes.

Newton County.

The United Zinc Co. is completing a mill at one of its mines 2½ miles from Diamond, southeast of Joplin and 1½ mile south of the Jasper county line. The mill will be started up this week.

The Mascot mine resumed work last week after an idleness of several months, but did little on account of water shortage. The Mascot mill will be furnished dirt from the 125-foot level, which is said to be similar to that taken out at the 226-foot level and handled by the Homestake mill.

MONTANA.

The receipts for month of February of the United States assay office in Helena show a decrease of $38,864.19 compared to the receipts of same month in 1903. The greater part of this decrease is in Montana, although Washington, Idaho, Nevada and British Columbia all show a falling off. The total receipts of the office during the month were $137,563.36, divided as follows:

Counties.	1903.	1904.
Deer Lodge.....	$ 5 768 00	$ 6,287 88
Fergus.....	74,612 92	59,650 57
Lewis and Clarke.....	28,955 68	9,436 74
Madison.....	10,583 93	16,856 56
Park.....	10,518 20	13,718 90
Other counties.....	765 23	4,073 02
Idaho.....	7,730 51	2,915 80
Nevada.....	5,577 92	5 537 57
Washington.....	6,347 34	1,079 11
British Columbia	20,567 72	18,008 21
Totals.....	$171,427 55	$137,563 36
Totals for Montana	131,203 96	110,022 67

The Fergus county decrease was due to inability to send out the bullion from Lewiston, owing to irregularities in transportation of mail and express. The output was up to the standard.

Deer Lodge County.

Reports show work and developments progressing at Georgetown and vicinity, near Anaconda. The Gold Coin mine is under management of J. R. Boardman. Two of the mines are shipping ore to the Washoe smelter and more expect shipments before July 1st.

Fergus County.

The Mammoth Group G. M. Co. has resumed work on its mines north of the Gold Reef mines, near Gilt Edge. The Mammoth Co. is preparing to increase development. The first work to be done will be driving a tunnel from the mill level to tap an ore body shown in the workings on the hill above the mill, says the Argus. N. J. Littlejohn, of Lewistown, is superintendent. Ten men are at work. The 50-ton mill on the group will not be started up till sufficient ore is blocked out.

Work has suspended temporarily on the mines of the Judith M. Co. at the mouth of Spotted Horse canyon.

N. J. Littlejohn, of Lewistown, has bonded of the Cave Group M. Co. the Cave mining claim, Cone Butte district, near Lewistown. The bond specifies he shall work continuously during life of agreemont and that 10% of all net mill or smelter returns shall be paid the company.

Jefferson County.

A. A. Pelletier of the Red Bird M. Co., near Basin, is putting in machinery for the three mines that company is operating. It consists of one 125 H. P. portable boiler, one 50 H. P. engine and a 35 H. P. boiler and engine, one complete electric light system, air compressors, air drills and pumps. It is intended to increase work and take out ore.

The Golden-Sunligbt group of mines, 5 miles northeast of Whitehall, has been sold to E. Ring of Butte. The Golden-Sunlight group consists of twenty patented claims, eigbt mill sites, water rights, the Hedley Homstead, as well as the concentrator and machinery which has been in use in the development of the mines. Five of these claims have been producers for five years, leasers having shipped $250,000 worth of ore from them. The ore is principally sulphide, carrying gold and silver, while a small amount of oxide ore is also found. The mill and concentrator will be remodeled. On account of the system of leasing, it has been impossible to systematically develop the ground, says Manager Ring. All these leases have expired and renewals refused.

Lewis and Clarke County.

The Liverpool mine in Lump gulch, near Helena, has been reopened after a suspension of several years. Silver ore running 200 ounces is reported struck in the new workings.

It is reported the Ox Bow Power Co., incorporated in South Dakota, proposes building a dam across the Missouri river, near Helena. Electricity will be generated and transmitted to the mines and plants of Helena, Butte, Anaconda and other points.

Madison County.

Underground work is suspended at the Revenue mine, near Pony, and work begun on construction of a mill.

Missoula County.

The Nebraska-Montana G. M. Co. has been incorporated, with headquarters in Missoula, by G. W. Buchanan, B. L. Terry, W. N. Albright of Alexandria, Neb., B. W. Pugh of Belvidere, Neb., and T. Holt of Missoula.

Silver Bow County.

Surface improvements at the Dutton mine, near Butte, have been completed and the steam hoist is in operation. The hoisting plant has capacity for depth of 500 feet. Superintendent Rockwell says he has unwatered the shaft and resumed sinking and taking out ore. The shaft is down 250 feet. The Dutton is owned by the Butte M. & S. Co., and is between the Pennsylvania and Glengary mines in Butte district.

NEVADA.

Esmeralda County.

B. I. Potter, who has bought the Wheeler tailings at Pine Grove, has set up cyanide tanks, and will begin working the material next week. He is putting in a pump and other machinery. There are several thousand tons of these tailings.

The Jumbo M. Co. of Goldfield has been organized under Arizona laws by C. D. and H. L. Taylor, G. A. Kernick, G. E. McClelland and J. McKane as directors, to develop a group of claims in Goldfield district, south of Tonopah.

R. Gundry, superintendent of the Montezuma mines, near Hawthorne, says the company will begin work on a larger scale and expects to start shipping bullion.

Humboldt County.

The Glasgow & Western Exploration Co. is putting in two electrical ore separators at the company's Adelaide mill, near Golconda, says Manager Stalmann. Meanwhile the smelter at Golconda is being prepared for an early start.

Lincoln County.

The Caliente G. M. Co. has resumed work on the Sunset claim, near De Lamar, with G. C. Fetterman in charge. It is intended to drive a tunnel 200 feet from a point below the vein cropping to cut the ledge at depth of 150 feet.——Reports from Fay show work progressing. At the Horseshoe the mill is running eight hours per day, and with coming of spring the mill will be running twelve hours per day. Negotiations are in progress for buying water at Pike's Diggings, which will give about twice as much as the company has at present and enable the mill to work continuously.——Men are at work on the Snowflake group, owned by G. P. Smith.——The Homestake mill at Deer Lodge is running steadily. The ore is yielding satisfactory values, says Superintendent Hackett.——In the Iris mine, near De Lamar, enough ore has been opened to justify building a mill, says G. H. Smith, who is working the property on an option.

The shaft of the Pioche-Nevada M. Co., near Pioche, has cut 6 feet of galena-bearing ore, with sulphide of silver.

A. D. Cattle, manager of the New York Con. M. Co., with I. C. Stump and M. S. Briggs of New York, owning the Marie group, 6 miles north of Camp Duncan and adjoining the Capitol group of Monaghan & Murphy Co., near Searchlight, says they have started development work.

Nye County.

Forty-five miles of the Tonopah railroad are reported to have been graded and track laying is in progress. At present rate it is said trains will be running into the camp by May 15.

Washoe County.

At Olinghouse all four mills are running and the plates are showing amalgam. In the Butte & Gold Center mine they have opened the drift to the north in the lower level and have free gold values. W. C. Williams is milling ore from the Cabin claim and Gold Ledge, running $20 per ton.——W. W. Woodruff reports improved conditions at the Polar Star and Gold Treasury and says he has cut the lode which passes through the camp from the Whale to Gold Treasury.——At the Forlorn Hope 4 feet of a low-grade ore is opened at a depth of 35 feet in south shaft. Work has begun on the Crown Point.——The Springfield-Nevada M. Co. has prepared to increase impounding facilities at each mill and is beginning improvements with regard to handling of ore from mine to mill.

NEW MEXICO.

Lincoln County.

The Montezuma M. Co. is increasing its holdings of gold properties at Nogal.

Otero County.

Manager F. B. Schermerhorn says a smelter will be built at the Three Bears mine near Jarilla.

The Altamont M. Co. expects to resume work on its mines in Jarilla camp this month.

Sierra County.

Preliminary work has begun on the Good Hope and Bonanza mines near Hillsboro. A road is being built to the group.

It is reported Manager R. H. Hopper of the Bigelow G. & C. M. Co., developing a group of mines near Hillsboro, is preparing to put in additional machinery.

Socorro County.

A strike of copper ore is reported from Estey City. The ore body is 30 feet in width. Preparations have been begun for development.

L. M. Lasley, manager of the Golden Bell M. Co., operating at San Marcial, says he proposes putting in additional machinery for development work.

Taos County.

The Jayhawk G. M. & M. Co. has started sinking a shaft on its 6-foot lead at Red River. About 60 feet will be sunk and then crosscuts will be run before taking out ore for the mill.——Work will be resumed on the Midnight mine at Red River. The mine is at Midnight, at head of Bitter creek. The company has a concentrating plant and a steam hoist. The shaft is 165 feet deep, and crosscuts amounting to 6000 feet have been driven. The ore is free milling. The company is owned by Cleveland, O., men.——The Cashier mine, near Red River, will resume work and is preparing to patent four of its claims.

Platinum is reported found in Bromide district, near Tres Piedras, in the Tampa mine of the Tusas Peak M. Co., owned by Manistee, Mich., parties. It was found at the 200-foot level. The ore, in addition to 13% copper, $8 gold and $6 silver, is said to carry $26 in platinum.

OREGON.

Baker County.

The Virginia 10-stamp mill, near Sumpter, is in operation.——Van Duyn and G. Harklerood have bonded the Lone Pine

placer group of mine claims in Granite district. Preliminary work will be instituted this week and preparations for piping will be made. —— Babbington & Clark, who have leased the Bear Gulch placers near Sumpter, have started operations. The ditch has been connected with piping and a giant.

A sinking plant will be put in at the Snow Creek mine, near Sumpter, says Manager F. D. Smith. The plant will he for proving the ore shoot explored on the adit level at greater depth. Operations at the Snow Creek mine have been steady during the winter, with the full ten stamps dropping in the mill.

Grant County.

Placering will be started at the Black Butte group, near Granite, says Manager O. C. Wright of Sumpter. Superintendent E. C. Allen has made arrangements for starting work. The equipment to be used consists of two giants. Manager Wright states arrangements have been completed for adding to the water supply so as to operate all summer. That a still greater head of water may he secured for the placers, the management has outlined a system of storage reservoirs for the basin of the stream and will take up work constructing these before next winter. Operations at the quartz mines of the company have been as usual. Further development has been done on the vein, which shows width of 12 feet.

The Blue Channel Placer M. Co., operating near Susanville, has increased its machinery equipment. It has two giants and 2000 feet of piping, as well as a boiler for running a hoist to raise gravel from underground drifts.

Josephine County.

C. E. Woodrow has bonded the Ada mine, on Foots creek, near Grants Pass, which will be developed and later equipped with a mill and power plant.

SOUTH DAKOTA.

Custer County.

L. P. Woodbury of Chicago, Ill., president of the Saginaw G. M. Co., says operations will be resumed on the Saginaw mine, 6 miles northwest of Custer, on the forks of French creek. After the water is pumped out the company will run a crosscut to cut the three veins which run through the Saginaw claim proper at a depth of 200 feet.

Lawrence County.

The shaft of the Oro Hondo M. Co., near Kirk station, on the Burlington railroad, along Whitewood creek, near Deadwood, is 835 feet deep and sinking continues. It is intended to go to depth of 1000 feet before making any lateral explorations. At depth of 1000 feet a crosscut will be driven east and west on the formation. The bottom of the shaft is showing quartz ore bearing gold. The Oro Hondo is sinking a triple compartment shaft. The machinery is capable of depth of 2000 feet. There is in the Oro Hondo tract an area of 1000 acres.

The Pluma M. Co. at Pluma station, on the Burlington road uear Lead, will add forty stamps to its 40-stamp mill. They will make other changes about the mill.

Penuington County.

The Harrow & Williams graphite mine, near Oreville, will have an exhibit at the St. Louis Exposition. The vein is said to he 8 feet in width and the graphite high grade. The mine is near the Burlington railroad.

F. H. Long of Chicago, Ill., president of the Bullion M. Co., operating near Keystone, says he is preparing to increase development.

UTAH.

Beaver County.

Contracts for material with which to construct the first 800-ton unit of its concentrator at Newhouse, near Frisco, that shall ultimately be equipped for reduction of 4000 tons daily, have been awarded by the management of the Newhouse M. & S. Co., says S. Newhouse, president.

Manager Farnsworth, of Salt Lake City, of the Horn Silver mine at Frisco, says a plant will be built by the company to handle its zinc-bearing ores. He says in addition to 40% zinc contained in the ores, is an average of 9% lead, with some values in silver and gold.

The Beaver-Harrison M. Co. has heen incorporated to operate a group of mines in Beaver Lake mining district by J. J. Trenam, F. Eherhardt, B. L. Corum and E. H. Jacobs of Salt Lake City. The company has consolidated the holdings in the Beaver Con. and the Ben Harrison groups.

Juab County.

The consolidation of the Raymond and Illinois mines at Tintic, near Eureka, has heen ratified hy the shareholders. On the Illinois group a shaft has been sunk to 600 feet, with some drifting off it, while Raymond ground has heen opened to depth of 1500 feet, with five levels extended from it. The policy of the united interests is to drift in each direction on the 1500-foot level, says Manager J. C. Sullivan of the Raymond.

Six leasers are at work in the South Swansea mine at Silver, near Eureka, and ore is being shipped. The mine can be worked down to the 750-foot level, but below that water has filled the underground workings.

Millard County.

The Pluto M. Co. has been incorporated at Richfield hy S. F. Mount, D. and J. Meteer and K. and L. Mount. Twenty-seven claims comprise the holdings of the company in Millard county, 5 miles west of Scipio. Two shafts show a 2-foot ledge of ore that carries lead values in galena.

Piute County.

The Standard Power Co. has been incorporated at Salt Lake City to build an electric power plant on the Sevier river, near Marysvale, of from 4000 to 5000 H. P. capacity, and to deliver the electric power generated to the mining camps of Piute, Beaver and Sevier counties, as well as to cities and towns. W. F. Snyder, J. B. Weimer, F. Worthing and J. Long, Jr., are officers. The cost of generating power by steam is said to be from $20 to $25 per H. P. ner month, and the Standard Power Co. proposes to furnish electricity at not to exceed $7 per H. P.

Salt Lake County.

The Utah C. Co.'s new mill at Bingham is producing fifteen tons of high-grade concentrates daily, says the Reporter, and this product will begin to reach the market this week. The management of the American S. & R. Co. has contracted with the Utah C. Co. for its copper, gold and silver-bearing output from the concentrator. The contract comprehends the entire output of the Utah C. Co. for seven and one-half years, and provides for delivery within that period of approximately 35,000,000 pounds of copper, without reference to the gold and silver associated with that metal.

The Golden Spike M. M. & S. Co. has been incorporated at Salt Lake City to develop property in Big Cottonwood district, near Alta. The officers are G. Perry, P. Sibley, W. C. Tracy, T. W. Miller and C. Thorp, Jr.

The concentrator to be built at the Columbus Con. mine at Alta will have capacity of 150 tons per day, instead of less as first supposed, says T. Jacobson of Salt Lake City, president and manager. Construction will begin this month.

Machinery for the Bingham & New England mill, including a crusher, rolls and two-compartment jigs, is being set up at the Nast mine, near Bingham. The engine and other parts are on the ground and the mill is expected to be ready to run about April 18th.

W. Ochs, of Salt Lake City, has an option on the Davis-Gebhard group of copper mines at Bingham. The group, which embraces 141 acres of ground, is covered hy Government patent.

The Bingham Con. C. Co. at Bingham will begin construction by April 15 of a sampler at its smelter. The sampler will have capacity of 1000 tons of ore daily. The smelter is reducing 500 tons of ore daily with three furnaces in blast. In addition to output of its own mines, the smelter is reducing the tonnage from the Grand Central and Lower Mammoth of Tintic and the Boston Con. of Bingham, in addition to consignments acquired in open market, and by April 15 the management of the Fortuna of Bingham will begin forwarding to the Bingham Con., under a contract providing for treatment of 3000 tons monthly.

Tooele County.

The hoist at the Carisa mine at Robinson has been closed down and the leasers are working through the tunnel.

Operations have been resumed in the Old Bullion mine at Stockton under management of E. J. Dair.

T. Wiswall of Salt Lake City, manager of the Green Reduction Co., says the leaching of gold from the Geyser-Marion tailings dump at Mercur will he resumed this month, to continue steadily throughout the season. Concerning a similar undertaking at Mammoth, where the tailings from the Mammoth mill are to he handled hy his company, Wiswall says he is ready to begin building a plant as soon as the management of the mines has signed the contract.

WASHINGTON.

King County.

G. Daines of the Daines M. & M. Co. at Greenhorn, Or., and president of the Sure Thing G. & C. M. & S. Co., operating near North Bend, on the Snoqualmie river, says machinery for a 20-stamp mill is on the ground at the Suro Thing, and is being set up.

Whatcom County.

The Nooksack M. Co. of Seattle is preparing to put in machinery on its mine on Sumas mountain, near Bellingham, says Treasurer Swinehart of the company. A cyanide plant will be built to treat 200 tons of ore daily. A stamp mill plant to handle 200 tons of ore daily will also go in this spring. The buildings are all ready.

WYOMING.

Carbon County.

The Rudefeha M. Co. of Indianapolis, Ind., operating at Rudefeha, will put in a plant of machinery on the Udeville shaft as soon as spring opens, and development will he increased. The plant will consist of boiler, pump, hoist, compressor and air drills.

Fremont County.

An ore shoot has been opened in the Carissa mine at South Pass at depth of 400 feet. The owners will increase development, putting on more men, and whether the Belgo-American builds to South Pass or not, the Carissa will resume shipments of gold.

FOREIGN.

AFRICA.

Transvaal.

The Transvaal Chamber of Mines reports the gold output for month of Februrary of mines on the Witwatersrand was 282,436 ounces, and for outside mines 7066 ounces, making total of 289,502 ounces, as against total of 288,824 ounces for January. The Chamber also reports:

Natives distributed to mines during Februrary by Native Labor Association	6,263
Time-expired and other wastage	5,064
Net gain during February	1,199
Total number employed end of February	69,966

An allotment of 223 natives was made to railways, otherwise there would have been a gain in number for February of 1422.

AUSTRALIA.

New South Wales.

The New South Wales gold yield for month of February is reported amounting to 31,363 ounces, valued at £110,159, compared with 12,075 ounces, valued at £44,993 for February, 1903. The yield for first two months of 1904 amounted to 71,407 ounces, as compared with 32,386 ounces in January and February, 1903.

Qneensland.

The Queensland gold production for 1903 is detailed by the Under Secretary for Mines as follows:

Field.	1903. Stone treated at Mills.	Product. Mill Gold.	Cyanide Gold.	Gold from concentrates.	Old Tailings.		Treated at Metallurgical Works.		Alluvial.	Total Fine Gold from all sources

* Product from copper and other ores.

The total from all sources, of 668,546 fine ounces of gold, is against a total of 640,463 fine ounces for 1902.

Victoria.

The gold yield of Victoria for first two months of the current year is given at 117,540 ounces.

BRITISH COLUMBIA.

Bonndary District.

The numher of men at work in Boundary mines is heing increased. The Elkhorn has added a few men and the Providence also, making sixty men at these two properties. Both are shipping ore, say Phœnix reports. Next month new work will he started at the Oro Denoro, Summit camp, which will result in shipments heing increased to 250 tons daily. Present rate is 150 tons per day. It is reported a find of ore has been made in the Emma mine, Summit camp, adjoining the Oro Denoro. It was opened in the tunnel, started below the original quarries. J. J. Campbell, of Nelson, is manager.——Last week the first of the lot of 10-ton mine cars for use in the Granby properties were put in. They are of steel and will be used in the No. 1 and No. 2 tunnels, where the small locomotives are utilized.——The Spokane Boundary M. Co. has been organized in Spokane, Wash., to take over the Last Chance group of high-grade claims, 2 miles below Phœnix. The property is equipped with machinery and has been a shipper.—— Horses are being used at the 300-foot level of the Old Ironsides mine for hauling ore cars. When the No. 4 tunnel is connected with that level, in the course of two or three months, the horses will be taken out that way.

Cassiar District.

H. H. Jones of Victoria, manager of the Rosella Hydraulic M. Co., states that the company's representative in the section of the province, next the Yukon boundary, reports the Indians have disclosed existence of petroleum seepages. The new fields are in the angle formed by the British Columbia boundary line with that of Athahasca and Yukon Territory.

East Kootenay District.

J. P. Larsen, owner of the Tiger-Poorman group of claims, on the divide between Sheep creek and the North Fork of Wild Horse creek, near Fort Steele, is preparing to work his mines. As there is ore on the dump, Larsen proposes building a wagon road down Sheep creek to the Golden and Fort Steele road and will make shipments.——A. Macleod will start work on the Approach claim, 2 miles from Fort Steele. It is a silver-lead proposition.

Rossland District.

After three months of working test of the Elmore oil process of concentration at Le Roi No. 2 mine at Rossland, H. H. Claudet, manager for the Elmore Co. at Rossland, says the average of the low-grade ore from Le Roi No. 2 is $5 a ton in gold, silver and copper. This ore is crushed in the Chilean mills, seut through a 40-mesh screen, and then the pulp passes over tahle concentrators, where $2.50 per ton is taken out. The tahle tailings are then sent to the oil plant, where an oil concentrate running $45 is produced for shipment to the smelter. That is equivalent to an extraction of 75% or 80% of the metal in the ore, and the oil process gets 55% to 60% of the values in the tailings. The plant is of 50 tons capacity, while a 100-ton plant could he run with the same numher of men, says Claudet. There have been shutdowns because of lack of oil. The loss of oil in the process is about one gallon of oil for each ton of ore treated. The cost was $2.40 per ton for the first month's treatment. It is expected to do better than that with experience and a larger plant, and the cost will be about $1.25 per ton. The Canadian duty on crude oil having been rescinded, larger and cheaper supplies of oil will he obtained from the United States. A contract has been closed for a 100-ton plant for the White Bear mine at Rossland.

West Kootenay District.

Work will be increased on the Goldfinch

mine, near Camborne, this summer, says A. F. Rosenberger, manager. —— The third monthly cleanup of the Oyster 10-stamp mill resulted in a 300-ounce gold bar of the value of $4700. The mill was in operation 700 hours and 1160 tons of rock were treated. —— The Nettie L. and Silver Cup mines at Ferguson will resume operations and take out ore about May 1st. The reduction plant is nearing completion.

W. B. Pool and J. J. Young of Nelson, part owners of the Great Northern M., Ltd., are arranging to put in ten additional stamps with other equipment for the Oyster-Criterion mill at Camborne. The mill has ten stamps, three Frue vanners, compressor plant, waterwheels and other machinery. The mill is connected with the mine by an aerial tramway. Pool & Young are also arranging for a 40-stamp mill for reduction of the ores from their Lucky Jack and Swede groups in Poplar Creek camp. The tunnel on the Lucky Jack load has been driven in 320 feet. The breast of the tunnel has a vertical depth of 175 feet. Explorations on the Swede group have shown ore. There are fifteen leads on the two groups and all carry payable ore, says Pool.

MALAY PENINSULA.

The Government Gazette gives the following tin output for the Federated Malay States for year 1903:

State.	Tin. Pikuls.	Tin Ore.† Pikuls.	Total. Pikuls.	Duty.
Perak	162,634.82	273,435.80	436,370.62	$5,057,412.82
Selangor	133,384.32	150,890.57	292,654.80	3,364,300.00
Negri Sembilan.	43,008.21	142,488.85	85,497.07	987,005.40
Pahang.....	6,161.30	10,114.07	25,275.37	174,101.96
Totals	345,488.55	491,310.29	839,807.84	$9,582,270.07

Pikuls 128.31 wolfram were exported from Batang Padang, duty collected $32.37.

† Includes pikuls 32.37 wolfram, duty collected $32.37.

‡ Includes $30.11 duty on pikuls 28.18 tin slag.

In Pahang duty was collected on 65% of the gross weight of tin ore up to June, 1903, and from July, 1903, on 68%, and in some special cases on 65% of the gross weight.

The 1902 output was: Pikuls 335,692.80 tin and pikuls 445,998.00 of tin ore. The pikul (spelled also, pecul) is equal to 133.33 pounds.

Singapore reports say the crushing for four weeks ending March 1, by the Raub G. Co., Ltd., yielded 1100 ounces gold from 2600 tons ore.

MEXICO.

Chihuahua.

B. Davis, manager of the Corralitos L. & C. Co., of northwestern Chihuahua, together with Alamogordo and Eastern men, has organized a development company to exploit mines, timber and other resources in the Southwest, includign Chihuahua, as the North Mexican Dev. Co. B. Davis is president and D. C. Sutton, of San Pedro, Chih., is manager. The company owns the Adventurera and Santo Domingo mines, both silver-gold properties, in Sabinal district on the Sierra Madre railroad.

W. D. Pearce, manager of La Luz G. M. Co. at Maguarichic, is putting in two gasoline engines at the mines.——G. W. Boyce is putting in five gasoline engines for his several mining companies at Terrazas and Victorino.

H. E. Cary of New York, with Coleman & McKay, bought the Lluvia de Oro mine, near Urique. The mine is showing up satisfactorily. The 3-stamp mill is shut down for want of water, but machinery for the 20-stamp mill is being transported to the millsite near the mine. The difficulties about timber and water rights and a millsite have been settled.

G. W. Phillips, manager of the Calera zinc mine, near Minaca, says he has sold his interests in thirty pertenencias, near the Calera mine, to Couch, Meyer & Ellis for $12,000 Mexican. The Calera Co. will put up a reduction plant as soon as the railroad from El Carpio is built.

Grading for the mill of the Dolores mine, near Terrazas, is progressing, says Manager J. G. Hardy.

The Buena Ventura M. Co. is putting in machinery, including a hoisting plant, at its mines near Parral. J. W. Pender is manager.

Durango.

E. W. Hind says he is putting in machinery and a power plant at his group of mines at Gavilanes.

Jalisco.

The Guadalupe and La Bonanza mines have been sold to Whitney & Bruckner of Etzatlan, who will put in machinery and increase development.

A. L. Waters of Guadalajara, manager of the Keystone C. S. Co., operating near Tapalpa, says their machinery equipment will be increased.

Lower California.

The Joaquina G. M. Co. of Real del Castillo has its 10-stamp mill running steadily. The company has been developing its property for a year and a half and reports ore supplies blocked out.

Mexico.

The Aguila group in the Hostotipaquailla district has been bought by the Lawson Investment Co. of Boston, Mass. The property adjoins the Cinco gold and silver mine.

Sinaloa.

F. L. Roudebush says he has bought the Guadalupana mine and extensions at Rosario, adjoining the El Taje mines. He has secured the Bonanza and Providencia mines, the San Juan group and the San Marcus group, in the eastern part of the State of Sinaloa, near the Durango line.

Sonora.

J. E. Hubinger of New Haven, Conn., president of the Provedora C. M. Co., says the company will build a railroad from its mines 35 miles to Puerto Lobos, on the Gulf of California, and that construction work will begin this year. Hoisting machinery is being put in.

The Santa Rosa mine in Sonora, 16 miles south of Douglas, Ariz., owned by Douglas men, with T. E. Rendle as superintendent, will have a reduction plant. A 25 H. P. hoist and a 50 H. P. compressor will also be put in. A wagon road has been built from the mine to the Nacozari railroad, a distance of 4 miles. Two shafts have reached a depth of 200 feet and drifts are being run from the lowest levels.

Zacatecas.

B. C. Wheeler, formerly of Colorado, is operating a silver mine in La Norica district, near Sombrerete, under a lease and option. The bulk of the ore runs one kilogram (32.15 ounces Troy) of silver per ton. The ore is being treated by amalgamation, and a mill with a capacity of forty tons per day has been built at the mine. He is interested in the Vacas-San Marcos mines in Durango.

It is roported the San Rafael mine, near Zacatecas, will be unwatered and sinking resumed in the shaft.

PHILIPPINE ISLANDS.

G. P. Hernois, formerly of Butte, Mont., reports having located coppor deposits in the northern part of the island of Luzon, near Cervantes. He writes that since the cessation of hostilities in that section the country is being developed by American capital.

TASMANIA.

The Mount Lyell M. & R. Co., at Mount Lyell, reports, from February 4 to March 2 inclusive, a total quantity of 29,666 tons of ore was treated, being 22,106 tons from the Mount Lyell mine and 7560 tons from the North Mount Lyell mine. In addition to the above there were treated eighteen tons of purchased ore. The converters produced during same period 592 tons of blister copper containing: Copper, 584 tons; silver, 61,682 ounces; gold, 1480 ounces.

The Mount Zeehan Silver-Lead Co., at Mount Zeehan, reports February output at 435 tons of silver-lead ore, containing 240 tons of lead and 34,000 ounces of silver.

Personal.

E. Ring of Butte, Mont., is in New York on mining business.

Theodore Craig of Bouder, Colo., has returned there from Chicago.

R. B. Lindsay, a mining man of Denver, Colo., is in San Francisco, Cal.

R. M. Green of Oroville, Cal., is in San Francisco, Cal., on mining business.

G. W. Boyce of Chihuahua, Mexico, is in Boston, Mass., on mining business.

H. W. Turner of San Francisco, Cal., is examining mines at Tonopah, Nev.

Arthur Winslow, E. M., is in San Francisco, Cal., from Goldfields, Nev.

W. J. Morris now represents the Selby Smelting & Load Co., in Nevada county, Cal.

Jackson Dennis, a mine owner of Sutter Creek, Cal., is in San Francisco, Cal.

G. W. Phillips is manager of the Calera zinc mine, near Minaca, Chihuahua, Mex.

J. F. Judge of Salt Lake City, Utah, interested in Utah mines, is in San Francisco, Cal.

F. C. Ganter is superintendent of the Gold Coin mine, near Greenhorn, Baker ceunty, Or.

J. B. Farish, a mining engineer of Deuver, Colo., is in San Francisco, Cal., on business.

J. L. Bryson, recently manager of El Oro M. Co. at Maybert, Cal., is in San Francisco, Cal.

A. L. Gross, mine owner of Drytewn, Amador county, Cal., is in San Francisco, Cal., on business.

G. Daines, president of the Daines M. & M. Co., at Greenhorn, Or., is in the East on business.

H. Ballard of Mount Olivet, Sonoma county, Cal., is in San Francisco, Cal., on mining business.

W. A. Stanton of Salt Lake City, Utah, is at Hailey, Idaho, looking after mining interests.

G. H. Robinson of Salt Lake City, Utah, is visiting the Britannia mines in British Columbia.

J. Annear is superintendent of the Wood Mountain mine at Wall Street, Boulder county, Colo.

T. W. Davidson of the Oregon Development Co. is in the East on mining business from Sumpter, Or.

N. J. Brandett of Dawson, Yukon Territory, interested in Klondike mines, is in San Francisco, Cal.

N. B. Knox, E. M., has returned to San Francisco, Cal., from a professional trip to Inyo county, Cal.

J. F. Hendrickson is superintendent of the Lower Mammoth mine of Tintic district, near Eureka, Utah.

Jas. G. Hardy, E. M., superintendent of the Dolores mines, west of Chihuahua, Mex., is in San Francisco, Cal.

B. I. Potter has returned to Pine Grove, Esmeralda county, Nev., from San Francisco, Cal., on mining business.

F. T. Axtell is manager of the Carribeau and Montezuma mines at Ophir, Colo., of the Yellow Mountain M. Co.

Manager F. D. Smith, of the Snow Creek mine, returned to Sumpter, Or., last week from an extended trip East.

J. Knight of Salt Lake City, Utah, is manager of La Reine mines on Godiva hill, Tintic district, near Eureka, Utah.

J. A. McIntire of Sacramento, Cal., owner of the South Keystone mine, near Sutter Creek, Cal., is in San Francisco, Cal.

L. C. Shattuck of Bisbee, Ariz.. is manager of the Shattuck-Arizona C. Co., operating the Shattuck mines near Bisbee.

J. Ross, Jr., superintendent of the Lincoln-Wildman-Mahoney mines, near Sutter Creek, Cal., is in San Francisco, Cal.

W. A. Stanton of Salt Lake City, Utah, returned there last week from mines in which he is interested at Hailey, Idaho.

G. Kays, recently assayer of the Morning M. Co. at Mullan, Idaho, will represent the company at the Helena, Mont., smelter.

F. L. Bosqui is in San Francisco, Cal., from Goldfields, Nev., where he has been making cyaniding tests on the ore of that district.

H. De C. Richards, a mine superintendent of Orleans Bar, Siskiyou county, Cal.. is in San Francisco, Cal., on mining business.

Alfred Harvey of Denver, Colo, is erecting sampling works at the Guggenheim Exploration Co.'s plant, at Flat River, Mo.

J. L. Giroux, former manager of the United Verde C. Co. of Jerome, Ariz., has established his headquarters at Los Angeles, Cal.

R. H. Battey of Minneapolis, Minn., is president and manager of the Metropolitan G. & S. M. Co., operating near Ferguson, B. C.

J. I. Wright has been promoted from assistant to chief assayer of the Federal M. Co. at Wallace, in the Cœur d'Alene district, Idaho.

W. Zeigler, formerly superintendent of the Granite Mountain silver mine, is manager of the Ohio (Columbia) mine at Bingham, Utah.

The Fulton Engine Works, of Los Angeles, Cal., are placing a 5-stamp mill on the property of the Gold Pin M. Co., near Victor, Cal.

L. E. Aubury, State Mineralogist of California, has gone to St. Louis, Mo., from San Francisco, Cal., to install the California exhibit.

President T. S. Van Vleet of the Gold Bug M. Co. of Sumpter, Or., is in the East on mining business connected with his company.

G. C. Hazelett is general superintendent of a group of hydraulic properties in Nizina district, Alaska, with headquarters at Valdez, Alaska.

M. H. Lipman of Salt Lake City, Utah, president and manager of the Lipman M. & T. Co. at Hailey, Idaho, is in the East on company business.

D. Woodrum has resigned as assayer and chemist at the Bully Hill copper mines, De Lamar, Shasta ceunty, Cal., and is in San Francisce, Cal.

G. M. Nix, manager of the Oro Hondo M. Co., returned to Deadwood, S. D., last week, after an absence of several weeks, part of which were spent at Tonopah, Nev.

H. Murray, president and manager of the Gallatin Coal & Coke Co. at Nashville, Ill., has returned there from an examination of lead and zinc mining interests at Joplin, Mo.

Superintendent C. Oliver, of the Dead Pine mine of the Ophir G. M. Co., near Cripple Creek, Colo., has been given charge also of the Carbonate Queen mine of same company.

President J. E. Hubinger and Director F. D. Wetmore of the Provedora C. M. Co., operating in Sonora, Mex., returned to New Haven, Conn., last week from the mines.

A. B. Patterson, superintendent and manager of the Octo G. M. Co., returned to Baker City, Or., last week from attending annual meeting of the company at Wheeling, W. Va.

B. C. Cook of Deadwood, S. D., has been appointed superintendent of the gold reduction plant which the Black Hills section will have in operation at the St. Louis Exposition.

H. N. Cockrell of Spokane, Wash., has been appointed superintendent of the Washington mineral exhibit at the St. Louis Exposition, and will leave for St. Louis, Mo., this week.

N. J. Littlejohn of Lewistown, Mont., formerly superintendent of the Gold Reef mines, is superintendent of the Mammoth Group G. M. Co. in same district, near Gilt Edge, Mont.

P. A. Brady, superintendent of the Belcher and Red Lion mines near Granite, Or., returned there last week from an extended trip to New York, Montreal, Canada, and other Eastern cities.

F. A. Rankin, of Eugene, Or., interested in mining properties in Blue River and Bohemia districts and in the White Swan and California mines in eastern Oregon, has returned from a business trip to Portland, Or.

Thos. H. Leggett, E. M., left San Francisco, Cal., for London on the 29th ult. He intends to return next fall when he expects to direct large dredging operations in the interest of the Valero Syndicate, Ltd., of London.

O. N. Brown, superintendent of the Spearfish G. M. & R. Co., C. E. Heizer of the company's assay office, and M. Alber, master mechanic at the mill, returned to Lead, S. D., last week from a meeting of the board of directors in Colorado Springs, Colo.

Commercial Paragraphs.

The new offices of the Commercial Railway Equipment Co. are at 42 Broadway, New York City.

Jos. Ryan and Geo. Lynch have gone to Australia as agents for the J. Geo. Leyner Co. of Denver, Colo., to introduce the Leyner drill.

The Power & Mining Machinery Co. of Cudahy, Wis., have a contract for a new mill for the Cactus Co. at Salt Lake City, Utah, states their Denver agent.

The Crocker-Wheeler Co., through their Denver, Colo., branch, have recently sold two 65 K.W. generators to the Albuquerque Traction Co. of Albuquerque, N. M.

Delivery is being made to the Santa Fe of 100 new oil tank cars, each of 9500 gallons capacity. They are intended for the California oil fields. The Santa Fe now has between 800 and 900 of these cars. Even this large equipment is taxed at times to promptly care for the growing oil business in California and Texas.

Electric power from Spokane, Wash., will be furnished to operate an additional 500 H. P. compressed air plant in the Morning mine, 100 miles distant, this year. E. A. Rix of San Francisco, Cal., says: "Three years ago I put a 1000 H. P. compressed air plant, with 100-drill capacity, in the Morning mine. It is the largest compressed air plant in the West. The machinery has been working steadily since that time, but the output is increasing so fast that more

machinery is required to handle it. I have just finished an inspection of the works and shall immediately install a 500 H. P. compressed air plant with 50-drill capacity. It will be driven by a 500 H. P. electric motor operated by power from Spokane. The Washington Water Power Co. will furnish the power. It will be the largest electric plant in the West. It will be set up in addition to the present building of the plant at Mullan, Idaho. The contract calls for it to be in operation by September 15."

F. W. BRAUN & CO. of Los Angeles, Cal., propose to have a complete and interesting exhibit of goods of their manufacture at the St. Louis Exposition, to be held at St. Louis this summer, including all of their patented labor-saving devices for laboratory use, such as crushers, pulverizers, crucible and muffle furnaces, bullion melting furnaces, laboratory cyanide plants, gasoline, crude oil and illuminating gas burners, blowpipe outfits, etc. The display will be located near the southwest corner of the Mines and Metallurgical building.

Trade Treatises.

"Blasting by Electricity," from the Ætna Powder Co. of Chicago, Ill., describes in detail the operation of their blasting machines.

The S. S. Machinery Co., from their new home, 2464-2470 Larimer St., Denver, Colo., send illustrated description of various makes of machinery they are ready to supply.

The first edition Catalogue No. 5, from the Lake Shore Engine Works, Marquette, Mich., is devoted to hoisting engines and mining machinery, with notes and memoranda of practical value.

Bulletin No. 4 of the Jeffrey Manufacturing Co., Columbus, Ohio, protrays their makes of electric mine locomotives and other electric mining plant. Bulletin No. 5 shows similar economic device in storage battery industrial locomotives, with condensed technical information thereon.

The second edition of Catalogue 54, from the Allis-Chalmers Co., Chicago, Ill., brings out the salient points concerning the Sederholm boiler, going into the subject in minute detail. Technical tables in connection with the general subject of steam use add to the value of the brochure.

Books Received.

"Easy Lessons, or the Stepping Stone to Architecture" is the title of a little volume on the principles of architecture, by Thomas Mitchell. It is written in interrogatory style, consisting of questions and answers on the subject. The volume is profusely illustrated, and contains 92 pages of interesting reading. Price 50 cents, bound in cloth: The Industrial Publication Co., New York.

Latest Market Reports.

SAN FRANCISCO, April 1, 1904.

METALS.

SILVER.—Per oz., Troy: London, 25½d (standard ounce, 925 fine); New York, bar silver, 55½c, refined (1000 fine); San Francisco, 55½c; Mexican dollars, 45@46c San Francisco, 44c New York.

COPPER. — New York: Standard, $12.87½; Lake, 1 to 3 casks, $12.87½; Electrolytic, 1 to 3 casks, $12.87½; Casting, 1 to 3 casks, $12.75; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £58 spot per ton.

The copper market is firm, with prices unchanged. No heavy transactions in the metal are reported. The probability is that copper will be maintained at the present price for a time, as the stocks on hand, average consumption and production are generally known, and the outlook is hopeful. Buyers are placing no large orders and sellers are offering no inducements to change their attitude toward the market. Each seems satisfied to allow the existing conditions to continue for a time.

LEAD. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.85. London: £12 3s 9d ℔ long ton.

SPELTER.—New York, $5.25; St. Louis, $5.00; London, £22 ℔ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.00 @ 28.35; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 31c; less, 32c; bar tin, ℔ lb., 32½@35c. London, £127 15s spot.

PLATINUM. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75 @ 82c ℔ gram.

QUICKSILVER. — New York, $46.50@47.00, large lots; London, £8 7s 6d; San Francisco, local, $44@45 ℔ flask of 76½ lbs.; Denver, $48.00. Export, $42.00@42.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $13.85 @14.35; gray forge, $12.60; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ℔ lb.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl. .

CEMENT.—Imported, $2.15@2.40 ℔ bbl.; California carload lots, $2.00 f. o. b. at works; small lots, $2.25 ℔ bbl. in sacks, 4 sacks to bbl.

GENERAL SUPPLIES.

ANTIMONY. — New York, Cookson's, 7c; Hallett's, 6½c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8½c; 100-lb. lots, 10½c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE. –Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11½c ℔ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.20@1.40 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, French, 3½@3¾c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

BONE ASH.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.00; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 47c; cs., 52c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 20¼c; Astral, 20¼c; Star, 20¼c; Extra Star, 24¼c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb., 7c; less than 500 lbs., 7½c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

BISMUTH.—Subnitrate, ℔ lb., $2.00.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—$2.00 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., $1.00.

PHOSPHORUS.—American, ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING MARCH 22, 1904.

755,557. — CONVERTING MATTES — R. H. Aiken, Jerome, Ariz.

755,456.—WATER GAGE—W. Coger, Bisbee, Ariz.

755,361.—ELEVATOR—D. E. Condon, S. F.

755,459.—HARNESS—J. Cruthers, Naco, Ariz.

755,281.—TIME SWITCH—Dilhan & Mersanne, S. F.

755,118.—BEET PULLER—C. A. Dsyle, Los Angeles, Cal.

754,982.—HEATER—Jennie A. Edwards, S. F.

755,481.—ROTARY ENGINE—G. Griescbe, Berkeley, Cal.

755,483.—FRUIT CHUTE—A. Hamilton, Alhambra, Cal.

755,500.—UMBRELLA RIBS — J. O. Larrahee, Oakland, Cal.

755,506.—DIAPHRAGM—Z. J. Le Fevre, Los Gatos, Cal.

755,030.—SHOE LACE FASTENER—C. F. Miers, Ager, Cal.

755,171.—FIRE BARRIER WALL—H. Root, S. F.

755,250.—ANIMAL LEADER — H. O. Selfert, Kings Valley, Or.

755,323.—WASHING MACHINE—L. W. Smith, Anacortes, Wash.

755,408.—COOLER—J. J. Stephenson, Winters, Cal.

755,587.—PLANE—W. Ulses, Los Angeles, Cal.

755,419 —WINDOW FRAME—T. F. Ware, Steamboat Springs, Nev.

755,340.—OIL BURNER — J. M. Younger, Oakland, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

UMBRELLA RIB CONNECTION. — No. 755,500. March 22, 1904. J. O. Larrabee, Oakland, Cal. This invention relates to the combination of umbrella ribs and independent removable tips and means for connecting the two so that any rib may be attached or detached from the top notch without disturbing other ribs.

ROTARY TURBINE ENGINE.—No. 755,481. March 22, 1904. G. Griescbe, Berkeley, Cal. This invention consists of a drum having spirally disposed grooves or passages extending around it from the center toward each end and means for admitting an elastic medium under pressure either to pass through the said spiral passages from the center outwardly to drive in one direction or from the ends toward the center to reverse the motion of the apparatus. In conjunction with this drum is a casing within which it is revoluble and valves so disposed as to admit the propelling medium either from the center or the ends and to exhaust it from the opposite ends of the passages from the point at which it is admitted. These spiral passages are peculiarly constructed so as to permit an expansible action of the medium and both direct and reactionary pressure to propel the drum.

YOU CAN HAVE A
CROSS OIL FILTER
ON 30 DAYS' TRIAL, FREE.

The Somerset Stone Crushing Co., Bernardsville, N. J., writes us that the CROSS OIL FILTER SAVES THEM 50% IN THE COST OF OIL.

Hundreds say the same, but we want you to test it for yourself.

WRITE US TO-DAY and we will send you the CROSS OIL FILTER on thirty days' trial. If unsatisfactory, return at our expense.

THE BURT MFG. CO.,
Largest Mfrs. Oil Filters in the World,
221 Main St., Akron, Ohio, U. S. A.
Supplied also by Oil Companies, Engine Builders and Power Contractors.

DELINQUENT SALE NOTICE.

EUREKA CONSOLIDATED DRIFT MINING Company.—Location of principal place of business, San Francisco, California; location of works Placer County, California.

Notice.—There are delinquent upon the following-described stock, on account of assessment (No. 39) levied on the 12th day of January, 1904, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares	Amt.
Dixon, G. W., Trustee	455	500	$2 50
Dixon, G. W., Trustee	456	500	2 50
Martin, Alex	260	100	50
Taylor, A. W.	651	189	94½

And in accordance with law, and an order from the Board of Directors, made on the 12th day of January, 1904, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the company, Room 3, 214 Pine street, San Francisco, California, on MONDAY, the 4th day of April, 1904, at the hour of 1 o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

CHAS. W. DIXON, Secretary pro tem.
Office—Room 3, 214 Pine street, San Francisco, California.

Capital Wanted

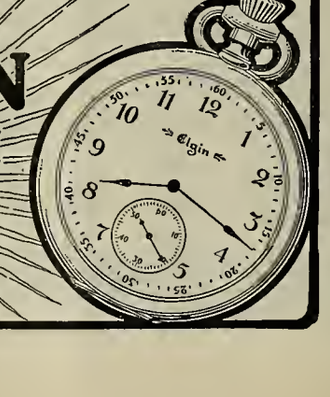
For the development of new Lead, Silver and Copper-Bearing Field, located in Coeur d'Alene Mining District, Idaho.

Plenty of timber. Money is desired to assist in locating leads, millsite, and take up water rights. For particulars, address

A. M. MUNDELL, Box 435, Wallace, Idaho.

A Place Well Won Beside the Sun

THE ELGIN WATCH



to-day regulates the world's time.

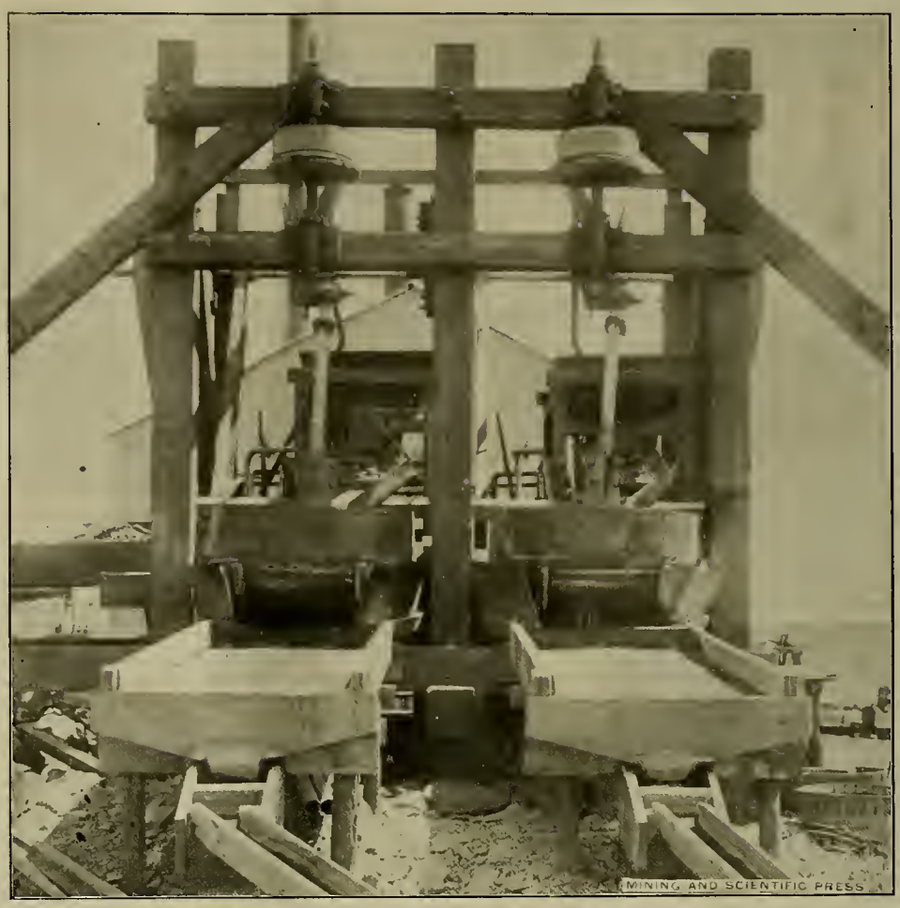
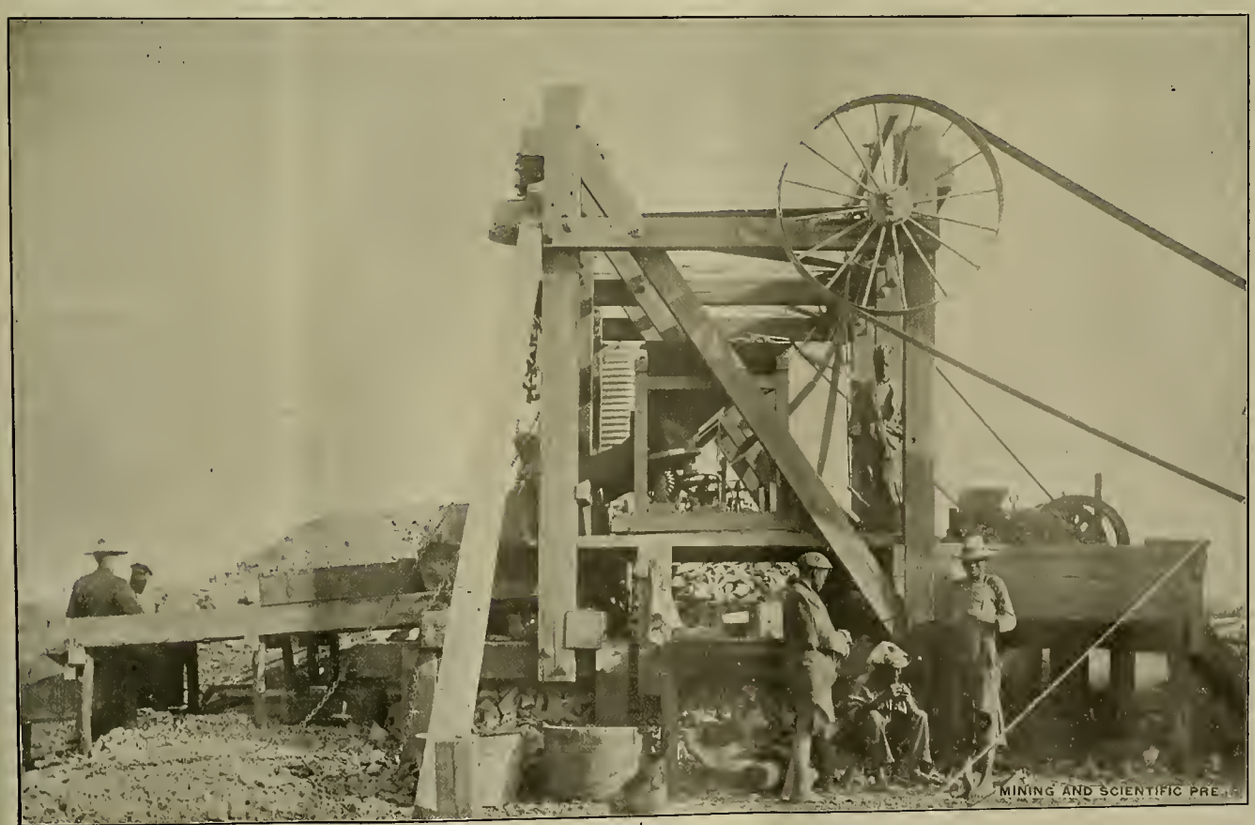
Cheap Labor vs. Expensive Construction.

It not infrequently occurs that the price of labor has an important bearing upon the methods of construction about mines, as well as upon the methods of operating a mine. Where wages are low, mining and construction methods are often permissible which under other conditions would be commercially impossible. Climate too often has an important bearing on these matters, particularly upon construction methods. The accompanying engravings illustrate a case in point. The scene is at Bulawayo, Rhodesia, South Africa, where two Kinkead mills have been set up by Fraser & Chalmers (Ltd.) of London, Eng., to grind the ore from one of the mines of that district. The mills are placed upon a substructure of heavy timbers to raise them to a sufficient height to secure the necessary grade. The ore feeder stands in the usual position, as related to the mills, but note the rock breaker which is placed a short distance above the feeder floor. All ore coming to the mill is shoveled out onto the breaker floor, fed to the breaker by hand or with a shovel, and the broken rock accumulating underneath the jaws is again shoveled onto an upper floor, and from there into the hopper of the feeder. In the United States such an arrangement would be charged to inexperienced tenderfoot management, but in South Africa the manager has a choice between cheap native labor and expensive timbers and construction, and in this case he has chosen the former. The negroes work for a few cents per day, and one might easily imagine, from their various attitudes, occupation and general appearance, that they were not discontented.



Front View of Quartz Mill at Bulawayo, South Africa.

The timber and lumber necessary to build the usual type of ore bins, with rock breaker at the top of the mill, would reach many thousands of feet (board measure), and as the freight charge alone, in addition to first cost, is about $120 per thousand, this makes mill construction very expensive in that region. The expense necessary to build the mill after the American idea, where all milling operations are performed by gravity, represents many hundred days of labor. While undoubtedly if the enterprise is an enduring one, and a large amount of ore is to be crushed, the proper mill construction would prove to be the most economical in the end, the present arrangement is doubtless a matter of expediency, and has been determined to be the best under existing conditions. In mining methods the same principles are often involved, and a system of mining is adopted which proves satisfactory and inexpensive in a country where the rate of wages is low; but, although this same system is readily applicable to mines elsewhere, the cost, due to the higher price of labor, renders it prohibitive. This is the case where ore is removed and filling placed by hand, by means of which method a wide vein of iron ore has been successfully mined in Spain; but the high cost of labor in the United States, even in those districts where labor is at the lowest, renders a method of this character impossible of adoption in this country.



A Quartz Mill in Rhodesia, South Africa.

Discrimination in Mine Reports.

In discussing descriptive reports of mines "on the market," it is sometimes said of the author: "His statements can be taken with much allowance—you must 'knock off' at least 50%, and then you are not safe." If this is a fact, the report is absolutely without value, as the coefficient of truthfulness is unknown, and it may as well be thrown aside. But if this man's report is unreliable, is that of he who samples the mine and reports values less than he actually finds any more entitled to absolute confidence than the former who magnifies them? Most veins and mineral deposits may be sampled with accuracy, by taking the necessary time and care. When this is done the actual assay results of these samples should be given, together with the width of each sample and a general description of the appearance of the vein and the physical conditions found at each place sampled. This makes a valuable report, whether the mine be good or bad. If good, the report is an indication of that fact. If poor, it is valuable information to know it. It seems as foolish and as unnecessary to understate as to exaggerate the values found in mine samples. The metallurgical problem is entirely separate and distinct from the sampling of the ore. Values which would indicate profit in one class of ore may be insufficient in another. Situation is another factor, as costs of mining and transportatiou may make a mine valueless for the time being, but these conditions may be changed by good roads or a railway. A mine which cannot be worked profitably through a shaft may be operated through an adit tunuel, as the expense of hoisting, ventilation and drainage are eliminated. It is not altogether the determining of the values of the ore and its amount that fixes the worth of the mine. Some years ago an elaborate report was issued descriptive of a copper property in which the statement was made that there were $11,000,000 in sight. A mining engineer was employed to investigate and he verified the report, but supplemented it with the statement that in his judgment about $13,000,000 would be required to get it out.

The Right Kind of Economy.

In all mining and metallurgical operations economy should be practiced. This is more essential in the operation of a low-grade mine or reduction plant than in one having rich ores. There are, however, two kinds of economy—that which is wisely directed and that which is short-sighted and parsimonious. The experienced manager, who must also be a good business man, does not hesitate to incur any expense in equipment or operating cost, when he can see that this expenditure will reduce the cost of production, whether it be gold, copper, iron or any other merchantable product, but the first cost, expense of maintenance and probable deterioration of any proposed investment or addition to plant should be carefully considered, and its relation to the probable output of the mine. If, for instance, a uew installation is proposed, the purpose of which will be to reduce operating cost, saving 50 cents per ton over the method in use, it should be demonstrated that the ore available will justify the expense of the change or addition to plaut. If it is known that only about 100,000 tons of ore remain, and the cost of the proposed change will reach $50,000, obviously there is no incentive to incur this new expense, for the miue exhausted, the plant remains on haud, and, if sold, will probably not pay the interest on the money invested in it. There are mines operating through small, poorly equipped shafts, where the annual expense of maintaining such shaft reaches $15,000 per annum, owing to the character of the ground through which the shaft has been sunk. There are several instances of this kind iu California, where shafts more than 1000 feet deep have been kept opeu for a decade or more at great cost, when, had a shaft been sunk in the hard wall rocks of the vein, the first cost would have come well within the aggregate expense of keeping the present shaft open during all of these years. A shaft once sunk in hard ground needs little repairs, and a far greater tonnage can be handled through it. The shafts sunk in the soft, swelling ground are constantly being forced out of line. Steel rails cannot be safely employed, and, as a result, the skips or buckets are run at comparatively slow speed. With a good, roomy shaft in hard ground, at least three times the amouut of ore, waste and other materials can be handled at practically the same expense; the mine can be worked more rapidly with a larger force underground, the top crew remaining about the same. Insurance, taxes, superinteudence, and many other expenses are no greater. When all of these things are considered, it makes the incidental expense much greater than the cost of merely keeping the old incline open. This neglect to sink a shaft in a suitable place is what may be termed parsimonious economy. It is not often the superintendent or manager is responsible for this condition of things; but the board of directors, who in their short-sightedness fail to realize the importance of properly equipping a mine. As opposed to this there are instances of extravagance in mining equipment which are equally bad. The equipment of a property with large and expensive hoisting plant to sink a prospect shaft, when it is not known auy rock of value will be discovered; the building of a large mill and construction of railroads to connect the mine and mill, before any ore has been developed, are among those of this class. Mine management requires careful, conservative and experienced men, those whose judgment may be depended upon to do the proper thing, and who are neither foolishly extravagant nor parsimonious. The saving of a few cents per ton often represents the difference between success and failure.

COPPER STATISTICS for 1903 recently issued show that the productiou for that year for the entire world was 589,361 tons, and the consumption during the same period 605,000 tons, an excess over production of 15,639 tons. This could ouly have been possible by utilizing a large portiou of the stock on hand at the end of 1902. In almost every country of the world where large amounts of copper are utilized annually the statistics show an increasingly greater amount going each year into electric construction. In Germany, for instance, it has risen from 29% of all the metal used in 1901 to 39% in 1903. Other uses show no great fluctuation in the amount consumed. It is a difficult matter to secure accurate information as to the existing copper condition. Copper, while not indestructible, is being returned to the market in the form of old metal more than any of the other base metals. This amouut varies with the price. When the price is high old copper is returned and turned out in new forms, and this metal forms no inconsiderable portion of the eutire amount annually going iuto the industries and arts.

The Alaska of To-day.

The northern papers are already reporting numerous aud rich finds in Alaska and the Northwest Territory, and the impression prevails that the movement to the Arctic region will be very large this spring. Unless new diggings, easily worked, are discovered, that section will not prove to be a good place for a man of limited means. The mineral resources of Alaska and the adjacent country are as yet little known, but sufficient has already been learned to indicate that, aside from a few exceptional spots, it is not the "poor man's country." What Alaska now needs is large capital to divert rivers, build ditches, flumes and pipe lines; construct dredgers, and to operate the mines on a large scale by modern methods. Railways and telegraph and telephone lines will follow. The mines must be opened first, to demonstrate that there is sufficient business to justify the large outlay of capital to afford these conveuiences of transportation and communication. Doubtless electric plants will also be installed to transmit power to mines and other industrial institutions. The Alaska of to-day is unlike the Alaska of early Klondike days, or even those of early Nome. The miuing methods familiar throughout the western United States have been introduced there and have been fouud as applicable to conditions in the far North as they are to Idaho, Montana, South Dakota, British Columbia or elsewhere in the Northwest. With the exception of a few important operations along the coast, vein mining has not yet been developed extensively in Alaska, but enough is already known to satisfy mining men and capitalists that that country will in the future produce a large amount of copper, coal, petroleum, and possibly also tin, as well as gold. The discovery of veins is difficult, owing to the moss and drift which covers a great portion of the country, and these difficulties are multiplied by the long winters and deep snows. Notwithstanding these drawbacks, the prospector has been at work and promising quartz discoveries have been made, the success of which will stimulate the search for others. Few people realize that the vast extent of territory covered by Alaska greater than the area of Washington, Oregon, California, Nevada and Idaho, and the indications are that the mountain ranges of this region are mineral bearing. It will be many years before the resources of the territory are developed or known.

THE Government in its suit against the Mountain Copper Co. of Shasta county, Cal., has instructed its attorney to withdraw the application for an injunction until the final hearing of the case on its merits, the copper company having agreed to pay the Government for the loss sustained. Any one familiar with the surroundings of Keswick would be surprised to learn that the forests thereabout had suffered damage from the sulphurous fumes. The timber was scattered and stunted at best before the copper company began operations there, and in the neighborhood of Keswick has mostly been cut long siuce for miniug aud other industrial or domestic uses. The general benefit to the community and State derived from the operation of the mines and smelters of the Mountain Copper Co. seems to far outweigh any damage which may have resulted to the forests of the reserve, and the expert testimony of men who are authority ou agricultural and horticultural matters determined long since that the damage to crops and fruit trees was much more than offset by the advautage of haviug the mines and smelters in operation.

CONCENTRATES.

SOLUBLE SILICATES are decomposed by hydrochloric acid, and if the solution be concentrated gelatinous silica forms.

THE mineral specimen from Silver Star, Mont., is a kaolinized quartz-bearing rock, probably granite or quartz porphyry.

BLACK FLUX, used in assaying, is a mixture of three parts flour and ten parts sodium-bicarbonate. It is employed in crucible assays.

THE small dark green mineral specimen from Grass Valley, Cal., supposed to be pitch blende, is serpentine, and contains no radium or other uranium minerals.

PITCHSTONE and pitchblende are not synonymous. Pitchstone is a volcanic glass, entirely free from phenocrysts and spherules. Pitchblende is an ore of uranium.

METACINNABARITE is an iron-black variety of mercury sulphide. It is similar in composition to cinnabar. It has a reddish-brown streak. Not a common mineral.

THE white metallic malleable metal obtained on burning the ore in the forge at Fenner, Cal., is probably metallic iron reduced from iron oxide or pyrite in the ore.

SILVER is readily tarnished by contact with sulphur or sulphurous fumes, but gold is not so affected. The so-called "oxidized silver" is really a tarnish of sulphide of silver.

THE occurrence of gold in limestone is not uncommon. There are numerous mines of this class in the Black Hills of South Dakota, and in Mono, Inyo and San Bernardino counties, California, as well as elsewhere.

STAMPS cannot be given a rapid drop with long-armed cams. The slow drop mills are provided with cams of large size, which lift the stamps from 16 to 18 inches, dropping them twenty-eight to thirty times per minute.

SOME telluride ores will show metallic gold on the surface when strongly heated, but the ore, to do this, should be rich and abundant. Finely disseminated telluride gold ore might fail to show the gold owing to the microscopic fineness of the globules.

THE best way to work a free milling gold and silver ore is by the pan process, in which bluestone, salt and mercury in the presence of heat supplied by steam are the principal factors. Silver sulphides and chlorides may be concentrated, but not readily.

THE magnetic attraction in mines is due to various causes. Track rails, iron and steel tools and machinery, and the rocks themselves in some mines, exert sufficient influence to deflect the magnetic needle, sometimes causing a variation of as much as 20° within a few feet.

THE following is given as a good flux for ordinary gold and silver ores: Dried borax, 1 pound; sodium carbonate, 1½ pound; cream of tartar (argol), ½ pound; white sugar, 1 ounce. This quantity will be sufficient for about ten charges where 25 grammes of ore are taken for assay.

THE mineral specimens from Prescott, Ariz., are: No. 1, specular iron (iron oxide): No. 2, epidote, probably due to alteration of hornblende: No. 3, tourmaline; No. 4, andesite, a volcanic rock; No. 5, quartz-porphyry; No. 6, quartz, with an incrustation of antimony sulphide (stibnite).

POLYBASITE is an antimonial silver ore—sulphur 15.0, antimony 9.4, silver 75.6. This ore is one of the complex ores of silver in which the antimony is sometimes replaced by arsenic and the silver by copper. It is iron black in color, the thin splinters cherry red. The luster is metallic.

TANKS made to hold the solution of iron sulphate, in chlorination works, should be made without nails or iron of any kind. The tank can be made by means of mortises and wedges to hold the boards tightly together. Iron is rapidly corroded by the acid and the tank would last but a short time if nailed.

A PERSON obtaining a mining concession in Mexico may dispose of the same to another in the United States, but the buyer must as soon as possible place the transaction on record in Mexico, and comply with the requirements of the Mexican mining laws which differs materially from those of the United States.

WULFENITE is molybdate of lead, occurring in tabular honey-yellow to orange-red crystals, transparent to opaque. It is found in Arizona, Nevada, New Mexico, Utah, southern California and Mexico, more abundantly than elsewhere in the United States. It often occurs in these regions with the ores of gold and silver, and prospectors are sometimes deceived when horning or panning their ores, mistaking the wulfenite for gold. It is soluble in hydrochloric acid. Wolframite is a heavy black ore, a tungstate of iron and manganese, and in no way resembling the ore above described.

GOLD is known to occur in serpentine and talc, but usually in extremely thin sheets, like the thinnest of gold leaf. These occurrences are mostly in the vicinity of a vein or fissured zone. Ore of this kind is irregular in the distribution of values and is also difficult to treat. Cyanidation by the decantation method is probably the most satisfactory way to treat such slimy ores.

SODIUM NITRATE (saltpeter) occurs abundantly near the border line of Chile and Peru, South America. It contains, beside the nitrate, sodium chloride, sulphate and iodate. Sodium nitrate is similar to potassium nitrate, but it cannot replace the latter in the manufacture of the finer grades of powder. The iodine occurring with the natural salt is now extracted separately.

THE Triassic age or formation usually consists of sandstones, shales and marls. The rocks of that age are distinguished by a red or reddish brown color. All red sandstones or shales, however, are not of Triassic age. The only minerals known to Concentrates to occur in these Triassic rocks are copper ores in the vicinity of intrusive dikes.

A SOLUTION of hyposulphite of soda dissolves lead carbonate, and other oxidized products of lead sulphide, manganese oxide, and copper carbonate, as well as silver chloride. A loose, friable silver ore containing chloride and bromide of silver might be leached satisfactorily by hyposulphite solutions. Tests should be made on fifty-pound lots, the assay before and after leaching showing the result.

THE rock specimens from Oasis, Cal., are: No. 1, quartz, evidently the result of alteration of a granular rock, such as granite or grano-diorite. It may contain gold, though none is visible in the specimen. No. 2 is a dike rock, much decayed, but probably diorite. No. 3 is quartz carrying iron oxide and showing a little malachite (green copper carbonate). This rock may also be gold bearing.

AMMONIUM AMALGAM is formed by treating a solution of ammonium chloride with a compound of mercury and sodium (sodium amalgam). It is a substance difficult to keep because of its unstability. When in the process of making the ammonia amalgam swells up, until it occupies about twenty times the volume of the sodium amalgam. It quickly breaks down at ordinary temperatures into mercury, hydrogen and ammonia.

TWENTY miners' inches of water to develop 20 H. P. would require a head of about 500 feet, though a larger amount—100 inches or more—would develop 1 H. P. per inch, on a somewhat lower head, the difference being due to friction in the pipe line. To secure this efficiency the wheel and nozzle employed should be suited to the existing conditions. A wheel either too large or too small would not produce the full power.

IN the cyanide treatment of ores, as in amalgamation, those at and near the surface are generally found to require a different treatment from those below the water line, and those of the intermediate zone are sometimes the most difficult to successfully treat, owing, usually, to the existence of more or less mineral in the form of sulphate. Often with depth silver appears in an ore which had previously been only gold bearing.

WHERE gold precipitated in the vat of a chlorination plant is of brick red instead of dark brown color, it is probably due to the fact that too little ferrous sulphate has been added. Lead, if present, will also be precipitated, and to avoid mixing with the gold, the lead should first be precipitated as lead sulphate, by addition of sulphuric acid. The clear solution is then decanted to another tank and the gold precipitated with ferrous sulphate.

IN retorting gold or silver amalgam it is not necessary to raise the heat to a point higher than necessary to volatilize the mercury. If the heat be too high the gold or silver are likely to melt and will then adhere to the iron retort and give much trouble in its removal. Mercury volatilizes at about 360° C., and gold melts at 1240° C. and silver at 1000° C., a wide difference between the volatilizing point of mercury and the melting point of gold and silver.

FREQUENTLY large ore bodies occurring within a definite zone are apparently independent of each other, being found in the form of lenses. These may appear as a succession of lens-shaped bodies following each other along a common strike, but more frequently they overlap at the ends, though they may be separated by hard and barren rocks many feet in thickness. The whole zone indicates a common origin, and what is found to be the condition horizontally is often also found to be repeated in depth.

THE Augustin process is a method of extracting silver from matte, and other products of smelting. It is accomplished by roasting the material to be treated with salt, forming the silver present into chloride, which is then leached out by means of hot salt solution, the silver being precipitated on metallic copper. By what is known as the Ziervogel process silver is extracted from roasted silver-bearing copper matte, by washing it out with hot water in the form of silver sulphate. The silver is precipitated on copper in this process also.

GOLD ORES containing considerable graphite do not amalgamate readily. Ores of this character occur in the form of lenses and zones in schists and slates. If ores of this character are crushed and run into a tank before amalgamation, a great deal of the graphite will float away on the surface of the water. The pulp may then be reground and amalgamated. The success of the operation depends to a great extent upon the amount of graphite that is disposed of. In instances where the gold is coarse, concentration without amalgamation may give good results. Gold ores containing molybdenum may be treated in much the same manner.

A LEAK in a water pipe line under pressure may sometimes be stopped by placing a band of iron, several inches in width, and supplied with lugs at the ends to clamp the band about the pipe. This band should not fit too tight, but permit of inserting sheet lead packing between the band and the pipe, which must then be calked carefully. Another method of stopping a leak on a pipe line at a joint is to turn up the edge of the outer pipe, with an old half-inch chisel, sufficiently to insert a piece of baling wire. This should completely encircle the pipe, the ends meeting. When this wire has been driven under the pipe about three-eighths of an inch a string of oakum should be caulked in and a second wire placed against it and carefully caulked. The upturned edge of the pipe may then be hammered down carefully and crimped over the wires; and if the work has been carefully done, the leak will be stopped.

A METHOD of testing zinc in ore volumetrically is to take one gram of pulverized ore, treat with 25 cubic centimeters of aqua regia in a 250 c.c. beaker; cover with a watch glass and heat until the ore is completely decomposed; remove cover and evaporate to near dryness; add 25 c.c. nitric acid containing all the potassium chlorate it will dissolve; heat gently until all of chlorine oxide has passed off and evaporate to dryness, but do not overheat; cool and add 7 grams ammonium chloride, 15 c.c. ammonia and 25 c.c. hot water; cover as before and boil one minute; filter and wash precipitate with hot 1% solution of ammonium chloride, slightly ammoniacal. If precipitate of hydrate of iron and alumina be considerable, it will include some zinc, in which case it should be redissolved in the nitric acid solution of potassium chlorate, evaporated to dryness and the residue treated with ammonium chloride and ammonia and water, as before, and the two filtrates combined. Copper, if present, will be indicated by the blue color of the solution. To remove copper, neutralize the solution with hydrochloric acid and add 10 c.c. strong hydrochloric acid in excess and place in solution a strip of sheet aluminum 2 or 3 inches square; heat solution to 70° C. until all copper is precipitated and solution is colorless; take out aluminum sheet and the solution is ready for titration with standard solution of ferro-cyanide, using the uranium nitrate or acetate solution as an indicator. Its volume should be about 250 c.c. The ferrocyanide solution is made by dissolving 45 grams of potassium ferro-cyanide in one liter of water; 1. c.c. of this solution will be equivalent to about 1 gram of zinc. The metallurgy of zinc is more complicated than that of most of the other common metals, and care in carrying out the operations must be observed throughout.

THE rocks of the earth's crust are grouped under the general terms of sedimentary, metamorphic, intrusive and volcanic. The sedimentary rocks include sandstones, shales, limestones, and certain residuary deposits, like rock salt, gypsum, Colemanite (calcium borate), etc. These rocks, when subjected to heat and pressure, are altered. The constituent minerals become changed and assume a crystalline form, and the rock becomes quartzite, slate, schist, etc. In the quartz sandstones often silica is deposited, each grain of quartz being surrounded by an envelope of silica, which assumes a crystal-like form. This is known as the re-crystallization of sandstone, the result being quartzite. This phenomenon can be studied in thin section under the microscope. All sandstones are not of this class, however, nor is the cementing material in quartzite always silica alone. Lime and iron also often act as a cementing medium. Intrusive rocks are those which are forced up into the outer portions of the earth's crust, but which are generally supposed not to have reached the surface. Among rocks of this description are diorite, quartz-porphyry, granite, etc. These rocks are called intrusive. Volcanic rocks are those which are forced up from below in molten condition, and reaching the surface overflow. These rocks are known as effusive. Types are basalt, rhyolite, trachyte, etc. There are a great many phases of metamorphism due to various causes, and it affects rocks of both sedimentary and igneous origin. Limestone is metamorphosed into marble, and diorite may be changed to amphibolite schist, clay shales may become chiastolite schist, or hard dense slate, etc. Where rocks are changed over wide areas by metamorphic processes it is known as regional metamorphism. Where the change in the original condition of the rock is due to the intrusion of igneous rock, it is known as contact metamorphism. Volcanic rocks may be solid, as in the case of basalt, or may be fragmental, as in tuffs and breccias.

Some Varieties of Wood Battery Guides.

Written for the MINING AND SCIENTIFIC PRESS by W. J. SHARWOOD.

The object of guides iu a stamp mill is to ensure the vertical position of the stems, and diminish as far as possible lateral motion and vibratiou, while reducing to a minimum the frictional resistance, both to vertical travel and to rotation. Those portious of the stems which pass iuto the guides should approximate as closely as possible to true cylinders, and, while considerable deviations are sometimes allowed, the axes of these cylinders should not only be vertical, but should lie in the same vertical plane which passes through the middle liue of the mortar bottom; the guides must be correspondingly placed.

The annexed figures, most of which are sketched without scale, show a number of varieties of wooden guides.

The earlier non-rotating mills had square wooden stems, and two pairs of parallel beams, with short crosspieces between the stems, acted as guides. Two examples of such guides, as used in the sixteeuth ceutury and taken from Agricola's treatise, are shown in Figs. 1 and 2. Almost exactly the same arrangement could be seen in Cornwall a few years ago, and is probably at the present time in use there, except that thin slips of hard wood were fastened either to the stems or guides, so as to be replaceable when worn. In some early California mills the bridge-tree was utilized to form the guide (Fig. 3).

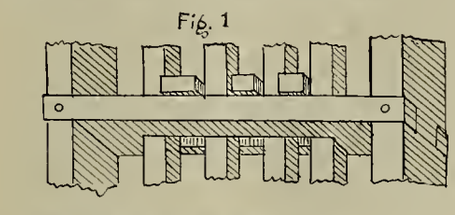
At the present time the guides proper are made detachable from the guide-beams or bridge-trees, aud the upper guide-beam is ofteu placed about 7 feet, or about half the length of the stem, above the lower—measuriug from center to center.

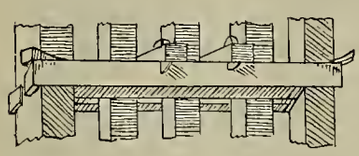
For many years most of the Californian mills were equipped with guides of the style shown in Fig. 6—solid wooden guide-blocks, 3 to 4 inches thick and 12 to 16 inches deep, each with five grooves so formed that, when the guides were placed about ½ iuch apart, the openings corresponded to cylinders of the diameter of the stems. In use they were kept at proper distance by means of keys, and held together and to the beam by collar bolts. The keys were either tapered as showu, or were flat slips of wood, or even pieces of rubber belt; if flat they were kept from slipping out by a projection, or by a nail driven through the upper end. As the guides wore, the space between them was similarly reduced by withdrawing the taper keys slightly, or by thinning the flat keys, and screwing up the nuts. Fiually, when the guides were screwed close, or if worn very irregularly, they had to be removed, faced off, and the grooves ploughed out. When adjusted or trued up it was necessary to "shim up" the back guide, so as to again bring the center liue of the stems to agree with that of the mortar. Fig. 7 gives the usual dimensions of a solid guide and beam for a 12x24-inch battery post.

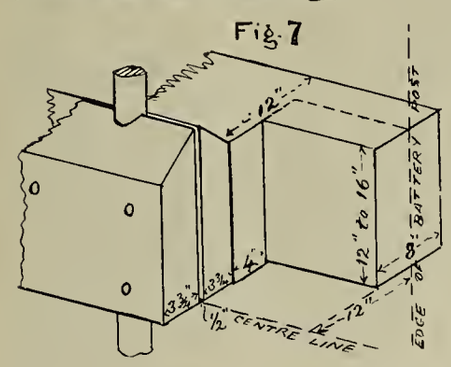
Iu some of the older mills the top and bottom guides faced in opposite directions (Fig. 4); in the newer mills the guides—of whatever make—are so placed that tbe covers are both ou the side farthest from the cam shaft (Fig. 5).

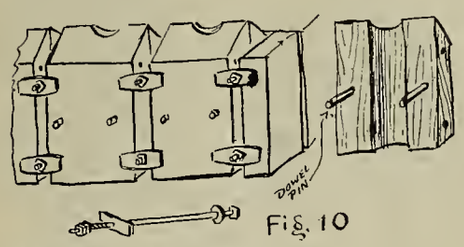
With the solid guides, especially in mills which were not furnished with an overhead "crawl" and chainblock, much time was lost in takiug off guides, as the removal of the solid front guide uecessitated the hanging up of all the stamps in a battery. With the sectional patterns any stamp can be hung up and its guides removed and replaced without interfering with the work of the others, except when the one under repair happeus to be a feed stamp. For this reason sectional guides are very much to be preferred, and a number of different styles have been devised. Some of these are shown in Figs. 8 to 15. In some, as in Figs. 8 and 11, the latter from the Camp Bird, Colo., mill, the back guide is solid, but each stem has a separate front guide or cover, the grain of the wood being horizontal; in others both back and frout are divided, and the grain vertical. Still another plan is to make the division between the two sections of each guide at right augles to the guide beam, as is done in the Acme and Fargo guides (Figs. 14 and 15), giving an end adjustment by means of wedges drawn up by bolts. The same effect is secured by the use of links and set screws in the Broughall guide (see Louis' "Handbook of Gold Milling," page 249) but both this and the Fargo have an undesirable number of parts. Another variety of the Acme, which appears to be a very satisfactory type of guide, is given in Richards' "Ore Dressing." Another class of guide has been evolved from the practice of inserting hardwood bushings into recesses in the solid guides, such as Fig. 3 or 6; an example is showu in Fig. 13, taken from a mill of English design; the Hancock and the Richards, made by the Sandycroft Foundry, are of this type. They seem to be less convenient than the forms in which each stamp has a guide which is entirely removable without in any way disturbing the work of auy others in the battery.

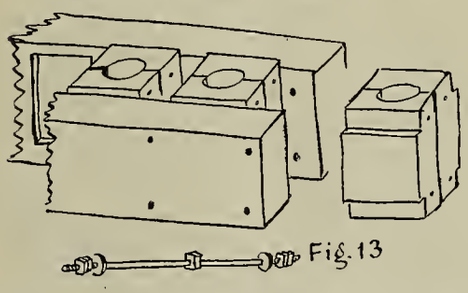
Either of the two distinct principles may be followed iu designing either solid or sectional guides; the two portions may be kept apart by wedges or keys, or the grooves may be true half cylinders, so that the two sectious must be brought close together. The latter is the preferable plan, aud is generally adopted with sectioual patterns, but in either case the covers should be tightly screwed up, so as to prevent any motion of the cover, which tends to increase the wear. If any grit is allowed to enter from above, or to splash up iuto the lower guide owing to imperfect covering of the mortar, the wear may be excessive. When once started, wear goes on with increasing rapidity, so that it is desirable to keep guides set up as closely as possible and adjust them as soon as auy play begins to show itself. The device shown in Figs. 7 and 10, taken from the Soulsby mill, of mitering the tops of the guides or guide blocks, is a very useful one, and costs practically nothing; it effectually prevents dust which may lodge on a guide from getting into the working parts. It is important to secure the guide-blocks against vertical motiou. This may be done by dowels, as in Fig. 10, if the main bolts do not pass through them. Owing to its usually wearing

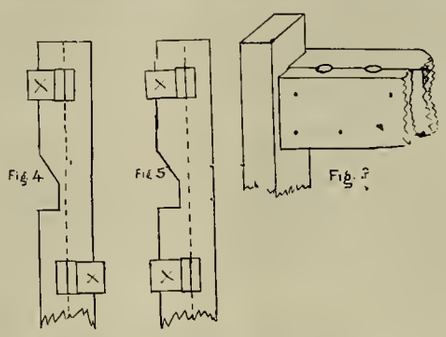


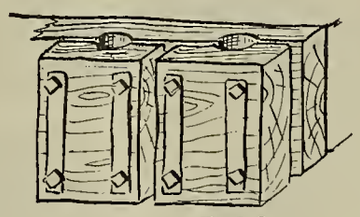


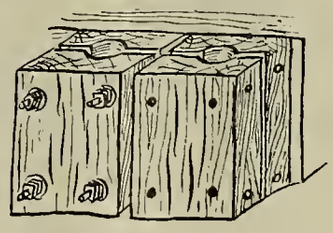


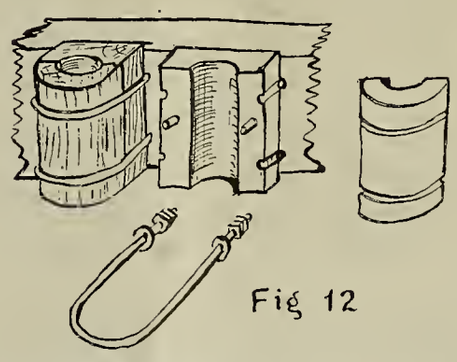


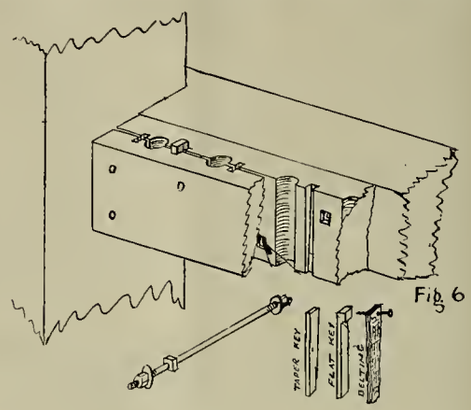


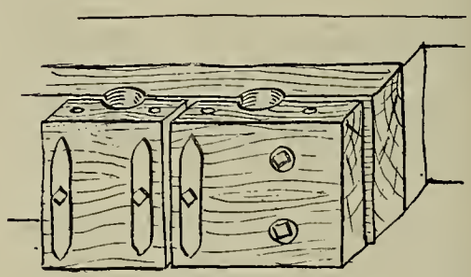


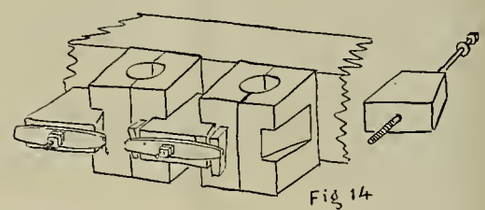


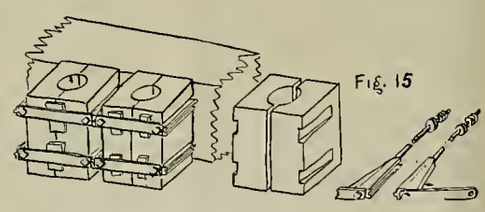












somewhat faster, it is quite a common practice to make the lower guide beam and blocks 2 inches deeper than the upper, but with sectional guides it is desirable to have as few patterns as possible, and therefore some prefer to make all of the same depth. For the same reason there are advantages in adopting some such style as Figs. 10 or 14, in which only one pattern of block is used for front and back, and for top and bottom, if these are both of the same depth.

General experience shows that the wear is less in amount and more uniform, both on stems and blocks, when the latter are made of moderately hard wood, with the grain vertical. Various woods have been used, oak, beech, pine, occasionally nut pine in California, certain varieties of eucalyptus in Australia, and maple; the latter seems to be generally preferred. Splitting is guarded against by running a ⅝ bolt, countersunk, across the grain at each end of the blocks (Figs. 9, 10, 11).

Following is a description of the several figures referred to in the text:

Figs. 1 and 2. German guides of sixteenth century for square stems, from Agricola.

Fig. 3. Guide for round stem, groove cut in main beam.

Fig. 4. Old method and Fig. 5 usual method of placing guide beams.

Fig. 6. Common solid guides, fitted with taper keys.

Fig. 7. Solid guide with bevelled top.

Figs. 8 to 12. Various types of sectionall all-wood guides.

Fig. 13. Recessed wood-frame; Sandycroft type.

Fig. 14. End-adjusting guide with wood wedges; Acme type.

Fig. 15. Fargo guide, end-adjusting, with tongued and grooved iron wedges.

The Crown King Mill, Yavapai Co., Ariz.

The Crown King mill, illustrated herewith, lately taken over by an Eastern company, with G. F. Shurtleff, manager, is at Crown King, in a section of the Bradshaw mountains, southeast of Prescott, being opened up by the Bradshaw Mountain Railroad. The rails will soon be laid to this point and development of the district will again be under way. The

The Crown King Mill, Yavapai County, Arizona.

mill has been entirely remodeled and the first work will be treatment of the old tailings dump of the Crown King mine, estimated at about 40,000 tons. The tailings dump has been tunneled and a belt elevator installed so as to handle them with economy. The tailings will be passed through a Jeffrey drier to a storage bin, and from this by plunger feeder to Dimmick classifiers and then onto Wilfley tables and Frue vanners. The concentrates will again go to a drier, then to storage bin and roaster. They then pass to magnetic separators and the zinc product is handled separately from the iron. The process has been specially adapted to the conditions there. It is expected that treatment will be commenced by July 1. The company is said to have under consideration the taking over of the Crown King mine also, and in addition has an option on the Tiger group, consisting of seven and a half claims and mill of the Tiger Gold Co. in the same vicinity.

THE next meeting of the Idaho State Mining Association will be held at Boise, Idaho, on the 19th and 20th inst.

Radium Ores in Utah.

Written for the MINING AND SCIENTIFIC PRESS by DON MAGUIRE.

Since the discovery of radium in uranium ores by the Curies of Paris, much interest has attached to uranium deposits everywhere. Some weeks ago, accompanied by an assistant, I visited the carnotite deposits near Richardson, a small hamlet in Grand county, Utah, and made an inspection of the interesting deposits which have been opened there.

Richardson is reached by wagon from Cisco, a station on the Rio Grande-Western Railroad, about 250 miles southeast of Ogden, in a region of red sandstones. Richardson is 30 miles distant from Cisco, in a direction a little west of south, and near the Grand river. Large tracts of land in the country between Cisco and Richardson have been located for oil, but without profitable result as yet.

At Richardson we found J. H. Loftus of the Welch-Loftus Rare Metals Company, who accompanied us and afforded us every opportunity to inspect the properties of the company, situated amid low hills about 3 miles to the southeast. The formation is sandstone, mostly red; but the mines occur along the crest of an anticline, which has been eroded somewhat, exposing lower strata of whitish-gray sandstone. The axis of the uplift is about east-west.

In the gray sandstone are numerous fissures, due to the flexing of the rocks along the anticline, some wide and some narrow, exposing a rich yellow mineralization. These upon being opened by mine workings are found to widen with depth, and the mineral thus exposed is carnotite (uranium oxide), the mineral from which radium is produced.

Radium once seen is never forgotten. There is no other mineral or ore just like it. There is a saying among placer miners that many things resemble gold, but that gold resembles nothing else. This is true of uranium oxide, or radium-bearing carnotite. There are many minerals bearing some resemblance to carnotite, but carnotite resembles nothing else. In color it is a bright, beautiful canary yellow, once seen never to be forgotten. Seen massive or in its frequently scaly state, the smallest fragment attracts the eye and can not be mistaken for anything else. At times its rich yellow or orange changes into a yellowish green, and this has the same appearance peculiar to itself.

At the mine known as the Rare Metals Group we found much work done, chiefly prospect holes along a distance of half a mile in length and less than 100 feet in width; but in each of these uranium oxide is present. The main shaft is about 100 feet in depth. The mineral shows the full width of the shaft to the bottom. A drift is driven to the east 50 feet in the ore. Near the mouth of this shaft there is a dump rich in coloring, and at the time of our visit about 200 sacks were piled ready for shipment. There are one or two more workings east of the main shaft in which ore shoots are prominent, and in the prospect holes to the east and west we found ore abundant where any work had been done.

A close examination of the ore piles disclosed the fact that both silver and copper are associated in this ore. Copper occurs native and as chalcocite and malachite, and, with it, silver, as black sulphurets.

Investigation over the region proved that a mineral zone extends a distance of 140 miles in length and 50 miles in width. It extends eastwardly into Montrose county, Colo., where at the silver-copper-bearing mines of Paradox valley silver-copper ores of richness are now being worked by an Eastern company, and adjacent to these mines at Paradox the ores of carnotite also occur.

At Paradox valley, in Colorado, uranium sulphide, carnotite and pitchblende, from which radium is obtained, exist in amorphous masses.

In these white sandstone reefs small pipes leading from other lenses are evidence of currents having been present in every case, and these lenses are in thickness varying from ¼ inch to 3 inches and in extent from 1 foot to 10 feet. I have been informed that some lenses have been discovered in which the yellow caruotite exists in masses 1 foot in thickness; but we did not see any such examples. In the mines opened up at Richardson very little amorphous carnotite occurs. It is wholly in a crystallized form, occurring as scale-like crystals along the minute fissures in the mineralized sandstone.

This Montrose county, Colo., and Grand county, Utah, region is the most extensive area of our country where these radium-producing ores are known.

At Richardson, Utah, the lode in which we find these ores strikes across the country slightly south of east and north of west. We followed its course to the north side of the Grand river, where in the high cliffs the mineral is exposed, and we found small inclusions of covellite, bornite and malachite associated with the orange-colored carnotite, and invariably these copper ores run high in silver. To the east and southeast similar ores occur along the strike of this lode into Castle valley and continue down into Paradox to the southeastward, where, as stated, the radium-bearing ore appears in more massive state.

There are other localities in Utah where caruotite is found, namely, near Vernal, on Ashley's Fork, Uintah county; also in the country lying east and north of the Henry mountains, in Garfield county; also at the old mines of Silver Reef and near the town of Washington, in Washington county. In every case where it is found it occurs in white or gray sandstone and usually associated with silver and copper ores. With it are found traces of organic matter showing the imprints of ferns, palm leaves, cones and of other organic remains. The carbon in such cases, it is thought, acted as a precipitant for the silver and copper.

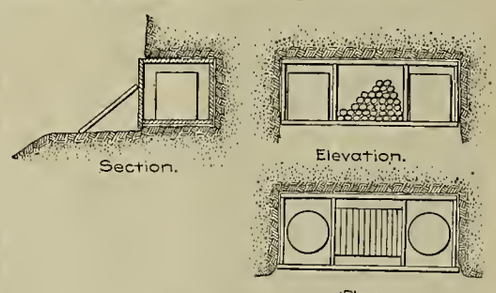
The area favorable for the production of carnotite in Utah, Colorado and Arizona is about 35,000 square miles, much of which has never been explored, as it is cut by tremendous canyons and favored with neither wood, grass nor water.

The region described is that in which the cliff dweller made his home, and he who passes through this desolate but most interesting country sees on every high plateau, in every canyon and along the narrow strips of arable land skirting the canyons the cliff dwellings of a people long since gone.

Thawing Dynamite.

The danger attending the thawing of nitro powder is becoming better understood each year and fewer accidents due to this cause are chronicled now than formerly. Still, new men are constantly coming into the mining business and a word of caution and advice on the subject is always appropriate, though the "old hands" are more prone to carelessness than the new ones. The following, written by J. H. Harper, in Engineering News is of interest:

Some four or five explosions of from one-half to two boxes of giant powder have occurred upon work under my supervision within a period of about five



Device for Thawing Powder.

years, all, very fortunately, without fatal results, though in at least two instances a very slight change in time or circumstances might have resulted in a very distressing accident.

During the past winter I noticed that J. McCrimmon, while working upon a cut a short distance east of the Mullan tunnel, on the main line of the Northern Pacific Railroad, in Montana, was using an arrangement for thawing dynamite that apparently gave entire satisfaction, and I enclose herewith sketches thereof.

Mr. McCrimmon found a pit in the ground which he utilized for the purpose, but I show it as cut into a bank, although the box might be used on level ground and covered with earth to a depth that will secure an even temperature. The box is constructed of such materials as are generally available. The cans

used were discarded powder cans, but coal oil caus answer quite as well, and almost any discarded vessel will answer.

Twice a day, or oftener, if necessary, the water is turned out and the cans are filled with boiling water. The powder is piled between the cans, as shown, or the chamber may be made large enough to receive one or more unbroken boxes of powder. Where the ground will stand, the exterior box shown is not required unless it be to assist in making the door with which the front is closed—air tight. An old blanket or tarpaulin will often serve this purpose well.

The idea is not altogether new, perhaps, as I have seen many arrangements very similar to this, but none, I think, which is more easily made, of material usually available and which is, so far as I can discover, without an element of danger that is not inherent within the powder.

A small air tight pit of this construction will, with little attention, keep a constant supply of powder in perfect condition through as severe weather as men are likely to wish to work. The Hendrie & Bolthoff Mfg. & Supply Co., Denver, Colo., furnish a powder thawer that is safe and effective.

Cyaniding Gold-Bearing Sulphurets.*

NUMBER II.

Written by S. B. Christy.

Any one may extract with a large magnet the magnetic particles of metallic iron in the center of the rusty aggregates found in vanner concentrates. An electrolytic action seems to be set up by the presence of the metallic iron in the damp ore, favoring the formation of ferrous salts.

I took a powerful magnet and ran it through the concentrates as they came off from the vanner at the Melones. I took about 5 grams of this magnetic product, mostly iron, with some sulphurets sticking to it, put it into a beaker with about a tumbler full of cyanide solution, which on the 19th of July, 1899, assayed 0.55% cyanide at 2:30 P. M.; at 4:45, a little over two hours later, it had dropped to 0.45%; at 6 o'clock it had dropped to 0.35%; and the next day, twenty-four hours later, it had dropped to .005%. That very clearly shows the destroying effect of this agent.

I took some concentrates of this same ore which had been allowed to accumulate. This was sent down to me at the University of California, and I ran them through a small magnetic separator. I got out a large amount of magnetic material, most of which was metallic iron, iron rust, etc., and I had one of my students treat that in a leaching tube for a week. No cyanide came through until after a week had passed. That is, the cyanide solution was destroyed during its continuous passage through these iron filings for over a week, and the extraction of gold was nil. That showed how important is the removal of the metallic iron from the sulphurets. Not only does the iron in a fine state of subdivision destroy the cyanide, but it absorbs oxygen from the air, which is necessary for the solution of the gold. So, it acts badly in two different ways. Before I understood that I had some very contradictory results. I ground the concentrates in an ordinary amalgamating pan, as one would do with silver ore, and on getting it fine enough, if I used cyanide enough, I got a good extraction of gold, but the destruction of cyanide was so high that, until I made the discovery of the cause of it, I did not see any way of making the extraction practicable. But I think that it can be very readily solved.

There are two principal ways by which we can crush the concentrates as finely as we wish without using any iron in contact with the ore we wish to crush. One is by using the arrastra and the other by using the flint mill, or the revolving tube mill, by which the ore is crushed by boulders of quartz or flint without coming in contact with any metallic iron. While these two methods are mechanically very primitive, they do the work satisfactorily, and I think could be improved mechanically by a little ingenuity. The arrastra I have used is not the ordinary rough arrastra, such as is built out of rough stones by the Mexicans, but one built in an iron frame by lining it with a layer of 6 inches of concrete. I crushed up some granite and made a strong concrete about 6 inches thick and lined the whole arrastra with that. Then as mullers I use blocks of basalt, or blocks of artificial stone made out of concrete, and these are dragged over the surface, and the ore is crushed to an impalpable powder. I have ground the ore for various periods of time, sometimes eight hours, some times twelve, sometimes twenty-four, and in this way I have been able to produce a product which is fiuer than you could ordinarily get a sieve fine enough to sift it through. It is much finer than 200. One hundred is not fine enough—the finer it is ground the better. It does not need to be sieved. When I wish to size it I do so by an uprising stream of water. This washes out all the slimes, and the coarse particles are reground, if necessary.

I have always found after cyaniding that the coarse sulphurets carried the value, and that the values in the fine were extracted very readily.

The arrastra is a very efficient grinding machine, although very primitive. It will do good work, particularly on sulphurets which are not hard to grind. The arrastra can be built very cheaply, made of quartz battery sand on the spot, aud if it wears out can easily be replaced by putting in a little more concrete in the worn places, so the cost need not be excessive for the grinding machinery. The cost for power is also very light, if you have water power available.

The other method of grinding is one used by paint and drug manufacturers. That is the ordinary flint mill. Constructed for these purposes it is very expensive. It is a revolving cylinder lined with porcelain liners, in which there are round pebbles of hard flint, but as constructed for our purpose, it could be easily improvised from a revolving cylinder made of iron, lined on the inside with concrete with loose quartz boulders inside, such as we get in our gravel mines, instead of the flint pebbles. In this case the discharge can be regulated by the amount of inflowing water through hollow trunnions; the right amount of water can be allowed to flow through the machine and wash out only the finer slimes. Which of the two will prove the most satisfactory depends on local conditions.

The fourth idea, then, is that iron must not be used in grinding. We must grind in some machine which will not produce iron filings.

Fifth, the solution of the gold.—This part of the operation, if properly done, is not very difficult. The gold cannot be extracted by downward filtration, for the reason that the ore is so fine it practically resists filtration. I have had a layer of slimes not more than ¾ inch thick, through which I was able with a pressure of 300 pounds to the square inch, to force through a filter about 6 inches square more than one or two drops of solution per minute. So you can readily see that it is not filterable. Some variety of agitation is necessary. You are familiar with the traditional agitator, which is a set of revolving arms contained in a cylinder, such as was formerly used to separate amalgam from the pulp from amalgamating pans. This is used in many cyaniding plants successfully, but it is troublesome, because if the machine is allowed to stop, the pulp all settles to the bottom and packs like hard cement, and is extremely difficult to get in agitation agaiu.

Another method would be a revolving barrel, the barrel containing the ore and water in suspeusion. On rotating that, it is kept in agitation very readily, and if it settles it cau be easily stirred up by rotating it. That is a practicable method, but only practicable with small quautities of ore.

The method I have used and found most satisfactory is to use a cylindrical vessel with a conical bottom—that is, a cone making an angle of about 130°, with the cylindrical sides above. Into this cone-bottomed cylinder the ore is dumped with the cyanide solution, and is stirred by mcans of compressed air. A pipe reaches to the bottom, and in this way the air is forced down to the point of the cone and rises up through the mass and produces a circulation of the whole contents. The largest sized vessel I have used is a tank 18 inches in diameter. If it is made larger than that I apprehend several air jets would be required, but with one of that size I was enabled to get good circulation with one jet. The pressure of the air is very slight. It is only cqual to the column of water that is to be lifted, only a few pounds, and where one has a water pressure it is very easy to make an air compressor out of the jet pump. You don't need to buy an expensive air compressor for the purpose. One would think that the passage of the air through the cyanide solution would cause a great loss of cyanide. And so it would if the cyanide solution were strong, but with the weak solutions I have used I have found the loss is only nominal, and if the air which is used can be caught and used over again, practically no loss of cyanide would ensue, even with strong solutions.

The use of the air as a stirring means is also advantageous, because it produces the necessary oxygeu for the solution of the gold. Under favorable circumstances, with ores which were amenable to treatment, I have extracted 99.9% of all the gold present in the sulphurets, sulphurets showing $40 or $50 in half an hour, and even in less time than that. I have taken the volume of the gold solution there and the assay value of the solution in it, and accounted for all the gold up to .1%. As a matter of fact, I find it usually necessary to allow about three hours for treatment—that is, the circulation of the pulp by means of compressed air usually lasts about three hours, and in all except the very difficult ores that suffices, and we get the gold dissolved in this way very readily. I have not found it necessary to resort to any oxidizing agents (although I have used them of all sorts, including bromo-cyanide, peroxides of sodium, of maugauese, of barium, and other chemicals), but I have found the air the most efficient and cheapest of the oxidizing agents, and I have not found anything else give much better results. I have usually used diluted cyanide solution, and I have extracted most ores with solutions that did not go higher than .1% cyanide. Once in awhile I have had to use .2%, but usually only .1%, which is much lower than was formerly supposed to be practicable with such rich ores.

The solution of the gold after you once get the sulphides in a fine state of subdivision is comparatively easy. It is the easiest thing connected with the whole process, but the next step is not so easy—and that is: The removal of the cyanide solution from the ore. That is a part of the operation which has given me the most trouble, aud will surely do so in any case. As I have stated, the fine state of subdivision of the ore is so great that filtration downwards in the ordinary way is impossible. The use of the filter press is possible in some cases, but I consider it from my experiments rathcr impracticable. If the ore is coarse enough to use the filter press, it is usually not fine enough to get the gold out. You are familiar with the filter press. It is a machine in which the ore is pumped into filter chambers, which are not more than, say, 1 inch or 2 inches wide and from 1 to 4 feet square. There are filter cloths on each side of the chamber, backed up against a grooved plate, and the solution passes through the cloth and leaves the ore behind. The solution is pumped in under pressure. Although it has been successfully used on many ores, and if we were to mix the slimes with quartz sands we might be able to use a filter press, I think on the whole it is not the best mode of treatment.

The simplest method we can possibly use is decantation. That is, instead of trying to let the material filter, we let it settle, and as the sulphurets are very heavy and the quicklime used to neutralize the acid helps to settle the stuff, it settles perfectly clear. The clear solution can be drawn off and sent to the precipitation tanks, but the ore is so fine that, let it settle as long as you please, it always holds a large amount of solution in its pores. The amount of solution left in these fine slimes varies from one-half ton of solution to a whole ton per ton dry pulp. If the ore is extremely fine, unless much time is given for settling, it will hold nearly a ton of solution. This solutiou contains gold and contains cyanide which must be removed. The most convenient method I have found to operate is to use the solution cylinder with cone bottom for the decantation processes—that is, I decant in the same vessel in which I dissolve the gold. I have this cylinder coming dowu to a conical point at the bottom. In this I have a stand-pipe reaching up above the top of the solution, and at the bottom this is ordinarily closed. On top of the stand-pipe, and outside of it, I put another piece of pipe a little larger than it for blowing air in. Ordinarily I had the stand-pipe filled with water and stopped at the bottom, so when I blow air in the air goes down on the outside of the stand-pipe and emerges at the bottom, bubbling up through the ore, circulating the pulp and dissolving the gold. When I wish to decant the solutiou, I let it settle for three or four hours, or possibly in some cases over night, and the mud all settles at the bottom. At first it lies perfectly flat at the bottom, but as the deeper part contains more precipitate, it finally settles in the form of a flat coue, flatter thau the big cone. On disconnccting my air pipe from the air compressor and producing a vacuum by air pump, I produce a siphou out of the outer and inner pipe. That is, the solution is sucked up the outer pipe and goes down the inner pipe and the solution, clear and freed from mud, flows out through the stand-pipe and runs away to the precipitating tank. I lower the air pipe gradually down, following the water as it goes down very carefully, and in this way, using a tank with a conical bottom, I can run it down to the very bottom of that mud cone and take off all the clear solution. In that way I have been able to decant off much closer thau you could possibly do in a flat-bottomed tank. Practically all the solution runs out of the cone, and I don't lose possibly more than a teaspoonful of the clear solution. It is very important to make that decantation as complete as possible. I then fill the tank up with fresh water and stir again with compressed air, lowering the pipe down gradually to get it all in suspension, and let it settle again, and repeat the process of decantation as many times as may be neccssary to draw off the cyanide solution.

Now, there is an important principle regarding this decantation which is worthy of careful study, and I shall try to explain it.

That is, the rapidity with which gold-bearing solution is extracted depends upon the proportion existing between the volume of solution drawn off each time to that left in the pulp. Suppose I have one ton of ore and ten tons of solution in the tank. That is more than necessary, but to illustrate what I mean I will suppose that. I can now draw off nine tons of water, leaving one ton of solution behind. I will call that a decantation co-efficient of one-tenth. That is, there is one-tenth of the gold-bearing solution left in the pulp, and I draw off nine tons. I decant once, and I have left in the solution one-tenth of all the gold-bearing solution there was originally. I decant again, and I have one-tenth of that, or one-tenth of one-tenth, or one one-hundredth. That is, there is one oue-hundredth of the gold solution left in the ore. A third time would give me one-thousandth. A fourth time one-ten-thousandth. And a fifth time one one-hundredth-thousandth. Now, let me call your attention to the large amount of solution that would be necessary for this ratio. The first time I would have run off nine tons, the second eighteen, the next time it would amount to twenty-seven, then thirty-six, and finally forty-five. That is, to handle one ton of ore in that way I would have to handle forty-five tons of the solution. The bulk of the solu-

*Abstract Trans. Cal. Min. Ass'n.

tion is something enormous, and the time of the decantation very great. To diminish this, suppose I go to the extreme limit and have only two tons of solution to one ton of ore. If I let that settle I draw off one ton. I have one-half left. The second time I have one-half of the half, or a quarter. The third time one eighth, the fourth time one-sixteenth, and the fifth time one-thirty-second. That is, there would be 3% of the original solution left in the ore in five decantations in this case. But here I would use the first time one, the second two, the third three, and the fifth time I would have five tons of the solution which I would have to precipitate. So you can see if I make my decantation co-efficient small, that is one-tenth, I get quick removal of the solution, but I have a large quantity of the solution to handle, and to precipitate. I have generally found that a decantation co-efficient of about one fourth is practicable. That is, I would have four tons of solution to one ton of ore. I decant off three tons each time, and that way I would bring it down to about 1½% in three decantations, and would have only nine tons of solution to precipitate per ton of ore.

(TO BE CONTINUED.)

Wet Methods of Extracting Copper at Rio Tinto, Spain.*

NUMBER II.—CONCLUDED.

Written by C. H. JONES.

Each series consists of three tanks in parallel arranged so that the liquor can be divided up and passed along as many tanks as necessary, depending on the quantity of liquor that is being run through and on the varying temperature of the liquor with different seasons, the hotter the solution, which in summer reaches 100° F., the faster the rate of precipitation. Each tank is about 320 feet long, 5.5 feet wide by 2.25 feet deep, and has a slope varying from 2 per 1000 in the first series to 11 per 1000 in the last, the reason for the increase in slope being, that as the liquor becomes impoverished in copper, the free acid present is more active in wastefully dissolving the pig iron—an action which is considerably diminished by increasing the velocity of the liquor by means of the increased slope of the tanks. The tanks themselves are made of 9x3-inch boards attached to wooden frames set in cement, the space between parallel tanks being filled in with stone and cement, constituting a wall supporting the sides of the tanks.

The Method of Removing the Cement-Copper from the Precipitating Tanks.

The accompanying engraving shows the method of removing the cement copper.

No metal is used in the construction, hard wooden pegs being employed to attach the boards to the frames. The spaces between the boards are carefully calked with oakum and pitch in order to render the tank water tight. At each end of the tank is an arrangement by which a door can be dropped in and luted so as to cut out that particular tank, and there are also wooden plugs that can be removed so that the liquor from that tank can be run off, thus allowing for the removal of the precipitated copper. A few old boards are placed on the bottom of the tanks for their protection and on these are piled up the pigs of iron which are laid across the tank at the bottom, the next layer being at right angles to the first, and so on until the tank is filled; each foot-length of the tank contains about one ton of iron. The liquor is allowed to run through the system of tanks and needs no attention except to remove the precipitated copper and to add fresh iron. The "salida" liquor containing from 15 to 20 grams of copper per cubic meter is allowed to run to waste, for the reason that about this copper content the amount of iron required to precipitate the copper equals the value of the copper recovered. Daily some of the tanks are cleaned out by being closed as described above, the liquor meanwhile passing down the other tanks of the series; the liquor is run off into settling tanks, any copper in suspension being there recovered; all of the iron is removed from the tank and piled on to the dividing wall, at the same time the copper adhering to the iron is knocked off and thrown back into the tank. The dirty looking precipitate is then transferred to the cleaning and concentrating plant, the iron is replaced in the tank and the liquor again allowed to run through it. This crude precipitate, containing about 70% copper, is thrown, a little at a time, on to a perforated copper plate placed at the head of a long launder or tank and is washed through the plate by a strong stream of water from a small nozzle. The material that does not pass through the screen consists of leaf-copper and small pieces of iron; this material is thrown into a heap and afterwards sorted over by girls who remove the pieces of iron. The precipitate that passes into the launder is repeatedly turned over against the stream of water and by this simple means a concentration is effected.

The first few yards of the launder contain a red precipitate known as "No. 1 precipitate," containing 94% copper and less than 0.3% arsenic; following this is "No. 2 precipitate," containing 92% copper and between 0.3% and 0.75% arsenic, while below is the "No. 3 precipitate;" this is in a state of very fine division and contains on an average 50% copper and 5% arsenic. This last named portion, which carries all the graphite from the pig, contains the bulk of the antimony and bismuth that is also precipitated from the liquors. Classes Nos. 1 and 2 are removed to the drying sheds and are bagged for shipment to the refinery; the No. 3 precipitate is removed, moistened with acid liquors, made into balls by hand and dried in the sun. These balls become cemented hard and can be readily transferred to the smelter, where they form part of the charge for the blast furnaces and are run down to matte to be subsequently bessemerized, thus effectively removing the arsenic, antimony and bismuth that they contain.

The reactions that take place in the cementation tanks are given in equations 5, 6 and 7.

The first reaction that occurs in the liquor running over metallic iron is the reduction of the ferric sulphate to ferrous sulphate, the final result being in accordance with the equation:

$$(5)\quad Fe_2(SO_4)_3 + Fe = 3FeSO_4.$$

This action causes the consumption of the pig iron without any corresponding yield in copper, and consequently should be avoided as far as possible by having all the iron in the ferrous state.

The second reaction is the precipitation of the metallic copper, brought about by galvanic action. The iron becomes coated with copper, and thus the iron and copper in the acid liquor constitute a galvanic couple with a considerable difference of potential. It is due to the electrolytic action that the copper and all other metals present that are electro-negative to iron will be precipitated. The ultimate action of the precipitation may be chemically expressed by the following equation:

$$(6)\quad Fe + CuSO_4 = FeSO_4 + Cu.$$

Besides the reactions above mentioned there is one which causes the liberation of hydrogen, as evidenced by the bubbles of gas that may be observed to arise in the tank liquor. This action, which causes a wasteful consumption of the iron, may be expressed as a final result by the following equation:

$$(7)\quad Fe + H_2SO_4 = FeSO_4 + H_2.$$

These three equations constitute the main reactions that take place in the precipitating tanks.

While the liquor is fairly strong in copper, the copper is mostly precipitated in a coherent form, but in the later stages as the liquor becomes impoverished it is precipitated in a powdery state—a condition which is more effective in its galvanic action with the iron, and thus unfortunately causes a larger precipitation of arsenic and other impurities than in the earlier stages. In the later stages also the "solution reaction" of iron in sulphuric acid as given in reaction No. 7 goes on to a proportionately greater extent than does the precipitation of copper, and consequently the cost of pig iron in precipitating the copper varies inversely as the quantity of copper in the liquor.

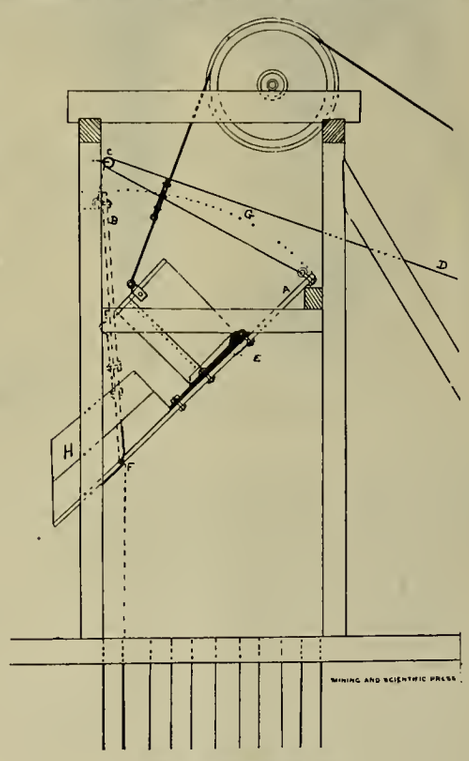
By keeping careful watch on the reduction as far as possible of the ferric iron before the liquor enters the tanks, and by giving it sufficient velocity through the tanks, a strongly acid liquor such as given above during a year's working will not consume more than 1.4 units of pig iron (containing 92% iron) to 1 unit of copper precipitated. A valuable check on the iron being consumed can easily be kept by the laboratory, by analyzing the liquors before entering and after leaving the tanks, and from these analyses the quantity of iron that is being consumed can be calculated.

This description of the methods of leaching and precipitation that are now used at Rio Tinto is offered in the hope that it will prove of interest and value, especially so in view of the fact that most of the information heretofore published pertaining to these methods has become obsolete.

*Abstract Trans. Am. Inst. Min. Engs.

An Automatic Bucket Dumping Device.

About many small mines the problems of economy are closely studied, and the inventive faculty of the superintendent is taxed to find ways and means of doing things economically. At a mine where shaft sinking only is in progress, or a small number of men



Bucket Dumping Device.

are employed underground, there are sometimes several hours when the hoisting engineer is idle, but he cannot leave his post, for at any minute the signal may come from below to "hoist," "send down tools," "send down timbers," or some other requirement, and he must be at or near his post. He has abundant time to keep the engine clean and to prepare during the day for his partner of the night shift. In such a situation it is obviously extravagant to have an additional man on top who one-half of the time will be unemployed, or if he hustle in wood from the outside pile, clean the lamps for night, level off the dump, help in the blacksmith shop, or do other odds and ends about the place, it only affords additional leisure to the engineer. There are mines, however, where one man on top attends to the entire work to be done. He is hoisting engineer, carpenter, timber-framer, blacksmith, carman, fireman and general roustabout, and sometimes adds to these duties the responsibility of superintendent. To accomplish this is only possible by the employment of mechanical devices to take the place of men. The accompanying sketch shows an arrangement whereby a man at the hoist may raise the bucket filled with rock, dump it, and send the bucket back into the mine without leaving his post at the throttle. After the bucket has gone below he goes out and trams the car to the

waste dump or ore pile, dumps it and trams it back to the shaft ready for the next load.

The sketch shows the operation of a simple contrivance for accomplishing this. A door, or apron, is made of strong planks, and fixed on a hinge, F, flush with the line of the inside of the shaft. This apron, when not covering the shaft, inclines backward, and the upper end rests against a cross piece in the head frame near B. When a bucket is hoisted it is raised to clear the dotted line, G (though in the drawing there is not sufficient room allowed by the draughtsman for this purpose). This is an important part of the arrangement, and the head frame should be sufficiently high to permit this, and at the same time permit the rock to pass from the chute into a car standing on the track. A rope, D, passes from the eyebolt at A, over the pulley, C, and to within reach of the engineer in the hoist building. At the further end, in the hoist, it passes over a second pulley and has a counter weight attached to aid in handling the door. It will be observed that the door is not absolutely vertical, but near it when in the position at B. When the bucket clears the line of passage of the top of the door, indicated by the dotted line, G, a smart jerk on the line, D, causes the door to spring outward, and passing its center of gravity it continues toward A until it rests on the cross piece at A. On the upper side of the apron a heavy piece of strap iron is secured by three stout bolts, E (shown in black). This is bent upward at the upper end, forming an obstruction on the otherwise comparatively smooth surface of the apron. The bucket is one of the straight sided kind, having a strengthening band top and bottom, with chimes 1½ inch deep on the under side. The bucket is lowered by the engineer. When it strikes the apron it slips downward a short distance, and the upper edge of the chime of the bucket engages the buckeled strap of iron, and unable to slip downward further as the cable is slacked by the engineer the bucket overturns and dumps its contents into the chute, H, whence it passes to a car which should be placed to receive the rock. The bucket is hoisted above the apron, the engineer again gives the string a vigorous pull and the door assumes its former position at B, and the bucket is again sent below.

IT seems strange that laws should be required to make the equipment of mine shafts with safety devices compulsory; but such is the case. And, worse still, in many cases the law is neglected and has become a dead letter. It is the part of wisdom for every mining company to avoid accident, not only to insure the safety of employes, but it is economy and good business to avoid the expense incident to a breaking cable, a wrecked shaft or a ruined skip or cage, which inevitably always follows a case of overwinding where no safety appliances are provided, or which fail to operate if they have been put in.

The Lone Mountain District, Near Tonopah, Nev.

Written for the MINING AND SCIENTIFIC PRESS by A. LAKES.

The region at the eastern base of the Sierras from the line of the Central Pacific Railroad at Reno, for 300 or 400 miles south, to Tonopah and Goldfield, is one that bears every evidence of great mineralization. It is essentially a volcanic region, all the rocks, with exception here and there of some outcrops of Cambrian and Silurian limestones, are volcanic. The eruptions are mostly of Tertiary age, consisting of andesite, dacite, rhyolite and diorite, with some later overflows of basalt. Volcanity seems, in Nevada, to increase as we approach the base of the Sierras, and may be connected with that great uplift. The evidences of mineralization show it to be both recent and ancient.

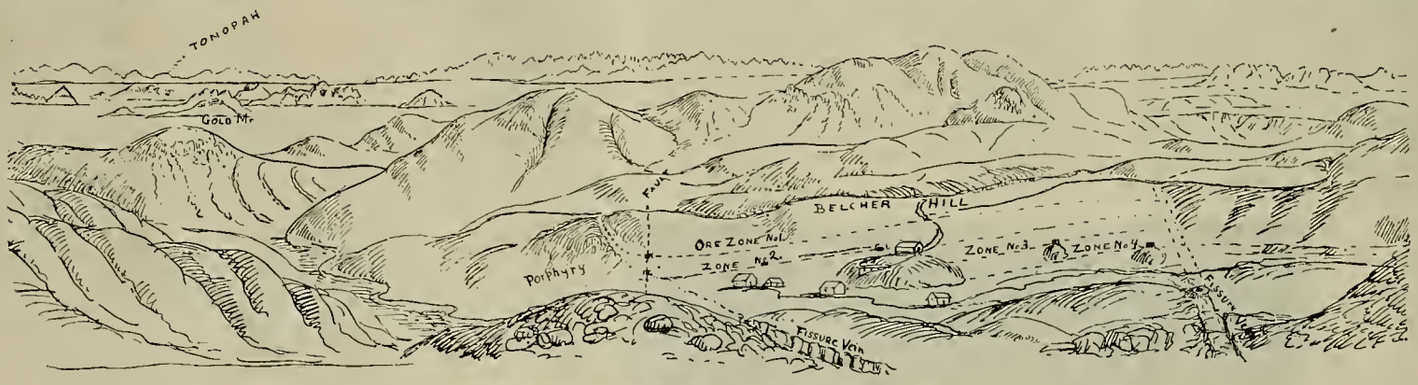
A few miles below Reno we have the Steamboat Springs issuing in puffs of steam and hot water from a series of long parallel fissures near a hill of basalt. Some of these fissures have already been filled with quartz and vein stuff, forming true veins; others are in process of filling with gelatinous silica. Here we have modern fissure veins in process of formation. A few miles further southeast we have the great Comstock fissure, filled and ore bearing, which, as the hot deeper workings show, is following down a retreating hot spring that filled the fissure with gold and silver ore in the same way as at Steamboat Springs.

South again we come to the mining district of Candelaria, where there are fissures in volcanic rocks, and still further south to Tonopah and Goldfield, with their mineralized, fissured zones in andesitic rocks. About 20 miles southwest of Tonopah, at Silver Peak, is a well-defined crater and modern lava flow, while Tonopah itself, like Cripple Creek, Colo., is located on the site of numerous volcanic vents. Tonopah has been described by J. E. Spurr and other writers, so we will not dilate on it here, but pass to one of the districts not far from it which has hitherto had less notice.

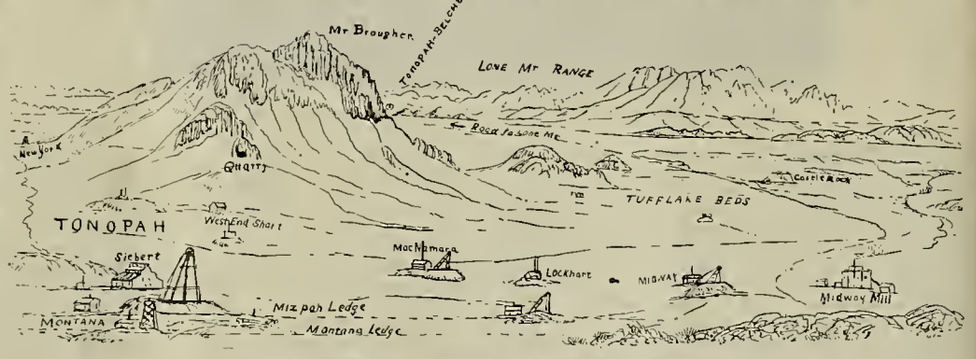
LONE MOUNTAIN.—On leaving Tonopah and going west we pass over a prairie-like region underlaid by thick beds of stratified volcanic tuff, which to an unknown depth overlies and obscures the ore-bearing andesites of Tonopah. This volcanic tuff, derived from finely comminuted material, shot up in the air from some of the volcanic vents in the vicinity, fell in showers upon the bed of a lake and was stratified by its waters. It contains occasional fossil imprints of leaves and terrestrial vegetation. Continuing west we pass occasional bluffs and tables of tuff capped with basalt. About 20 miles west of Tonopah is a group of hills around a central peak called Lone mountain. This peak is of massive granite, and against it recline, usually at steep angles, a thick series of uptilted slates, schists, quartzites and metamorphosed limestones, and marbles of Cambro-Silurian age, interpenetrated by sheets, dikes and intrusive masses of andesite and other eruptive rocks, the heat of which, doubtless, metamorphosed the sedimentary beds. The evidences of this metamorphic action are very pronounced — shales are changed into slates or schists, sandstones into quartzites, and limestones into white marble; while various minerals, characteristic of metamorphic action, appear in the rocks at contacts with the igneous dikes, such as epidote, which is particularly abundant. We have here all the acknowledged geological conditions for mineralization, nor are the precious metals wanting.

Near Lone mountain are the remains of an old arrastra showing that some primitive miners found gold and worked it. Numerous large fissure veins, striking about north and south from the peak, trav-

Loading Ore at the Tonopah-Belcher Mine, Nevada.



A Sketch of Tonopah-Belcher Mine and Vicinity, Lone Mountain, Nevada.



The Lone Mountain Range from Tonopah, Nevada.

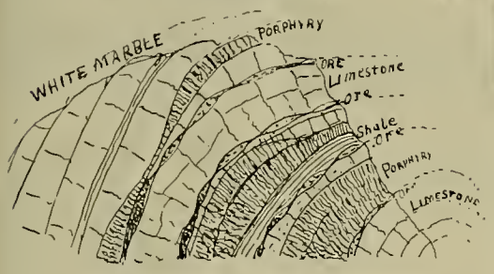
erse the volcanic rocks and the sedimentaries alike. These veins have as yet been little opened or proved, but they show on the surface unmistakable signs of mineralization.

At the Tonopah-Belcher mine, south of Lone Mountain peak, a long ridge called Belcher mountain is composed of tilted, or rather folded limestones, marbles and slates, with intercalated intrusions of

Cliff near Leadville, Colo., Showing Intrusion of Porphyry into Sedimentaries.

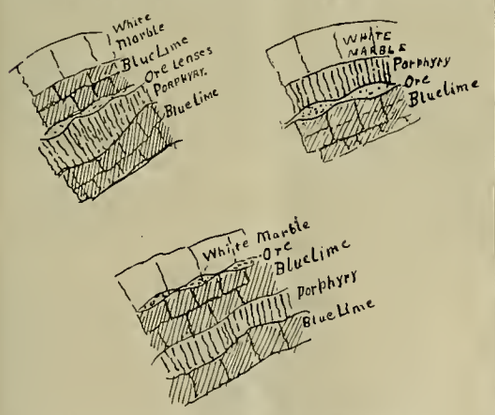
porphyry. The formations are very much like those of the Mosquito range at Leadville, Colo. In the limestones, and at their contact with the intrusive sheets, are lenticular bodies of carbonate of lead ore, carrying silver, lying more or less conformably with the stratification. The strata of the hill containing these ore bodies has been folded into an anticlinal arch which is truncated or dissected by the ravine running parallel with the hill.

Ore bodies are found outcropping and dipping into



Ideal Cross-Section of Belcher Hill, Nevada.

the hill apparently in three or four parallel zones. The degree of dip of these zones as they enter the hill varies according to the part of the fold the erosion has cut; thus at one place on the upper part of the ridge the ore zone enters the hill with a dip of not over 15°, and continues in for a few hundred feet till it becomes steep and goes down with the anticline; lower down the hill the next zone dips in at 25° or 30°, and the next below that at from 40° to 60°. All these zones will, with depth, become very steep or nearly vertical. The intrusions of eruptive rock are, as at Leadville, very irregular and hard to



Position of Various Ore Bodies in Belcher Mine.

follow or portray in a section with the present slight development of the mines. They appear as brown, lenticular masses, outcropping here and there at various levels on the face of the ridge. No one section across the face of the hill would show them all in their relative position. Sometimes they are below a certain well-defined limestone, again they are above it, sometimes they are at contact above the ore, and the ore lies between them and the limestone; at others the ore is above the porphyry and below the limestone, or again the ore may lie between a blue limestone and a white marble, and the porphyry be absent. The intrusions of porphyry appear to occur in tongues or lenses dodging about and insinuating themselves between the bedding planes of the strata.

The accompanying section of a cliff near Leadville, Colo., will exemplify the ramifications of intrusive sheets of porphyry in sedimentary strata, and in a manner very similar to that at the Belcher, to which it has a close analogy.

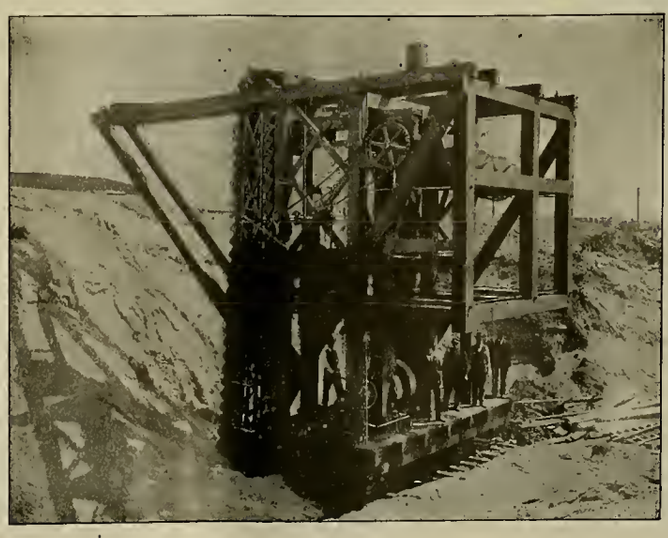
These intrusions, besides splitting open the strata, have locally faulted it. At one place a large massive intrusion of a peculiar variety of porphyry has come up and apparently deflected the strike of the limestones, bending them around at an elbow. At the sharp bend the strata have broken in a fault. The lenticular bodies of ore consist of masses of decomposed rock and iron oxide, mingled with lead carbonates, usually in the disintegrated form called at Leadville "sand carbonates." Mingled with these sand carbonates are abundant grains, kernels, nodules and small irregular bodies of galena, which are high grade in silver. The probability is that these scattered bodies of galena will increase in quantity with depth until the whole body becomes a sulphide, or a mass of silver-bearidg galena. It has been observed in other regions that these scattered nodules of galena are, near the surface, richer in grade than the galena body proves to be ultimately in depth. Whether or not the different zones of mineralization will, in depth, come together into one large body remains to be proven by deeper workings and crosscutting.

Carbonate of lead ores in large quantities are comparatively scarce nowadays, and, though low grade in silver, are much desired by the smelters to mix with their siliceous ores, such as those of Tonopah. They would be very valuable in case smelting works should be at any time erected in that camp, apart from the intrinsic value of the ores themselves with their lead and silver contents.

There are other promising mines and veins in this Lone mountain region of which no one can foretell the future. It will be observed that the Tonopah-Belcher ore deposits are entirely different in character from those found at Tonopah, as well as the rocks in which they are found. They remind one of the ore deposits of Leadville and Aspen, Colo., especially in the early days of those camps.

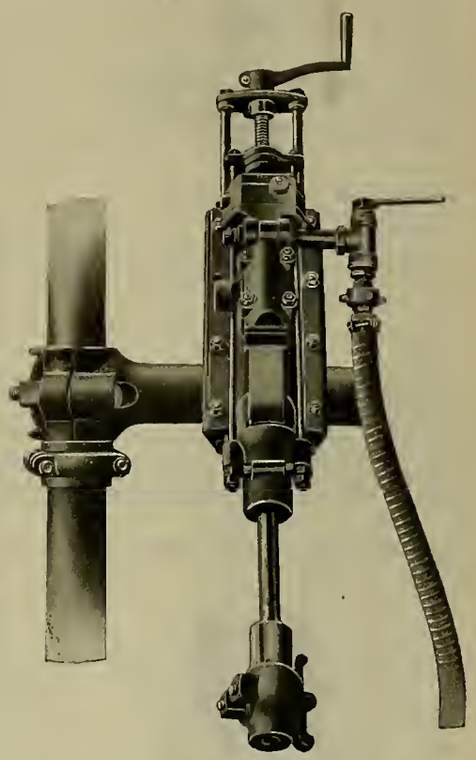
Sand and Gravel Digger.

Herewith is portrayed an automatic combined sand and gravel digger, elevator and grader, designed and constructed by the C. O. Bartlett & Snow Co., Cleveland, O. In operating the railroad track is laid along parallel with the bank to be excavated. The digging is done by heavy steel buckets, provided with special teeth, fastened to a stroug chain, all supported by a self-contained elevator leg pivoted at the head end, thus allowing the lower end to be gradually forced into the bank by means of heavy cables attached to the bottom of the elevator leg and running up over sheaves at the outer end of the projecting arm of frame, then down to a drum which is geared to the engine shaft. By this means the lower end of the elevator is to be gradually forced into the bank, digging and elevating the material up to an angle of 70°, commencing at the bottom and gradually digging its way up. The steel buckets are designed to dig the gravel, sand or other similar material and elevate it as fast as dug, discharging it at the top onto a belt conveyor, delivering it to a revolving screen on the opposite side from the elevator.



An Economical Device.

Herewith is illustrated a new "Economy" air cock attached to a "Giant" drill, the design being to obviate the loss of air due to leakage, and do away with constant leakage of air around the taper plug.



This air cock is so arranged that the pressure of the air on the bottom large end of the taper plug keeps the plug fittiug the seat, at the same time allowing it to be freely operated. To compress air is costly at best, and, it being desirable to avoid all leaks, this device is presented by its makers—the Compressed Air & Machinery Co., 24-26 First St., San Francisco, Cal.—as effectually preventing loss of air in the operation of rock drills.

The American Mining Congress.

The following preamble and resolution were passed by the board of directors of the American Mining Congress at its third meeting held in Portland, Or., March 21, 1904:

WHEREAS, Questions of great importance confront the American Mining Congress, and the correspondence and clerical work incident to carrying out the purposes of its organization have assumed proportions that justify and necessitate the acquisition and equipment of a permanent location to be used as the business headquarters of the Congress; therefore be it

Resolved, That a committee consisting of T. Ewing of California, D. Moffatt of Denver, Colo., and J. R. Leonard of Pittsburg, Pa., be, and the same is hereby appointed, with instructions to consider the following questions:

1. The most suitable and available locality for such permanent headquarters.
2. The amount of money necessary to acquire a suitable site.
3. The cost of constructing suitable structures on such site.
4. The expenditure necessary to properly equip such structures for the purposes intended.
5. The annual cost of maintaining such headquarters.

And to report recommendations thereon at the next session of the Congress in August, 1904.

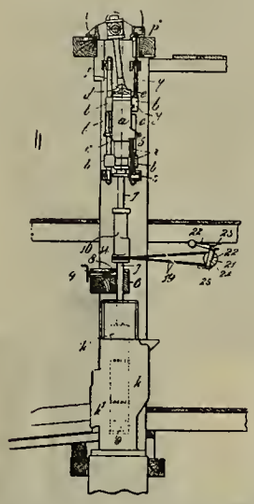
The next meeting of the American Mining Congress will be held in Portland, Or., August next, 23d to 27th, inclusive.

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 29, 1904.

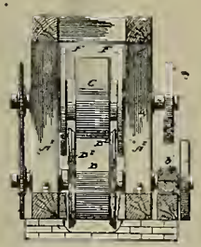
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

STAMPING APPARATUS FOR CRUSHING ORES, ETC.—No. 755,686; D. B. Morison, Hartlepool, England.



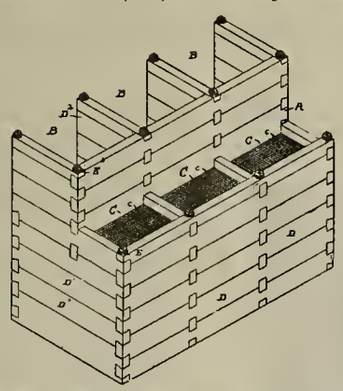
In stamping apparatus, combination with stamp stem of means for holding same in raised position comprising block of less width at bottom than at top, means for supporting block adjacent to stem but leaving it free to tilt, and means for moving block so that its wide part comes into contact with stem and for holding block in that position, but allowing it to tilt.

ORE CRUSHING MILL.—No. 755,725; E. A. Wall, Salt Lake City, Utah.



Combination with frame and lower roll mounted in fixed bearings therein, of upper driven crushing roll having free vertical movement toward and from upper side of lower roll, to crush material passing rolls, and independent driving means for rotating upper roll in opposite direction to lower roll and at same rate of speed.

JIG TANK.—No. 755,749; G. T. Cooley, Oronogo, Mo.

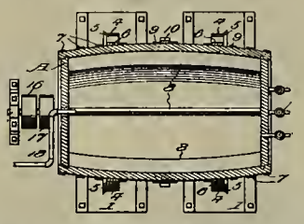


Jig tank constructed of separate side timbers, having interlocking tongues to form corner joints, tongues having one of interlocking surfaces beveled in planes of one of meeting sides and other surface beveled in planes of other meeting side, held together by draw bolts passing through tongues.

CONVERTING MATTES.—No. 755,557; R. H. Aiken, Jerome, Ariz.

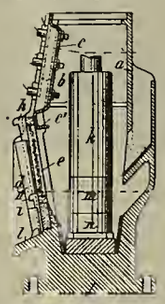
Process of converting mattes by subjecting charge of molten matte in a converter to an oxidizing blast, and meantime adding to charge, at rate approximately corresponding to rate of formation of oxide, material, proper for fluxing charge, at temperature approximately that at which slag forms from products of particular matte and fluxing materials.

APPARATUS FOR TREATING ORE.—No. 755,871; T. A. Helm, Salt Lake City, Utah.



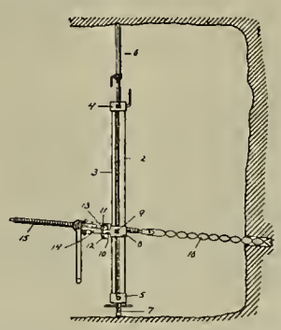
Apparatus for treating pulverized auriferous ores, comprising rotatable cylindrical tank, radially depending blades in tank extending length thereof, circular brace frame disposed between inner ends of radial blades, air pipe leading into tank, faucets to draw off liquid from tank, and means to rotate tank.

MORTAR BOX FOR STAMP MILLS.—No. 755,913; D. B. Morison, Hartlepool, England.



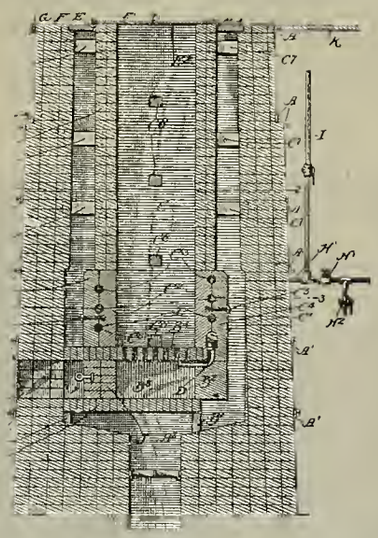
Mortar having two-part removable front, comprising lower screen section of usual design, and stiffened sheet-metal section detachably supported by box frame inside plane of screen, each section being independently removable.

COAL AND ROCK DRILLING MACHINE.—No. 756,028; L. K. Koontz, Allegheny, Pa.



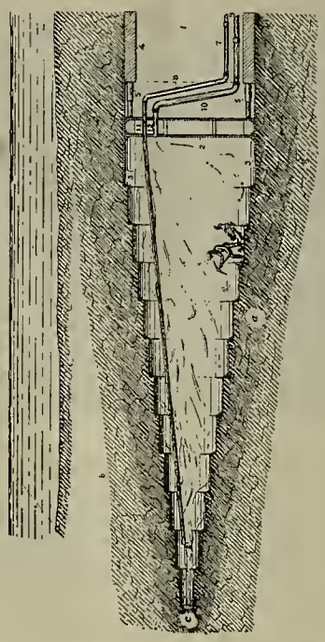
Supporting means for drilling mechanism, comprising vertically reversible post having separated uprights, and disconnected drilling mechanism sustaining devices, one on each post upright, each of devices having reversely disposed sustaining points.

METALLURGICAL APPARATUS.—No. 755,867; G. W. Gesner, New York, N. Y.



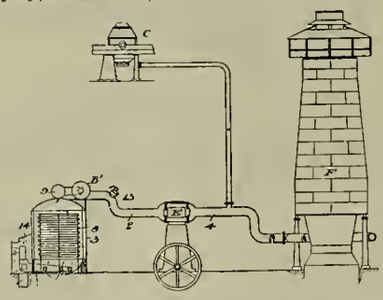
In apparatus for manufacture of alloy, or analogous use, combination of upright retort C surrounding flue and adjacent furnace arranged to discharge its products of combustion through such flue, pipe coil D partially exposed within fire brick to heat of flue, with open end of pipe discharging into retort, connection for introducing fluid to other end of pipe, chamber B^3 so material will descend by gravity from retort into chamber, provisions for opening and closing chamber, and grate B^4 of refractory material separating chamber from retort and tight floor B of refractory material separating chamber from furnace, arranged to allow descent of fine material only.

METHOD OF CONSTRUCTING TUNNELS, SHAFTS OR OTHER EXCAVATIONS.—No. 755,956; C. Sooysmith, New York, N. Y.



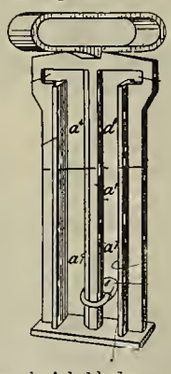
Method of tunneling which consists in constructing freezing chamber in material to be excavated, freezing surrounding material, advancing shield in rear of freezing chamber and completing tunnel lining.

METHOD OF EXTRACTING MOISTURE FROM AIR FOR BLAST FURNACES AND CONVERTERS.—No. 756,110; J. Gayley, New York, N. Y.



Method of feeding air blast to blast furnaces or converters, which consists in cooling air artificially, thereby causing its moisture to be reduced to small percentage, feeding dried air to blowing engine by initial pressure of relatively small degree sufficient to overcome in whole or in part friction of air current in apparatus, increasing its pressure at blowing engine to degree above that to which it was initially subjected and feeding dried air therefrom under compression into furnace or converter and maintaining it under compression from time it leaves the blowing engine until it enters furnace or converter.

FILE OR CARRIER FOR MINERS' PICK BLADES OR LIKE TOOLS.—No. 756,093; J. Beeton and J. Wardall, Hucknall, Torkard, England.



Carrier for miners' pick blades and other like tools consisting of body provided at one end with handle and at other end with base plate, body being formed with tenons or dovetails down and into which pick blades (having the usual recess) are adapted to slide and engage, and means for locking the blades in place.

Mining Summary.

Specially Compiled and Reported for the Mining and Scientific Press.

ALASKA.

The Rampart Forum says hydraulic plants will be large factors in the camp hereafter and Rampart will again add to Alaska's gold output. Rhode Island creek will be worked by hydraulic. Hydraulic apparatus is being put in by the Big Minook M. Co. More creeks are being worked in Rampart district than before this winter. The Glen district is said to promise well, with good outlook for Doric, Eureka, Thanksgiving, Omega and Gold Run. The Rampart side of the slope is also making satisfactory showing, with Little Minook, Little Minook Jr., Hoosier, Slate, Ruby and Hunker creeks being worked.

The J. G. Heid group of four claims on Windfall creek (the Examiner, Call, Chronicle and Free Press) have been sold to J. H. Conrad of Juneau and London, Eng., men.

The Pacific Steel Co. of San Diego, Cal., is reported to have bought 20,000 acres of coal land in southeastern Alaska. The coal fields are 15 or 20 miles back from Controllers bay, 70 miles west of the base of Mount St. Elias. On the property are said to be ten veins of coal varying in width from 4 feet to 28 feet of both bituminous and anthracite coal. About 20 miles of railroad will have to be built, but the loads will have a down grade all the way to the bunkers on the shore. The report is not verified.

A gold strike is reported from Eagle by C. M. Johansen, United States Commissioner. The find was made on an island in the Yukon river in front of Eagle. A shaft 45 feet deep was sunk and during the last 13 feet was in pay gravel. The bars up and down the river for a considerable distance from the island have been staked.

ARIZONA.

Cochise County.

The three Mitchson claims, 2 miles east of Gleeson, have been bonded to C. R. Bostwick for $50,000. One gold ledge on the claim is said to be 2½ feet wide and assays $20 in gold. The Copper Belle group, in the same section, has resumed operations, with sixteen men at work. M. Costello and J. Gleason are operators.

The smelter of the Copper Queen mine has been blown in at Douglas. The Copper Queen smelter has five furnaces with normal capacity of 500 tons per furnace. The Copper Queen mines at Bisbee are not expected to keep them all going to their capacity, but custom work will be done. The sampler is nearing completion. There is ore on the dump awaiting treatment and there are eight cars coming in daily to supplement this. A large supply of coke is on hand.

Gila County.

The Old Dominion C. M. & S. Co. has issued its report for year ended December 31, 1903, showing the following figures, in comparison with results for 1902:

	1903.	1902.
Gross receipts	$823,138	$883,378
Cost at mines and smelter	703,324	686,177
Freight, interest, taxes, etc.	112,083	130,559
Profit from production	8,729	66,641
Construction and development	10,720	72,179

There were smelted 57,210 tons of ore, from which were produced:

	Pounds Copper.
1,835,910 pounds of pig copper, at 95.03%	1,762,996
9,075,390 pounds of matte, at 62.99%	5,716,725
Total production	7,479,721

The directors' report says construction work will start this month on a concentrating plant, capable of handling maximum capacity of 300 tons per day. The company proposes to do custom smelting as well, and from time to time, as business warrants, enlarge the plant. The company during 1903 expended $476,640 in sinking the new shaft and in improvement of the plant. The production of fine copper was 7,479,721 pounds, as compared with 7,992,550 pounds during 1902. The production would have been larger but for shutting down of mine and limiting of output by reason of the flood. Aside from deficiencies of plant, which are being remedied, the only drawback to a successful operation of the property is lack of sulphur in the ore, says the report. Since October this defect has been supplied by ores bought from the Copper Queen Con. M. Co. of Bisbee; these ores have been delivered at works at a net cost of from $1 to $3 per ton. Since water in the mine was controlled and the Copper Queen ores secured, the property has been operated at a profit. The net profits from operations during October, November and December, 1903, were $94,000 (the net profit for January, 1904, was $21,000, and for February, 1904, $25,000). When the concentrator is completed it is expected it will not be necessary to buy any large amount of ores from outside sources. The total cost of production of fine copper laid down in New York was 10.90 cents per pound, and sold at average of 11.05 cents per pound. (The cost of refining pig copper into electrolytic copper is three-fourths of a cent per pound, and matte into electrolytic copper about 2½ cents per pound.) The following operating statistics are given:

	1903.	1902.
Yield of fine copper per ton ore smelted, pounds	130.74	116.10
Per cent of fine copper in ore smelted	6.54	5.80
Cost per ton ore mined	$7.72	$5.80
Cost per ton ore smelted	$4.58	$4.27
Gross amount realized per pound fine copper	11.02c	11.05c
Cost per pound mining and smelting	9.40c	8.59c
Cost per pound handling, etc.	1.50c	1.63c
Total cost per pound	10.90c	10.22c
Cost per pound copper for construction	0.15c	0.50c
Net loss per pound copper	0.03c	*0.24c

* Profit.

The plant account is increased $476,640. Of this latter amount, which represents construction during the year, $224,239 was expended at the mining plant and $117,626 at the smelter plant. The smelter was in operation 317 days. Opening and development work totaled 6556 feet. The present average daily production of the two furnaces is 60,000 pounds of copper for month of March. The output reached 1,500,000 pounds.

W. Webstor, who has a lease on one of the Cougblan mines, near head of Pinto creek, near Globe, reports getting out ore. The ore is covelite and runs 30% in copper. He has opened a streak of this ore a foot thick.

Graham County.

The New England & C. C. Co., near Clifton, is working twenty men. The tunnel driven to connect the New England and Copper King is in 1800 feet.

A working bond has been taken on a group of Frisco river gold claims, near Clifton, by a California company with W. Davis in charge. Development work is being increased.

Sale has been made to El Paso, Tex., and Colorado men of two placer claims, the San Jose and Catalina, on Eagle river, near Morenci, for $7000. E. Elsbaugh of El Paso, Tex., is manager. The claims are 2 miles from Eagle dam. It is intended to put in a 5 H. P. engine and pump for raising water from Eagle river to a tank on the hill and to put in sluice boxes as well as dry washers.

To decrease hoisting, it is reported the ores from the first level of the West Yankee mine, near Morenci, will be carried through a tunnel from the level direct to the sorting belt of the concentrator. This would not only relieve the hoist, but help out the bins. Timberers have finished the work of carrying the West Yankee shaft down to the breaking off level of the tunnel from the Old Yankee. Room is available for installation of an electric drill. This drill will drive from the West Yankee end to meet the men drilling from the Old Yankee to the shaft of the former. The sinking crew in the West Yankee shaft at the tunnel level will be increased and the shaft carried down 250 feet farther. It is now down 450 feet, all in ore. At 450 feet it is below the level of the Old Yankee tunnel.

The Cuprite C. Co. has been incorporated at Clifton by I. N. and C. E. Stevens, F. Alsdorf and F. B. Lane, to develop seventeen claims near Metcalf. The claims are joined on east by the Stevens C. Co. and south by the Santa Rosa Co.'s holdings. Ore has been taken from surface workings which gave smelter returns of 15% copper. The ore shows gold values. The lodes can be opened by tunnels which will give depth from surface of 800 feet. The claims are convenient to wagon roads and the railroad at Metcalf.

A. Lafave, who owns four claims at Gold Hill, near Metcalf, says on the Lady Mary claim he has crosscut the lead every 20 feet for 200 feet, and the ore averages 4 feet in width, assaying $15 in gold with some lead. He will drive a tunnel in on the lead lower down and proposes later to build a mill. He states there is sufficient water in the camp for two small stamp mills, and that more can be developed.

Maricopa County.

F. Webb of Tombstone reports sale of his bismuth mine to Manager Fisher of the Saxon Co. of New York. The mine is the Medicine Chief, east of Mesa. They have opened up a vein of bismuth ore 18 inches wide.

Mohave County.

Last week the Gold Road mine, near Acme, shipped a $16,000 bar of gold bullion, the result of one week's run of the Gold Road mill. The mill is shipping $70,000 in bullion monthly, which amount will be increased before fall. The lessees are keeping the mill supplied with high-grade ore. It is said the company proposes using wet crushing and installing electric power. At present there is not sufficient water to be had for all purposes.

C. L. Wilson has a lease on the Oro Plata, near Chloride, and has started work. On the O'Dea lease ore is being obtained. No water has to be handled by the lessees for some time to come. Three-ounce gold ore is being taken out and prepared for shipment.

A. H. Dryden, superintendent of the Altata mine, near Chloride, is working men on the mine and opening up bodies of high grade copper ore, says the Mohave County Miner.——A windmill has been put on the Towne mine at Chloride, says J. Barry, owner, to free the mine of water.

Pima County.

Silver ore is reported found 3 miles from Tucson. Wire silver is shown.

Pinal County.

The Phœnix & Eastern Railroad is opening up the mining sections of Pinal county. It is in operation as far as Florence and the rails have been laid a distance of 20 miles east of Florence. It is announced by the company officials that they expect to have the line completed into Dudleyville by July 1. The management has not yet decided whether it will go eastward from Dudleyville by way of Globe or by way of Willcox.

Santa Cruz County.

At the Mowry mine, near Nogales, additional boilers are being put in to supply increased steam required by the hoisting engine.——J. Bailey of San Francisco, Cal., has bonded four copper mining claims in the Santa Rita mountains for $20,000. The properties have considerable development work, showing high-grade copper ore.

The Chicago & Patagouia C. & G. M. Co., J. T. Brickwood, manager, which is operating the Old Soldier and Young Volunteer mines on the west side of the Patagonia mountains, 10 miles from Nogales, is increasing development. The main working shaft, going down to strike the ledge at depth of 200 feet, is down 80 feet. The incline shaft going down on the ledge 300 feet away is said to be developing an ore body.

Yavapai County.

G. B. Upton, manager of the Oro Grande M. Co., operating in Yavapai county, north of Wickenburg, says the test runs with the 5-stamp mill have proven satisfactory and the company is increasing the mill to ten stamps. To have sufficient water for the ten stamps it was necessary for the company to put in a pumping station in the canyon of the Hassayampa river and run a pipe line from there to the mill. From the pumping station to the mill is 1½ mile, but the water has only to be pumped under pressure for 1600 feet, raising the water in that distance 400 feet. From this point it runs to the mill by gravity.

G. P. Harrington of the Oro Bella mine, near Crown King, reports the mill idle on account of lack of water. A pipe line is being laid from the Tiger mine to the Oro Bella and is expected to be ready next week. The water will be pumped into tanks and then run by gravity to the mill, a distance of 2 miles.

L. N. Womhacher reports making a strike in the Cactus group of mining claims which he and H. Boyer are working. The Cactus group is the south extension of the Iowa group, 2½ miles from Cherry, near Dewoy. The strike was made at a depth of 250 feet. The ore vein runs 2 feet in width, assaying $100.

C. W. Platt, at Kirkland, says the machinery for the hoist of the Illizona M. Co. is on the ground and is expected to be ready to start next week, when work will be resumed in development.

L. Hall, manager of the Alma group at Groom Creek, says work on the group is progressing. Their tunnel is in 130 feet, and 30 feet more and a raise of 60 feet will make the connection for air. He says the ground is covered to depth of 2 feet with snow.

CALIFORNIA.

Amador County.

Manager P. B. Aiken says the mill at the Climax mine, east of Jackson, has not been running lately, due to lack of wood, the storm and soft roads preventing hauling. Meanwhile he continues development work and has uncovered a 9-foot ledge of ore.

Butte County.

In Bear canyon, 1½ mile northwest of Clipper Mills, G. Woolley & Bro. have located a quartz claim said to show values in sulphurets and free gold. The lode has been developed, showing 4 feet in width between walls. It is near the Bean quartz mine.

Calaveras County.

Manager J. Evans has fourteen men at work on the '49 and the Wild Goose mines at Douglas Flat. He sunk a shaft on the Wild Goose ground to depth of 150 feet, with a sump of 15 feet. Pumps and machinery were put in to handle the water. From the bottom of the shaft drifts were run and the pay channel has been opened up in the Wild Goose ground.

At Mokelumne Hill, C. G. Nuner and E. L. Burns have bonded the Guffra and Maloney mines and will reopen and develop them. There have been several shallow shafts sunk and short tunnels run on the two ledges. On the Guffra is a 10-stamp mill and hoist.

J. M. Evans has bought a large acreage of placer ground east of Vallecita, near Murphys, and will prospect the channels this spring. The mines at Douglas Flat continue developments, and the Texas shaft is being cleaned out in order for inspection.——W. B. Lake is arranging for opening up the Cataract and Wide West mines, near Murphys. A tailrace has been dug and the derrick is ready to operate.

Water power will be added to the mill at the Hercules mine on Indian creek, near Murphys. The present power used is gasoline.

The Calaveras M. Dev. Co. has been incorporated at Oakland to operate near Sheep Ranch by J. J. Fisher and R. R. Cunningham of Sheep Ranch and J. S. and A. H. Fox and J. J. Rignoy of Oakland.

Nevada County.

C. L. Canfield, operating the Canfield gravel mine at Blue Tent, near Nevada City, has a bond on the Grizzly Hill gravel property, on the Bloomfield road, 3 miles from Columbia Hill. It is said he will place a 10-stamp mill on the Grizzly Hill.

Operations will be resumed at the Rising Sun mine in Willow valley, near Nevada City. The property is under bond to G. Kartschoke et al, and they will unwater the shaft. During the summer machinery will be put in and the mine developed.

The property of the Green Mountain M. Co. near Grass Valley, including the Green Mountain, Centennial, South Centennial, Lizard, Wasp and Summit claims, has been sold to the Sultana M. Co., which will conduct operations. The company's main offices are in San Francisco, and J. M. and J. J. O'Brien, E. Schwab, W. C. Webb, W. S. Downing, E. B. Lillis and J. Garity are directors.

J. N. Davey and J. C. Menkel of San Jose have started work on the Piper gravel claim in Washington district to continue driving the tunnel. The tunnel, in 200 feet, is expected to strike the main channel within another hundred feet.

The Mountaineer mine on Deer creek, below Nevada City, is reported improving. The face of the 400-foot level which is being driven south toward the Summit location is said to be in ore that mills $17 a ton. The machinery handles the water notwithstanding the storms. Thirty men are at work, with J. C. Campbell as superintendent. The mill is in full operation.

A variable speed induction motor, using a 60-cycle, three-phase high-tension current, has been put in at the 1400-foot level in the North Star (incline) shaft, near Grass Valley, to operate a "five-throw" pump. When run at its full capacity of 50 H. P. it will lift the water 600 feet vertically at rate of 800 gallons per minute.

Operations will be resumed at the Red Cross and Huron mines at Omega, near Washington, by Davey & Menker, of San Francisco.

Operations were resumed at the Red Cross mine, near Nevada City, last week.——The stamps of El Oro mine, near Maybert, are steadily crushing ore again.

Operations at the Brophy mine of Shady Creek, near Nevada City, will be resumed this week, says Superintendent Miller.

The Murchie mill, near Nevada City, will be enlarged, says Superintendent Maltman, and he will add four stamps.

Placer County.

The Three Stars quartz mine at Auburn has been sold to E. H. Vance of Oakland for $25,000. B. F. Hartley is superintendent.

San Bernardino County.

(Special Correspondence).—The Copper World, the Vulcan and the Excelsior mines have been bonded to San Francisco men. These properties are near the line of the Salt Lake R. R., and about 35 miles northwest from Manvel.

The Trio C. Co. is operating mines in the New York mining district, 1 mile west of Manvel. It is owned by Pasadena men. The workings consist of a shaft 165 feet in depth on the ledge, showing copper ore. It is a contact vein, between lime and porphyry. The ledge is 15 feet in width, carrying values of 10% copper. Some specimens of native copper have been taken out. A drift has been run at the 150-foot level which cuts a shoot of ore 35 feet to the west. This shoot also shows in a shaft near surface 100 feet from present workings. A plant to reduce the ore on the ground is proposed. The mine

is 1 mile from the Santa Fe R. R. and 3 miles from the Salt Lake R. R.

The Giant Ledge Co. shipped a carload of ore last week to Canon City, Colo. This mine is 9 miles from Manvel and is expected to be put on the producing list this summer.

Manvel, April 5.

San Diego County.

O. H. and J. H. Schumaher and F. Kuhn of Fullerton have a bond on the Alamitos mine, in mouth of the Oroflamme canyon, near Julian, and will start development.

J. W. Wiley and M. S. Darling, operating at Palo Verde, are developing gold prospects consisting of a group of five claims. In sinking a 100-foot shaft they struck several pockets in free gold. The group is within 5 miles of the river valley, with plenty of wood and water available.

Shasta County.

In the proceedings instituted in the United States Circuit Court at San Francisco against the Mountain C. Co., Ltd., of Keswick, to enjoin that company from destroying the growing timber on the forest reserve near Keswick hy fumes from its smelters, counsel for the Government has withdrawn the application for an injunction pending suit "without prejudice until final hearing of tbe case on its merits is had." The copper company bas agreed to pay the Government for the loss incurred.

All five furnaces at the smelter of the Mountain C. Co. at Keswick are running. It requires forty men to run each furnace —twenty on each shift. The number of men employed at the smelter is not so great as it was two or three years ago, when the open-air roasters were used and when wood was used for fuel. The substitution of electrical power for steam reduced the working force at the smelter hy seventy-five men.

Sierra County.

J. Bothwell of Downieville has a bond on tbe Papoose quartz mine in Jim Crow canyon, and will put men to work next week.

Siskiyon County.

The Chinese Co., on China creek, near Yreka, has honded its mine, witb water rights, to T. J. Nolton. The water supply Nolton intends to put on tbe Williams Point mine.

The Scott Valley hydraulic miners in the Oro Fino, Quartz Valley, Mugginsville and Pinery districts, near Etna, have been troubled by the excess of water from the heavy rain of the recent storms, hut expect to get ditches fixed up this month for operation with giants and elevators. They also expect a longer season than usual, since the additional heavy snow storms in the high mountains.

Tehama County.

H. D. Lausen and S. Guidery of Oroville have hought a dredger mining property near Red Bluff.

Trinity County.

The Poker Bar Dredging Co., near Weaverville, will start operations next week. A large number of men will he put on and a new boat built.——La Grange M. Co. is piping out of its new reservoir and if weather permits expects to have same ready for use hy May 1st, says the Trinity County Journal. The only water available at present is that which comes through the West Weaver pipe line. Repairing of other ditches is going ahead.

Tuolumne County.

A concentrator has been added to tbe mill at the Soulsby mine, at Soulsbyville. ——The mill at the Duffield mine, near Carters, will hegin crusbing rock next week.——The mill at the Starr King mine near Carters has started up after a temporary shut-down.

The John Royal mine, on Knownothing gulch, near Columhia, is increasing development work.——Drifting on the vein while crosscutting in the Old Tuolumne mine, at Wet Gulcb, is going ahead.—— The Columbia marble quarry continues to ship usual quantity of marhle.——Owing to stormy weather, mining and milling operations at the Mapes mine, on Yankee hill, near Columhia, and also at the Mountain Lily mine, have been interrupted. ——The new shaft at the Over mine, near Saw Mill Flat, has reached depth of 95 feet.——Since setting up of the heavier boiler at the Altadena mine, sinking on the vein has heen resumed.

The Providence mine and mill near Carters are in full operation with forty men at work, says Superintendent A. Scott.

The O. K. M. Co. has taken over the Annie May, the Night Star or Garner mine, O. K. 2, Cracker Jack Nos. 1, 2 and 3, Anaconda, Sugar Loaf et al. quartz mines, 6 miles northeast of Groveland, together with buildings, millsite, tools and machinery.

The mill being built on the Republic mine near Parrott's Ferry, near Columhia, is nearly completed.

Yuba County.

Debris Commissioner W. W. Waggoner says the steam shovel is working at Daguerre Point and has been making good headway, considering the rains. The earth embankment at Barrier No. 2 has been washed away. The pile driver has been recovered and placed in position to continue the experiment of pile driving.

COLORADO.

Bonlder County.

Tbe Monarch Con. G. & C. M. & M. Co., which owns 1700 acres of copper prospects on the Roaring Fork, 8 miles west of Arapahoe Peak, has bought the Pilot and Little Gyp mines at Sunshine. The company has put on men to set up additional machinery, consisting of a hoisting plant, etc., to work both mines. On the Pilot the company has a vein 7 feet wide, said to run $20 per ton in gold.

J. Yates, J. Criss and C. H. Wise of Boulder have a lease on the Herald mine, in Sugar Loaf district, and will develop it. The Herald is a gold property.——At the Nancy tunnel, at Wall Street, Manager W. Mitchell says be is putting in extensive improvements in the mill at Wall Street. They are also putting in a compressor and propose to develop the tunnel.

Chaffee County.

(Special Correspondence).—The Atlantis group of eight claims is heing prepared for spring work. Ore shipped from four of these claims is said to have run $96 per ton. There are tunnels on the claims from 250 feet to 400 feet in length. The ore carries gold, silver, lead and copper values. They are preparing to stope in the tunnels. H. Dyatt, of Leadville, is owner and expects to put in a water power plant and mill. The mines are 18 miles south of Leadville.

Granite, April 3.

The West Gold Hill M. Co. has prepared plans for a 50-ton cyanide mill to he built on West Willow creek, near Buena Vista, this season. The ore is said to carry an average value of $10 a ton, which can be recovered by the cyanide process at a cost, including mining, milling and tramming, not to exceed $2.50 per ton. The company has heen increasing work on the Sellers claim all winter and followed tbe ore 200 feet in the lime. Porphyry contact has been struck. A winze is being sunk in the floor of the drift to determine the thickness of the ore body below. It has heen crosscut for a lateral distance of 21 feet.

Clear Creek County.

The Empire Tunnel Co., owning the Tenth Legion mine, near Empire, is arranging for extensive development work. The Empire Tunnel Co. among its holdings in the Empire district has the Gold Dirt mine, also, from which shipments to the smelter have heen increased. Provided arrangements can he made with the mills, a heavier tonnage of mill dirt will be sent out. An output of thirty tons of concentrating ore can be made daily.

On the Magnet mine, near Georgetown, a whim has heen set up to hoist rock and mineral. A drift has been started west on 8 inches of ore, which mills 300 ounces in silver per ton.——Exploration is being carried on in the Mascot group, owned and operated by H. Jacoby, to open up ore reserves.——The Annetta M. Co. is sinking a winze from the tunnel level of the Griffith vein. It is down 90 feet, and has in the hottom 2 feet of lead ore, which carries an ounce in gold per ton, with silver values. In the hreast of the level going east is a body of quartz, witb 18 inches of ore, assaying $40.——Maxwell & Hood have started to drift east on the portion of the Griffith vein owned hy them.

Manager Cooper of the Capital Prize M. Co. has, after a temporary shutdown for repairs, resumed operations near Georgetown. The ledge bas been opened by a crosscut and shows bodies of iron ore impregnated with lead, with silver values and gold.——S. D. Farout has a lease and hond on the Sanora vein on Griffith mountain. He will consolidate the property with the Lafayette group and increase development during the summer. There is said to be 4 inches of ore to start on, which runs well in silver.——Drifting continues on the King William lode through a body of mineralized quartz. The work is heing done by contract under supervision of C. H. Morris. The property adjoins the Anglo-Saxon, Pickwick, Magnet, Mascot and Summit.

Custer County.

The Bassick G. M. Co. near Silver Cliff is preparing to lease twenty-six blocks of its holdings. —— After an extended idleness the Toledo mine is again in operation and mine work is in progress, with two shifts. The shaft is 200 feet deep, hut will he sunk at least 300 feet deeper. ——H. Hendershot is working the Protection and Suicile mines under lease and bond, and in development work high-grade ore has been taken out. Stringers of silver ore are being mined. The vein is 5 feet wide. A shipment of 1800 pounds to the Pueblo smelters returned 119 ounces of silver, 4% copper and 8% lead. Hendershot is running a drift on the vein. ——Preliminary work at the Valley mine is in progress by lowering the water. As soon as this is finished the company will sink and drift on the vein.

Fremont County.

E. L. Bettis, at Canon City for Eastern men, has taken over a group of claims carrying a ledge of marble, near Cotopaxi, in western part of county. The marble, it is said, is suitable for statuary.

Gilpin County.

During the month of March the shipments from Quartz hill mines, near Central City, of the Kansas-Burroughs Con. M. Co. amounted to 125 cars, or 1100 tons, most of which went to the mills and concentrators, a small percentage going to the sampling works.——Mitchell & Sons of Central City will put in a steam plant on the Gulch mine in Lake district. They bave it developed to a depth of 290 feet, hut have suspended operations on account of the slow work of hoisting from that depth with a whim hoist and horse. Tbey have shipped considerable milling ore, as well as first and second-class smelting ore. ——G. W. Mahee Sr. of Denver has started up the Newfoundland mine, on Gunnell bill, after overhauling the machinery and buildings and unwatering the incline shaft.

Gunnison County.

The Yellow Coin G. M. Co. has been incorporated by J. S. Woodruff of Denver, H. P. Woodend of Loraine, and others, to operate at Bowerman. It owns eleven claims on South Copper mountain, near the Kuenz group.

Hinsdale County.

The Golden Fleece mill, near Lake City, is in operation by Kilvert & Watkins.—— L. A. Vinton in Horseshoe hasin has resumed development of the Puzzle claim. ——Superintendent H. H. Lynde, for La Belle M. Co., is putting in 80 H. P. hoiler at La Belle tunnel.

Lake County.

(Special Correspon ence).—T. Fain is leasing on the Benton mine, on the west end of Breece hill, and reports striking ore.——Adamson & Co. are leasing on the Little Pittshurg, and are operating on shaft No. 11, which is down 90 feet.

Leadville, April 2.

(Special Correspondence).—W. S. Jones, manager of the Cloud City mine, has the shaft down 500 feet and will sink 125 feet deeper. This company has fifty acres and a lease from the city to mine under tbe streets. A hody of ore was struck in the lower level last week. The ore is iron oxide, with sand carbonates.

Leadville, April 3.

The North Moyer shaft at Leadville, put in operation in January, is taking out good grade of iron sulphides, says the Carhonate Chronicle. The output of the Moyer and North Moyer shafts is 4800 tons of zinc ores, 1000 tons of zinc-lead ore, 4000 tons of iron sulphides and considerahle copper-bearing iron ores. About 2200 tons of the zinc is milling ore. The principal portion of the zinc ore comes from the Moyer shaft which is working three levels, the lowest being 480 feet below collar of shaft. The iron and copper ores come from the North Moyer shaft, which is working about same deptb.

The Yak Tunnel Co. at Leadville is developing the Tankerstown, nortb of the tunnel. Tbe Tankerstown property is a mile from mouth of tunnel. A raise has heen driven 100 feet and a hody of low-grade sulphide ore opened from which shipments have heen made. Tbe ore carries silver, gold, lead, iron and zinc. The Yak Co. is also taking out ore from the Silver Cord mine.

The present daily output of Leadville district is over 2500 tons of all classes of ore. The producers in the older territory are doing well, as are a number of suh-districts, which are sending daily shipments. This output is steadily growing. South Evans, Big Evans, Fryer, Carbonate, Breece and Rock hills, Iowa and California gulches, all near the city, and St. Kevin, Half Moon, Twin Lakes, Sugar Loaf and other outlying sections are adding to the daily production.

The Midas M. Co., which controls the Colorado and Penrose ground at Leadville, has remodeled and retimbered the latter shaft. They are ready to get pipes and machinery in place, so that sinking can resume hy May 1. The pumping plant of four boilers and one main pump will cost about $27,000. The pump will have capacity of 1500 gallons per minute, and raise the water 1200 feet.

At the Golden Curry mine, near Leadville, G. Nestor & Co. report a find made in a tunnel run in 500 feet, and the ore shows sulphides averaging $25 a ton. In the hreast of the tunnel a body of ore has been opened up, wbich shows average assays of seven ounces silver. Additional work is planned for the summer, including the sinking of a shaft, which is going down to cut the ore in the tunnel.——A lease has been granted on the Gertrude, near the Curry.——Ore is being mined by J. McNeece on his Fortune mine, while the lease on another part of the ground is being worked by T. Raney.——Some shipments of fair grade ore have been made from the Reindeer during past two months, but principal attention is being given to development and prospecting work. This is the shaft sunk on Rock hill.

T. Goodwin, manager of the New Monarch group at Leadville, and the Ohio & Colorado - Salida smelter, says that at both Salida and Leadville they have plans under consideration for improvements. The deepening of the Monarch shaft from 700 to 2000 feet will be put through and the plants of machinery on the ground will he put in place as soon as the weatber permits. As Manager Goodwin wants to handle the low grade as well as the higher grade material as the product is mined, the company proposes build ing a concentrating mill at the Monarcb ground. The strike in the Cleveland shaft is a hody of sulphide ore. The first work on the Monarch shaft will be retimbering tbe 700 feet tbat bave already been sunk, after which the plant of machinery will be put in place and the shaft sunk to 2000 feet or deeper. The Salida smelter, says Goodwin, is running full force. The capacity of the plant will be increased. The Ohio & Colorado Co. also has under consideration the building of its own refinery.

Mineral County.

The general mining outlook of Creede district is reported showing improvement over corresponding period of last year. All the mines are increasing output. The Humphreys company is producing 10,000 tons of ore per month, 6000 tons of which are concentrated hy tbe Humphreys mill, into 1000 tons of lead and zinc concentrates.——The United Mines, whicb is the principal property operated by this company, continues to show improvement, as development progresses, especially in the north end, says Manager G. Davis. ——Tbe Nelson tunnel has resumed work, driving the tunnel north through tbe White Star Co.'s ground, which is under lease to the Little Kanawha Leasing Co., controlled by A. E. Humphreys et al. This contains bodies of low-grade lead and zinc ores similar to that of the United Mines.

Park County.

(Special Correspondence).—H. Dyatt, of Leadville, is operating on the Peerless-Maude and adjoining properties. He is shipping ore that averages 40% lead. Part of the ore is concentrated 2 and 2½ tons into 1 and the high-grade smelting ore is shipped direct to the smelter. Plans are under way for working the group on larger scale. A mill is proposed.

B. S. Schlessinger, manager of the Last Chance mine and mill, expects to increase the output of his mine the coming summer. His mill is handling ore from the Peerless-Maude mine.

Doran, April 3.

Pitkin County.

(Special Correspondence).—Fire in the Smuggler mine still hampers progress underground. They are mining about 10,000 tons per month, which goes through the concentrating mills, and the concentrates are shipped to the smelters. They are running one of their mills twelve hours and the other twenty-four hours per day. Ore is concentrated 6 to 7 tons into 1. They are shipping 200 tons of ore each month in addition to the concentrates. The company employs 200 men. It is thought that 2 feet of bituminous shale on the hanging wall between the harder shale and the vein, which contains oil, is burning and causing the trouhle in the mine.

Shipments from all sources amount to about 12,000 tons per month from the district. The base of the ores of the camp is lime and the smelters pay for lime. The railroads have made graduated rates according to the value of the ore. Little prospectiug is heing done in the district, owing to the fact that the camp produces nothing hut silver, and at the present price of silver it will not pay to prospect for the same.

The Smuggler Co. has a lease on the Mollie Gibson and Della S. mines, which they are working.

Aspen, April 4.

San Juan County.

The Highland Mary tunnel, near Silverton, is in 5300 feet. Near the face of the tunnel is a raise of 400 feet, which connects with other workings including two drifts, one running north and one south from point of intersection. Gray copper carrying silver values is heing hroken from the

north drift. The concentrating mill of the Gold T. & R. Co., which owns the group, is in operation.

San Miguel County.

The Butterfly-Terrible G. M. Co., at Ophir Loop, is increasing operations on its group of mines. For lack of water, only twenty-five of the thirty stamps in the milling plant are dropping. The mill is handling 100 tons of ore daily. Manager J. F. Keating says during the fifteen days of March the amalgam and concentrate product obtained more than paid cost of operating the property for entire month—about $6000. In the mine, stoping has begun on the block of ground between the first and third levels, which is between 750 and 800 feet in length by 320 feet in height. The vein ranges from 1 to 8 feet in width. A tunnel will be started this summer lower down the mountain which will tap the vein between 500 and 600 feet deeper than the third level. It will be necessary to drive it 3000 feet before cutting the vein.

Summit County.

W. Lennox, M. Evans, et al. have incorporated the Lincoln G. M. Co. to operate the Goldrick (Clark-Riethmann) group in French gulch, near Breckenridge.——The West Side (Engle) mill is running steadily on Gold Dust-Puzzle ore, and concentrates are being turned out. Several four-horse teams are hauling ore from the mine to the mill. The Puzzle Leasing Co. is operator.

Work on the Admiral mine, below Wheeler, is progressing. The Admiral Co. is building a dam below the old site and is preparing for increased hydraulic operations this season.

Teller County.

The treatment rates on ores from Cripple Creek district have been reduced by the American R. & S. Co. and the United States R. & R. Co., and the Telluride mill at Colorado City. The rates being offered by these plants are as follows:

Treatment and freight on one half ounce gold ore	$5.50
Treatment and freight on one-half to one ounce	6.00
Treatment and freight on one to one and one-half ounces	6.50
Treatment and freight on one and one-half to two ounces	7.00
Treatment and freight on two to three ounces	8.00
Treatment and freight on three to five ounces	9.00

All values over five ounces $6 for treatment with freight charges added.

To show the extent of the cut the previous scale is given:

Treatment and freight on one-half ounce	$ 7.50
Treatment and freight on one-half to three-fourths ounce	8.25
Treatment and freight on one ounce	9.00
Treatment and freight on one and one-fourth ounces	9.25
Treatment and freight on one and one-half ounces	10.50
Treatment and freight on one and three-fourths ounces	11.25
Treatment and freight on two ounces	12.00
Treatment and freight on three ounces	12.75
Treatment and freight on five ounces	13.50

Negotiations are under way for building a cyanide mill on the ground of the Isabella G. M. Co. at Cripple Creek. They propose to buy the dumps at the several mines on Isabella territory.

J. H. Featherstone has a lease on the entire workings of the Dillon mine on Battle mountain, near Victor, which adjoins the Portland mine. He is working from the third level up. Lessee Featherstone has subleased the fourth and fifth levels to Gorman & Co., who have opened a streak of ore from which they made first shipment this week. The sixth level it subleased to the Victor Leasing Co. The seventh and eighth levels are subleased to Moore & Co. The latter is making preparations to do a large amount of development work. They are building an ore house with capacity of 100 tons.

The ten lessees on the Doctor-Jack Pot holdings at Cripple Creek shipped out during March twenty-five broad-gauge cars of ore, with average values of $35 in gold per ton. All of the ground of the Doctor-Jack Pot Con. M. Co. is being operated by lessees.——Superintendent E. G. Taylor of the C., K. & N. mine, on the western slope of Beacon hill, says the mine produced during March 860 tons of ore, giving average values of $65 gold per ton. Taylor, who has charge of the Old Gold, adjoining the C., K. & N. on the south, as lessee, says the Old Gold output 1700 tons of average value of $35 per ton.

The Vindicator M. Co. at Independence shipped out during the month of March 1200 tons of ore, giving an average return of $50 gold per ton. The ore is being mined from above the tenth and below the sixth levels. The management is making no attempt to get below the tenth level, which is flooded with water.

M. Burke, who struck ore on the Henry Adney claim on west slope of Beacon hill, Cripple Creek, is cutting a station at depth of 416 feet. When this work is done and additional machinery set up shipments will be started. The ore house capable of handling 100 tons of ore per day is completed. The shaft house is also finished. A 10x12 hoist with engine and 80 H. P. boiler is going in. Burke holds bond and lease for $35,000.

The Old Gold M. Co. is putting in a plant of machinery and an air compressor preparatory to working a property on Beacon hill, Cripple Creek, on company account. Lessee Taylor & Co., who was operating under lease, made good tonnage of ore, returning values of $60 per ton. The ore was being broken in a drift 180 feet southwest of shaft at depth of 390 feet from surface. His lease expired April 1.

The water in the shaft of the Mary McKinney mine at Cripple Creek is receding at rate of 2 feet a week, due entirely to El Paso drainage tunnel. By May 1 the company will have drained all the water from the sixth level. The company is receiving large number of applications for leases, but at present not many are being granted.

IDAHO.

Ada County.

G. A. Tuttle, manager of the Copper Mountain M. & M. Co., operating at Copper City, 8 miles from Eureka, reports the new boat for the Snake river will be running by May 1. His company, in which Spokane, Wash., men are interested, will start shipping as soon as the boat runs. They are working fifteen men and will increase the number. The smelter at Eureka will start up this summer. The Copper Mountain ore will be shipped there. The mine is near the river, so that a tramway will be put in to load the ore on the boats. They will also put in hoist and electric drills this summer. The Electrolytic mine, which adjoins, is working a few men.——A deal is pending for the sale of the Yellow Boy mine, owned by Smith & Woodrum of Lewiston, Idaho, to Eastern men for $60,000.

Shoshone County.

The Little North Fork C. M. & M. Co., Ltd., is increasing development of its copper mine, near the Little North Fork. The drift is being run to catch the ore shoot that was cut above. This is in 425 feet and is expected to reach the shoot within 100 feet farther. The owners are P. Anderson, J. Brandon, B. Teckham, Matchette & Mason and G. W. Harris of Wardner.

The Hecla M. Co., operating the silver-lead mine near Mace, is shipping its ores to the Salida smelter in Colorado, where they are fluxed with local siliceous ores. The Bunker Hill & Sullivan is out of the smelting company's control. The Cœur d'Alene Dev. Co., which formerly supplied considerable tonnage from the Crown Point group, near Wardner, is practically closed, and is only getting out a little ore under lease. The American S. & R. Co., says the Spokesman-Review, is holding the Federal group under long time contracts, and is getting the output of the Last Chance at Wardner, the Mammoth and the Standard at Mace and the Tiger-Poorman at Burke, together with the ore the Tiger-Poorman at Burke sends out. It is also getting the tonnage from the Morning mine at Mullan. This year is improving for the Cœur d'Alenes. The output is large and the price of lead up, while the labor question is quiet. In addition the railways are reducing rates for transportation of ores to the smelters. Another cut was announced last week to Leadville, Colo., over the Northern Pacific on ore or concentrates from Mullan, Morning, Wallace, Sunset, Manchester, Gem, Frisco, Mace, Hecla, Burke, Osborn and Wardner. A rate of $7 is offered for ore worth not more than $60 a ton, $9 for ore not over $65 and $11 a ton for ore worth less than $100 a ton. To Denver and Pueblo, Colo., the same grades of ore have rates of $8, $10 and $12, respectively. The minimum carload will be 30,000 pounds.

According to reports of the employment office of the Mineowners' Association, 75% of the 2000 miners engaged through that agency in the Cœur d'Alenes are native-born Americans, while all the foreign-born element employed have declared their intention of becoming citizens of the United States. Before a man is able to obtain a position through the employment agency, it is necessary for him to submit satisfactory proof to those in charge that he has declared his intention of becoming a citizen. In the mines of the association above Wallace, 1100 men are employed, and of this number 26% are Missourians. These 300 miners are nearly all working in the Standard, Mammoth, Hecla and Tiger-Poorman mines. Formerly there were some employed at the Mullan and Wardner mines, but few, if any, now. Of the foreign-born, Swedes constitute 10%. They are principally at the Morning mine at Mullan. Finlanders compose about 5% of the total number, and are mostly in employ of the Morning Co. These two comprise one-half of employes at the Mullan property. Among the remainder there is a mingling of nationalities scattered in the different mines. Coruishmen form a large portion of the employes in the Bunker Hill & Sullivan mine at Wardner.

A final settlement of the 16 to 1 mining case has been made and operations resumed. The 16 to 1 mine is in Nine Mile section, near Wallace. On account of the heavy snow in that section, the work of opening up the mine will not be started until May.

MISSOURI.

Jasper County.

The Ozark Zinc Oxide Co. at Joplin is enlarging its plant for the second time. The capacity will be increased by one-third when the new furnaces are ready for operation. Last year the capacity was doubled. A building of brick and sheet iron is being put up for the additional machinery. The product of the plant (zinc white) is used in manufacture of paint. The company is smelting carbonate ores from Mexico, New Mexico and other Western points, as well as all the carbonate output of Arkansas.

MONTANA.

Beaverhead County.

At the Ajax mine, near Dillon, Superintendent Noyes has thirty men at the mine and mill. A mill, with ten 1050-pound stamps, has been put up and is handling twenty tons of ore per ten hours, which constitutes a shift. It is equipped with two tables which save a ton of concentrates per day, which, when shipped, net $25 per ton.

Cascade County.

Four feet of high-grade gold ore is reported found in the mine of the Crevasse Mountain M. Co., at Crevasse, by W. G. Conrad of Great Falls, part owner. The number of men at work will be increased.

Choteau County.

At Havre the Blackfeet Oil Land & Development Co. has been organized by J. S. Almas, L. K. Devlin, J. W. Huse, E. V. Hauser, M. Clark and W. C. Broadwater. The company will develop oil lands, of which it has 3000 acres, on Two Medicines creek.

Fergus County.

At Great Falls F. Longstaff, O. P. Perry, D. L. Williams, J. R. Mettler, O. F. Wadsworth, W. Ellis, J. A. Ferguson and J. Burns have organized to develop a group on Sage creek, near the Cascade county line.

The Little Hazel M. Co. is driving a tunnel 700 feet on the Little Hazel group in Conklin gulch, near Lewistown, for tapping a vein of silver-gold-copper ore exposed in a discovery shaft above. C. Edwards of Gilt Edge is foreman. The vein on the Little Hazel shows 20 inches of ore, carrying shipping values. The tunnel is in 175 feet.——C. Stephens of Cone Butte is driving a tunnel on the Alma and Alder. He has a 7-foot vein of ore that carries gold values of $7 per ton. The tunnel is in 110 feet.

Jefferson County.

The Cataract C. M. Co. is working full-handed at its Bullion, Crystal, High Ore and Grey Eagle mines, near Basin, until the smelter is running.——The Pennsylvania-Montana M. Co., operating the Hattie Ferguson mine, has put on more men and is shipping two cars of ore per week to east Helena.

The Red Bird M. Co. has put machinery on the mine it has under hond in High Ore gulch, near Basin. It is preparing to increase development and is shipping ore.——The number of men at the Hiawatha has been increased and a tunnel is being run on the west side of the hill to tap the lead and to facilitate the working of the mine, as it will make the haul easier, grade and distance being reduced, says Manager Dowling.

Work will be resumed on the Boulder-Comstock mine, near Basin, the company intending to put in more machinery and thoroughly develop the ground, sinking the shaft several hundred feet deeper.——The Basin Reduction Co. has started work on the slum dams below Basin, and, on the completion of these, operations will be started on the proposed enlargement of the concentrator to 2500 tons a day, the present capacity being 1500.

Park County.

H. B. Edwards, manager of the Ethel May G. M. Co. of London, Eng., which owns mines in Emigrant gulch, near Livingston, says he is preparing to put in twelve stamps having quadruple discharge mortars. Other machinery for use in the mill includes a Blake crusher, with capacity of 150 tons per day, and six Frue vanners.

The trouble between the Kimberley-Montana G. M. Co., operating the Bear Gulch and other mines at Jardine, and its employes has been adjusted.

Powell County.

G. J. Kirby, president of the Montana United M. Co., at Emery, says Superintendent Cohh is putting in a sawmill outfit for the mines.

Silver Bow County.

A strike is said to have been made in the Combination mine, in Meaderville, near Butte, last week. Development work has progressed to the 700-foot level and the find was made at that depth. Samples assayed 31% copper and 100 ounces in silver. Considerable water has been struck and the extent of the discovery cannot be ascertained until the mine is pumped out.

Teton County.

The St. Mary's Lake L. Oil Co. of Great Falls has been incorporated by I. Myers, C. M. Webster and R. Cooper of Great Falls to develop oil lands in northern Montana.

NEVADA.

Esmeralda County.

The Red Top M. Co. has been organized at Tonopah to operate a group of claims in Goldfield district. The officers are C. D. Taylor, F. M. Ish, R. L. Colborn, J. B. Menardi and G. B. McClelland. Colborn reports that a new lead has been found on the Vindicator group and preparations are being made to sink on it.

The Blair interests at Silver Peak are preparing for an increase of development work in the mines of that estate. The mill has been put in order. The mine is equipped with a 30-stamp mill and a leaching plant.

Lincoln County.

B. Macready, with Los Angeles, Cal., men, has a bond on the Forney & Hilbish group comprising five claims south of the Spokane group of the Southern Nevada M. Co., near Searchlight. He has put men on surface work prior to beginning development. Macready has also bought the Barney Reily mine. The claim is a fraction between the Santa Fe and the Miess group.

J. McArthur and F. A. Ray have a bond on the Confidence mine in the Summit Springs section, near Searchlight. Development work was begun last week.

The Nevada Keystone M. Co. will leave Sandy and move its mill to the mine near Sandy, says the Searchlight. The water supply will be pumped to the mine from Goodsprings. It is also reported the company intends making other improvements. The company will build at a point on the Salt Lake Railroad route, 12 miles from its mines, an electric plant with capacity sufficient to furnish light at the mines and power for operation of mining and reduction machinery. When the plant is set up the company will amalgamate forty tons of ore per day and cyanide fifty tons. Present operations are confined to milling high-grade ore (over $30 per ton).

Lyon County.

The North Rapidan mine at Como, near Dayton, is being prepared for a season of development work. The mill has started up.

Nye County.

J. C. Gladden and J. R. Walker of Salt Lake City, Utah, have bonded a group of seven claims 8 miles northeast of Crow Springs, near Tonopah. The ledge is said to show an 18-inch streak of silver-lead ore carrying shipping values.

Storey County.

Superintendent J. R. Ryan has arranged the pumping system at Con. Cal. & Virginia combination shaft at Virginia City, so that two Reidler pumps do the work formerly performed by three. This leaves one Reidler always ready for use in case of break-down, says the Territorial Enterprise. Two Reidlers and No. 2 elevator hold the water below the 2350-foot level.

Washoe County.

A 3-stamp mill will be put in at the Ninth Crossing mine, in Rainbow district, by C. F. Kolster and J. Urban of Reno. Work will be started this month and development underground will at the same time be increased.

A strike is reported in the Desert King mine, 4 miles from Reno, showing ore running $100 a ton in a 4-foot vein. The ore shows values in chlorides, free gold and wire silver. In character it is a breccia.

White Pine County.

J. B. Fleming of Salt Lake City, Utah, of the White Pine C. Co., operating at Ely, says the mine will be equipped with reduction works.

NEW MEXICO.

Grant County.

Machinery for the International mill is on the ground at Malone and is being placed.——The Owen Bros. have a lease and bond on the Bellum claims at Santa Rita.

The Con. M. Co. has bought the Chi-

cago mill at Gold Hill and it will be moved to the mines of the company near Lordsburg.

The Shamrock smelter at Pinos Altos was again blown in last week by Manager B. Johnson of the Burro Mountain smelter, who has the Shamrock smelter also. The copper matte from the Pinos Altos plant will be used for fluxing purposes in the Burro Mountain plant, as it contains iron and sulphur, carrying copper with gold and silver values. A flow of water has been obtained in Dead Man's gulch, half a mile below the Burro Mountain smelter, at a depth of 20 feet. This gives the company a flow of 1200 gallons a day, which is sufficient with the condensers that have been put in. However, several more wells will be sunk.

Rio Arriba County.

Tres Piedras reports say a strike has been made in Bromide camp on the 300-foot level of the Tampa mine. Only one shift is being worked. The vein is 12 feet wide and it is expected a mill will be built, says F. Bolton of the company.

Sierra County.

A deposit of platinum ore (sperrylite) is reported found 3 miles from Hillsboro. The ore is said to carry 3% of platinum. A vanadium deposit exists in three mines which have been opened up in several places, said to have given returns of 12% venadic-pentoxide. The properties are owned by W. Buchanan, J. H. Bigelow and S. J. Macy. It is proposed to increase work. —— Fourteen men have been put to work on the Empire mine, near Hillsboro, by the Empire G. M. & M. Co. The 200-foot station will be reached this month. The Empire has 2 feet of ore that runs $30 a ton in gold. —— The Bigelow G. & C. M. Co., operating near Hillsboro, will connect its two shafts, 400 feet apart, by running a drift each way on the 180-foot level.

Socorro County.

E. Craig is preparing for resumption at the Last Chance mine and mill at Mogollon. The mill is being overhauled and will be increased in capacity.——A deal is said to be pending for the holdings of the Helen M. Co. at Graham and the Confidence mine at Mogollon by English parties.

OREGON.

Baker County.

J. Mikel says he is arranging to open up the Nine Strike mine in Cracker Creek district, near Sumpter.

The I. X. L. mine, near Greenhorn, is preparing to sink from 200 to 300 feet deeper the coming season. The capacity of the mill will be doubled and other important improvements made, says G. A. Carter of Greenhorn, consulting engineer.

A. B. Patterson, superintendent and manager of the Octo G. M. Co., owning the Octo mine 6 miles west of Baker City, says arrangements have been made for increase of development work, which will be started this week, preparatory to resumption of milling operations. He also says he will start work on the Crown Point mine, near the Octo.

T. Kennerly of the Gold Coin mine, in the Greenhorn mountains, near Greenhorn, says he will resume work on that ground this spring. F. C. Ganter is superintendent.

The strike at the Eureka & Excelsior mine of the Mountain View M. Co. at Bourne has been settled and the men have returned to work.

The Tempest mine, Sumpter, will have a 100-ton smelter, says M. Blanchard of Portland, manager of the smelter company.

Douglas County.

C. C. Matthews, superintendent of the Oregon Securities Co. at Bohemia, says he is putting in additional machinery. The 30-stamp mill is expected to be ready for operation this month.

A body of ore has been opened in the Riverside group, near Bohemia, in the lower tunnel. The breast of the drift shows ore 7 feet wide. This tunnel is in 340 feet, and they have been drifting in the ore body for 200 feet. It is under the management of F. J. Hard.

Grant County.

P. A. Brady, superintendent of the Belcher and Red Lion mines near Granite, says arrangements are being made to put in milling machinery at both these mines, and operations will be started as soon as weather permits.

At the Badger mine, 1½ mile from Galena, near Susanville, owned by the Badger M. Co., work is progressing. The ore carries gold and silver. It has depth of 750 feet. Ore is sacked as it comes from the mine and is hauled by teams 40 miles to the Sumpter Valley railroad and shipped from there to the smelter. The company has a mill with which the low-grade ore is treated and the concentrates are shipped.——Spaulding, Stevenson & Simpson have put in a Huntington mill of thirty tons capacity to work a dump of tailings. There are several thousand tons of this, which is said to assay $8.

Jackson County.

The Golden Standard mine of Gold Hill district, owned by Kubli Bros. of Jacksonville, and which has been closed down, is being overhauled and made ready to resume operations.

Josephine County.

The Ada quartz mine of Foots Creek district, near Grants Pass, has been bonded by Manager Woodrow of the New York General Electric Co., and will put men to work next week, says the Telegram. He will continue development of the Ada and shape it for a stamp mill and plant. The mine is opened by tunnel and shaft to depth of 200 feet. A tunnel has been started on a deeper level and has been driven 80 feet. This tunnel will be completed. The ledge is 3 feet in width.

The Bagley Improvement Co. is doing work on Wards creek, east of Grants Pass, building reservoirs and constructing ditches, and will provide water in quantity for both placer mining and irrigation. The company's holdings cover an area of 1000 acres along Wards creek of both farm lands and placer ground. The gravel is said to lay from 8 to 10 feet in depth, and carries average values of 20 cents a yard.

The Van Dorn & Hedrick hydraulic placer mine, on Rogue river, below Grants Pass, is being overhauled. Larger ditches are being built and heavier piping laid.

The Golden Eagle mine at Provolt is in full operation and they are running a tunnel 150 feet to tap the ledge in the shaft, 60 feet in depth. The ledge in the shaft is 3 feet in width. The company which has this mine honded is superintended by J. Whitehead of Gold Hill.——The Sharp Bros. placer mine in Powells creek is worked steadily by pipe and rock hoists. ——A bond is being negotiated for on the Little Pocket quartz mine across the river, 1 mile from Provolt, owned by E. Hannum and A. Cook. It is idle at present.——On Missouri Flat the Gilkins M. Co. is placer mining on the Carris farm.

Lane County.

The 40-stamp mill for the Lucky Boy mine at Blue River is nearing completion, says L. Zimmerman, president of the company.

SOUTH DAKOTA.

Lawrence County.

The Columbus Con. M. Co. has closed its cyanide plant in Blacktail gulch, near Deadwood, and is shipping ore to the Hidden Fortune plant. The latter mill will he supplied with ore from both the Columbus Con. and the Hidden Fortune. F. E. Steele is in charge of the plant. The change was necessitated by condition of the wagon roads between Columbus Con. mine and mill, and also because the Columbus Con. cyanide plant was too small, says the Review.

The Dakota cyanide plant in Deadwood is dropping twenty-five stamps steadily. For several weeks the company has been bothered by heavy snow and consequent railroad blockades, which have interfered with ore supply from the mines. The mill requires three carloads a day.

Work has started by the Horseshoe M. Co., near Terry, on a flume to bring water from a spring on the southeast slope of Terry peak to its cyanide plant. When completed it is expected the spring for a time at least will supply all the water required to run the mill and do away with the expense of pumping from the Mogul shaft. Regular shipments of ore are being made by the Horseshoe M. Co. from the Mark Twain and Ben Hur mines to outside smelters for reduction.

Pennington County.

At Keystone M. Crocker is putting in a sinking pump in the J. R. mine shaft and work in the shaft will be resumed. —— F. Hebert has a carload of ore on the dump of the Clara Belle mine, which he will ship to Denver, Colo., for treatment. —— The Sunbeam company has stopped work in the mine temporarily and is only keeping the water out of the shaft. Prospecting work in the mine will be resumed with a diamond drill.——A. D. Arundel is doing development work on the 150-foot level of the Lena shaft. He is running a crosscut from the shaft south. At 40 feet a body of ore was broken into.

The Aberdeen G. M. Co. has been working steadily during the past winter on its mines near Hill City. An inclined shaft has been put down 110 feet with a whim. This company has four of the claims off the J. R. group. The principal work by the Aberdeen company is being done on the Surprise lode, from which the former owners of the J. R. took out ore. P. Daly is manager.

UTAH.

Beaver County.

Water supply for the Horn Silver concentrator at Frisco having been obtained, the plant is again in operation with thirty men on the payroll. The water supply as yet limits the crushers and tables to a feed of 140 tons daily. Manager Farnsworth says he has not resorted to the development of water by drill for the reason that the mine at depth of 1600 feet is practically dry. He has 100 men underground and continues extraction of copper ore.

The Majestic C. M. & S. Co., with mines near Milford, is in the hands of two receivers. R. R. Tanner has charge of the company's affairs in Utah and H. Altman in Colorado.

It is reported the stockholders of the Majestic C. Co. have voted to consolidate their holdings near Milford with those of the Monarch M. Co.

Grand County.

Ore is being hauled from the uranium mines near Richardson to the railroad, whence it is shipped to Niagara, N. Y., says the Times of Moab.

Juab County.

Shipments for month of March are largest in history of Tintic district, says the Tintic Miner. It required 617 railroad cars of forty tons capacity, the total exceeding 25,000 tons, or an approximate net value of $250,000. This tonnage was divided as follows:

	Cars of Ore.
Ajax	20
Bullion-Beck	27
Carisa	12
Centennial-Eureka	205
Dragon Iron Mine	36
Gemini	105
Grand Central	73
Lower Mammoth	32
Mammoth	44
Tetro	16
Uncle Sam	14
Yankee	11
Six others, a total of	16
Total	601

CONCENTRATES.	Cars.
May Day	2
Uncle Sam Con	4
Total	6

Superintendent Earls says he has reached the 700-foot level, with the winze in the south part of Bullion-Beck ground adjoining the Centennial-Eureka at Eureka, and will run a drift into the ore shoot, which was opened in the Moultoon tunnel. The 700-foot level in the Beck corresponds with the 1100-foot level of the Centennial. Lessees in the old workings shipped twenty-seven cars during the month.

The Mammoth mill, near Eureka, is being put into condition for work, says the Tintic Miner. Manager McIntyre will not longer await a favorable contract with the smelters for his low-grade product. Operations will be under way next week.

Work will be resumed on the King William mine at Tintic, near Eureka, this month, says C. H. Blanchard, the owner.——Operations have been resumed at the Eutonia M. Co.'s ground in West Tintic, near Eureka.

Piute County.

The Richfield M. & M. Co. has been incorporated at Richfield to operate in the Gold Mountain mining district, near Marysvale. The officers are H. W. Ramlose, J. Wilson and W. Ogden.

Salt Lake County.

Manager D. MacVichie, of the Bingham Con. C. Co., operating at Bingham, is considering adding lead furnaces to its smelter.

J. W. Langley has an option on the Gypsy Blair mine in the Big Cottonwood district, near Alta, for $50,000. The Gypsy Blair adjoins the Kennebec M. Co. ground, in which Geo. H. Robinson is interested. Its side lines are within 4000 feet of the Columbus Con.

On the Castro group of mines at Bingham development will begin under the Van Patten option next week, says the Tribune, the intention being to extend the tunnel begun by the owner, N. Castro, to the main ledge. From the main fissure mined by Castro copper ore has been produced. The owner has retained the placer ground.

Sevier County.

O. Larson, superintendent of the Log Cabin group of mines, near Richfield, reports developments showing $5 gold ore in sufficient quantity to justify putting up a mill. Since the exploration of a cross fissure by which the main ledge was intersected at the 500-foot station was begun, said the superintendent, it has swung around until it is running parallel with the latter. He says the value can be extracted by cyanidation. The general offices of the company, including the Gold Dev. M. Co., have been removed to Richfield, with Assistant Manager M. F. Murray in charge.

Summit County.

The new tailing plant of the Daly-West mine at Park City is nearing completion.

Tooele County.

On account of the heavy flow of water in the Honerine drain tunnel at Stockton work has been suspended in the adit. In the meantime the water in the workings of the various mines is rapidly being lowered. Until the volume of water recedes so that men can work readily, nothing will be done toward driving the tunnel ahead to the objective point.

WASHINGTON.

Ferry County.

D. F. Anderson of Rosalia, president of the Belcher M. Co., reports a railroad will be built this summer from foot of Curlew lake, near Republic, 6 miles up Lambert creek, to Belcher camp. As soon as it is built the Belcher will start shipping. It is expected work will start on the railroad by May 1 and be completed within forty days. The road is to connect with either the Hot Air line or the Great Northern. At the Belcher they are preparing to put in a tramway and electric drills this summer. They have 2500 feet of tunnels on the property and are in shape, says President Anderson, to start shipping 500 tons of ore a day as soon as the road is opened. The Portland mine has machinery on it and will also be ready to ship.

Skagit County.

The Canadian-American M. Co. of Belleville, N. O. Hughey president, proposes to put in additional machinery as soon as weather permits. The mine will be placed on a shipping basis of fifty tons per day.

Snohomish County.

(Special Correspondence). — Geo. S. Binckley of San Francisco, Cal., chief engineer of the Puyallup river power development of the Columbia Improvement Co., expects to have this plant completed by June 15. The exciters have been in use for some time, and the first main unit of the four, of 6000 H. P., was started April 2.

Electron, April 4.

Stevens County.

The Copper King mine, owned by the Chewelah Copper King M. Co., 6 miles northeast of Chewelah, is developed by 3500 feet of tunnel, shaft and drifts. The main tunnel is 1300 feet long and has opened three shoots of ore 4 feet wide, 13 feet and 25 feet. The ore is of copper with varying gold values, and carries a percentage of iron. Three cars of ore on the dump will be shipped as soon as the roads are in condition to haul to the railroad. Men are working this group under Superintendent D. F. Strobeck, who says he will take out and ship a car of ore per day.——The Jay Gould mine, owned by the Hertzell-Jay Gould M. Co., T. T. Hertzell president and manager, is also in operation. It is 3 miles east of Chewelah, with a good wagon road. The Jay Gould is a silver-lead claim, carrying values in copper and gold. The ledge is 25 feet wide, between walls of granite and serpentine. This is developed by 200 feet of shafts, levels and crosscuts. The main shaft is 180 feet deep, and follows the ledge. The mine is equipped with a 50 H. P. boiler, 30 H. P. hoist, steam pump and steam drill. It also has two reserve engines of 10 and 25 H. P.——The Nellie S. M. & M. Co., 1¾ mile east of Chewelah, is doing development work, says H. H. Baker, president.——The Eagle mine, the first producer of this camp, is idle.—— The Alice M. Co. has acquired, through a bond, the Echo and Juno claims, 1 mile east of Chewelah. These claims are near the Nellie S.

The six furnaces of the smelter at Northport were blown out last week, says Manager E. I. Wilson and men are at work putting up a sampler and crusher, the machinery for which is at hand. It is also stated that the smelter with its present facilities and the present condition of its furnaces is unable to get certain custom ores containing fluxing properties necessary to smelt Le Roi ores to best advantage. These ores have been promised if necessary repairs are made. Smelting will resume next week.

Whatcom County.

T. P. Saunders, president of the Great Excelsior mine in Mount Baker district, east of Whatcom, says the capacity of Mount Baker mill will be doubled and other mines will put in machinery. Besides the smaller properties that will put in plants, the Great Excelsior, which has twenty stamps dropping, will add eighty more. The B. B. & I. R. Railway is building to the camp.

WYOMING.

Carbon County.

The Ferris-Heggarty mine, near Dillon, has resumed its output of ore and 100 more men were put on last week, says the Dillon Doublejack. The number will be further increased. Considerable ore that has been broken down during the winter is in the bins and will supply the tram for a time.

Laramie County.

Heavier machinery is being put in at the iron mines of the Colorado Fuel &

Iron Co. of Pueblo, Colo., at Sunrise. The weight of the compressor is 102,200 pounds. A large number of drills will be set to work and the number of men increased. The demand for this ore is said to be the call of the Moffat road and the Colorado & Southern for rails. The flywheel of the compressor weighs 20,000 pounds and is 16 feet in diameter. It will furnish power for thirty drills. The present complement of drills in the mine is eight. For another of the company's mines it is expected a 60-drill compressor will be put in.

FOREIGN.

AFRICA.

Rhodesia.

The total gold output of companies making returns to the Rhodesian Chamber of Mines at Bulawayo for month of February is reported at 18,673 ounces (Matabeleland, 15,481 ounces; Mashonaland, 3192 ounces)—a decrease of 686 ounces as compared with the previous month and an increase of 1583 ounces as compared with the corresponding period of 1903. The silver output for January was 3521 ounces and for February, 3461 ounces.

AUSTRALIA.

Western Australia.

At Bayley's mines at Coolgardie the diamond drilling contract has been finished, proving the continuation of the new reef at 600-foot level and at 250-foot level Price shaft. They have started sinking winzes, preparatory to mining and milling. In winze from 800-foot level of Price shaft, reef averages 3 feet in width, assaying 60 pennyweights of gold. The reef has been opened up in the 1000, 900 and 800-foot levels of Price shaft.

The Great Fingall Con. at Kalgoorlie reports the first twenty of the new stamps started dropping March 15.

The Lake View Consols mine at Kalgoorlie reports February returns at 8403 tons of ore treated, yielding 4206 ounces fine gold. Costs—ore extraction, 13s 3d per ton; ore reduction, 13s 5d per ton; total working expenses, (including general expenses) £1 6s 8d per ton, or total of £11,204. Expenditure on machinery and plant, £407; expenditure on mine development, £2220.

At Kalgoorlie Bowick, Moroing & Co. have taken over the White Feather Main Reef mine, and J. Pollard is manager. Since 1895, when the Reef was first prospected, its main ore body has been followed to a vertical depth of 850 feet. The official records show that up to Feb. 1, 1904, the mine has yielded 79,550 ounces of gold from 90,489 tons crushed.

The Kalgurli mine, at Kalgoorlie, is preparing to put in additional milling power. It is proposed to increase the treatment capacity of the plant to permit of 7500 tons of ore being handled monthly.

BRITISH COLUMBIA.

Boundary District.

With the Granby and the Mother Lode mines shipping their usual quota to the smelters, Boundary miners have this year to April 1 sent out over 200,000 tons of ore with value estimated at $1,000,000.

Cassiar District.

In Atlin division mining work is increasing. C. B. Gaddis, manager of the Spruce Creek Power Co., which owns 1360 acres of claims on the Spruce near Atlin, says his company will put in a $150,000 hydraulic plant. The Pine Creek Power Co., owning 1000 acres of gold-bearing ground on Pine, will increase development work this year. F. T. Blunck of Iowa and L. H. Griffith of Seattle, Wash., are part owners in the Pine Creek Co.——The British-American Dredging Co. will operate two dredgers in Atlin the coming summer. T. Schwitzer is manager of the company, which is owned by Philadelphia, Pa., men.

The Switzer-Robinson M. Co. has been organized to operate the Blue Canyon and Deniston group of leases on Upper Spruce and Upper McKee creeks, near Atlin. The lower end of Blue canyon was prospected last year by a traction driller, with Superintendent Richards in charge. This year the driller will continue prospecting above the canyon. There are twenty-two leases, and the ground is said to be suitable for dredging.

East Kootenay District.

The Imperial Coal & Coke Co. has increased its holdings of land near Michel.

Nelson District.

M. S. Logan of Nelson, managing director of the Juno, on Morning mountain, near Nelson, says it is proposed to build reduction works, consisting of a stamp mill and other equipment. The Juno is above the Venus-Athabasca group. A drift was run on the continuation of the Venus lead, tapping the main Juno lead at depth of 300 feet. By sinking and raising a connection was made with the surface. Crosscuts are said to show 8 feet of milling ore. To continue development a lease was secured on the No. 2 tunnel of the Venus mine and a raise is being run to connect with the upper workings on the Juno ore body. Arrangements have been made for a supply of air from the Athabasca compressor, which is also furnishing air for the Venus mine. Machine drills will then be put in the Juno.

Rossland District.

Arrangements are closed for building a railroad siding a mile long around the base of Columbia mountain, near Rossland, when snow goes off. It will afford transportation facilities for the Iron Colt, Mascot and Kootenay mines. They have low-grade iron ores. All three have teamed their produce over a wagon road, and the reduction of $1 per ton in the cost of laying down the ores at smelters over a railroad line throughout, it is expected, will be inducement for operation of all three.——An electrically operated pump is being put in at the Spitzee mine, where the present pumping apparatus has been operated from the compressor plant. The mine will operate another machine drill and increase its working number to twenty-five men. The main drift on the 200-foot level shows the ore and the crosscuts open a shoot averaging 8 feet in width and carrying $12 in values. This spring the main shaft will be continued to the 350-foot point.

Slocan District.

The Black Warrior mine, near Sandon, will be worked this season.——The Arlington M. Co., at Slocan, will build a mill this summer.——The owners of the Horseshoe mine, at Trout Lake, are busy sacking high-grade ore for shipment.——The Queen-Dominion M. Co. has put men to work on the Queen Bess mine, near Sandon.

Vancouver Island.

The Crofton smelter is getting twenty tons of ore daily from the Richard III mine, on Mount Sicker. Preparations are being made at the Yreka C. Co. mine, on Quatsino Sound, for increased shipments to the smelter. Breen & Bollingor, who own the smelter, have contracted for 100,000 tons of ore, and a steamer will be put on the run between Crofton and Quatsino to transport the ore.

West Kootenay District.

The clean-up at the Oyster-Criterion mill at Camborne for month of March is reported at $5200 by B. Crilly, assistant manager of the Great Northern M., Ltd. The mill crushed 1000 tons, giving value of $5.20 per ton in gold saved on the plates, besides the concentrates. Bullion was shipped to the United States Assay office at Helena, Mont. For the first month's run the gold bullion assayed $14.73 an ounce, and has since shown increase. The south drift on the Oyster claim is running in a payshoot.

The Silver Cup and Nettie L. mines, near Trout Lake, will resume operations by May 1.

The tunnel on the Swede group at Poplar is in 100 feet and will be extended another 150 feet before it cuts the vein.——The Motropolitan G. & S. M. Co. intends putting in an aerial tram at the Triune mine, near Ferguson. —— The Marie-Marilla M. Co. intends resuming work on the Pedro and Minnie F. claims in the Lardeau as soon as supplies can be taken in.

Development work will be started on the Old Gold, Mountain Lion and Primrose mines near Lardeau as soon as the trails are passable.——The tunnel on the Home Run mine is in 60 feet and nearing the ledge. Several stringers have been cut.

A. F. Rosenberger, manager of the Gold Finch M. Co., with beadquarters at Nelson, has work under way. The property was formerly owned by the Northwestern Dev. Co. and had considerable development work. The ore carries free gold. A mill was also built.

The Metropolitan G. & S. M. Co., R. H. Battey of Minneapolis, Minn., president and manager, will reopen and increase work on its mines near Ferguson this month. Manager Battey will superintend operations and will remain during the season. A double-rope aerial tram from the Tribune mine to the base of the mountain near Ten Mile will be built.

CANADA.

Nova Scotia.

A company of Canadian and American men has been formed to operate the submarine coal area extending beneath the ocean on the eastern side of Cape Breton, writes W. R. Holloway, U. S. Consul-General at Halifax. These areas, it is claimed, comprise 27 square miles and the seams have a total thickness of 31 feet. In 1860 a colliery was established at South Head with small capital, and 7000 tons were mined; while the workings extended below the sea level, the mine was dry and the coal of good quality.

ENGLAND.

Cornwall.

The copper mining industry is decreasing in importance in Great Britain, writes H. Fox, U. S. consul at Falmouth. Forty years ago the production of copper ore and copper precipitate amounted to 210,000 tons annually, whereas in 1902 the production was 6112 tons. Cornwall is the main source in the United Kingdom of the supply of this ore. Tin mining, which is also mainly confined to Cornwall, has also decreased. Cornish tin ore occurs both in the granite and in the adjoining slate. Nearly one-fourth of the output in 1902 was raised from the Dolcoath mine, which yielded 1828 tons. The Cornish granite trade is being affected by competition of Norwegian granite to such an extent that some English firms have acquired and are working quarries in Norway.

MEXICO.

A government report shows that there are 9000 mining properties paying taxes in Mexico at present, says the Mexican Investor, and the following official statement is given on mineral production of Mexico for the fiscal year 1902–3:

Silver	$ 82,300,000
Gold	32,500,000
Copper and copper ores	19,600,000
Lead and lead ores	5,670,000
Antimony and antimony ores	1,139,000
Asphalt and coal	35,000
Marbles	150,000
Other minerals	200,000
Total production, 1902–3	$141,594,000
The mineral production in the fiscal year 1901–2 was	$113,057,000

These figures are in Mexican silver and do not include about $3,000,000 of gold and silver consumed in the Republic.

Chihuahua.

T. H. McConnoll is building a reduction plant at Guadalupe y Calvo for the Rosario mine. The equipment includes tanks for cyanide process.

The Pan American M. & S. Co. is operating the Quebradillas mine, near Parral, with J. W. Pender as manager. The company is also operating the Grenadena mine, near Santa Barbara, and the Iguana mine, near Parral. At the Iguana underground work is temporarily suspended, pending putting in of beavier pumps.

The Adela mill at Santa Barbara has been sold to B. Peterson and J. F. Johnston, who are oporating a group near there carrying gold ores.

The Gorham Mfg. Co. of New York is again operating the Cerro Colorado mine at Parral and is shipping 1500 tons of ore monthly, says the Enterprise. The reduction plant is idle. H. A. Ladd is superintendent.

B. Davis of Chihuahua, manager of the San Pedro mines and the Corralitos L. & C. Co. in northern Chihuahua, says the principal work at those mines under way is sinking a new shaft, and that a pumping plant will be put in next month.

C. Barbier, who, with F. Ramirez, has a lease on La Reina mine at Cusihuiriachic, has started up the Burns mill at that place. The mill has capacity of forty tons per day.——It is reported the Helena M. Co. will resume operations on its mines at Cusihuiriacbic. The company is owned hy same men as are in the Calera mine, near Minaca, and the Chihuahua M. Co. and El Potosi M. Co. at Santa Eulalia. The Helena Co.'s mines have been idle for several years and the workings are more or less filled with water.

The Buena Ventura M. Co., with bead office in Washington, D. C., and branch office in Denver, Colo., has been incorporated and has taken over the lease and hond on the Buena Ventura mine and the fractions San Jose and Guadalupe, aggregating 8½ pertenencias, 3 miles from Parral and 2000 feet from Alvarado's Palmilla mine. The principal values are silver and gold. The officers are L. M. Goddard of Denver, Colo., J. W. Pender of Parral (manager), J. Liveze, R. S. Donaldson and S. C. Warner. The price is stated at $125,000 gold. They are starting development work by sinking a two-compartment shaft and will put in a hoisting plant. The shaft will be sunk 400 feet. Tho ores are said to run thirty ounces in silver and $4 gold.

The Santo Domingo placer mines, 85 miles east from Chihuahua, on the Conchos river, have been sold to the Mexican Gold Fields Co. These placers cover 3000 acres. The gold is distributed through 35 feet in depth of alluvial deposits down to an auriferous "caliche" (false bedrock). This has heen tested by 150 boles down to this hedrock. The placers are on both sides of the Conchos river where there are fully 10,000 inches of water flowing the year around, says the Enterprise. The Mexican G. F. Co. will put in machinery for extracting the values. It is intended to use hydraulic, steam shovels, and dredging methods. The mines are 42 miles from Las Trancas, the present eastern terminus of the Kansas City, Mexico & Orient Railroad, and grading, which is going on, is approaching the property. E. A. Horner of Leadville, Colo., is president and manager, with G. H. Hoverland and P. P. Harris of Chicago, Ill., treasurer and secretary, respectively.

At Sierra Almoloya, between Jimenoz and Parral, the Almoloya M. Co., N. O. Bagge of Los Angeles, Cal., principal owner, and D. W. Sbanks, manager, will put up a central electric power plant for the operation of its mines with capacity of 150 H. P. It will be built at Dorado station, on Parral branch of Mexican Central and 5 miles from tho mines.

Sampling works are being built for P. Alvarado, owner of the Palmilla mine at Parral. Thoy are being put up adjoining Alvarado's electric power plant beside the Parral & Durango Railroad.

The Compania Minera de Naica is preparing to put up hoisting machinery, ore bins and chutes to handle a larger output from its mines at Naica, 16 miles from Conchos station, on the Mexican Central, says Superintendent J. Garrett. The company has its railroad to Conchos station completed.

It is reported the Companie Mexicaine Sud-Orientale, a Belgian corporation, of which L. Pellegrini at Chihuahua is consulting engineer, has an option on La Central, Bustillos and Juarez mines of M. Ramirez in Santa Eulalia camp. The three mines aggregate 196 pertenencias.

P. H. Hefron and J. W. Piper of Washington, D. C., are putting up a 2-stamp quartz mill at the r 2nd of April mine, west of the Dolores mine, west of Chihuahua. Work on the mines is progressing.

Sinaloa.

G. L. Sheldon of Cboix, manager of Las Tajos Dev. Co., a Pittsburg, Pa., company, operating mines at Cboix and at Morelos, Chihuahua, reports work progressing at both properties. He says a Milwaukee, Wis., company is preparing to exploit placer deposits, one of 20 miles in extent along the Cboix river and another of 50 miles along El Fuerte river. This company has put in six gasoline engines and other machinery for pumping water up to the mesa. Las Tajos Dev. Co. has been developing Las Tajos copper mines at Choix and since last November has done over 800 feet of work. On the Morelos mine, which is silver-lead, 600 feet of work bave been done in same time. Tbo putting in operation of the Orient road from Topolobampo to El Fuerte has been of assistance to mining in and about El Fuerte and Choix.

Sonora.

B. F. Graham of Bisbee, Ariz., president of the Tigre M. Co., says a reduction plant (possibly lixiviation process) will be put in at tho company's mines. He says the erection of a reduction plant will make considerable saving in cost of operation, owing to the fact tbat the mine is several miles from the railroad and hauling in wagons is expensive.

J. Douglas of the Greene Con. C. Co. at Cananea, says they have reduced the cost of concentrating from $1.50 to 82 cents per ton, and expect to get it down to 70 cents per ton. The cost of treatment and concentrating (four into one) is $4.40 per ton. Results for last month showed that 3.1% copper ore gave a profit even under present conditions with the concentrator not working. At the present price of copper, 2% ore has a value of $5 per ton. That the Greene is not a shallow mine is shown by the fact that from the croppings the Veta Grande has been opened to 1160 feet and on the Capote 1222 feet, says Douglas. The sbaft is started from the bed of the gulch and the workings are down 800 feet.

The Sonora M. & M. Co. has closed a deal with the Mexican Exploration Co. taking over forty-two portenencias of mining property together with 6000 acres of timber land, with water supply, near Tubutama, in Altar district. It is 40 miles from tide water and is on the line of the proposed railroad to Point Lobos.

Near the Copete mine, near Copete, the Sultana group, owned by J. L. Giroux of Los Angeles, Cal., is being worked. In the principal workings the shaft has reached a depth of 1050 feet, in ore all the way, and is said to have developed in the lower levels an ore body 30 feet between walls, carrying copper, silver, gold and lead values. In the Columbia, an adjacent mine in the Sultana group, an incline is down 337 feet in ore carrying 15% copper.——Adjoining the Sultana, on south side of the Cerro del Oro, is the Colorado group, owned by C. S. Mills et al. There are 3000 feet of development work and gold ore has been blocked out ready for stoping and reduction. Connected with the property is a small mill at Carbonera, which Manager Mills proposes starting this month. As soon as an adequate water supply can be secured the mill will be moved up to the mine, 5 miles away, and be enlarged.

Personal.

R. M. BRERETON is examining mines in Tonopah, Nev.

JNO. Y. MCKANE of Tonopah Nev., is in San Francisco, Cal.

W. C. CALDER of Sumpter, Or., is in the East on mining business.

DR. W. J. MURPHY has returned to Manvel, Cal., from Los Angeles, Cal.

J. H. MCNICHOLAS, of Portland, Or., is in Cleveland, O., on mining business.

O. P. POSEY of Los Angeles, Cal., is in San Francisco, Cal., on mining business.

J. E. KING of Mokelumne Hill, Cal., is in San Francisco, Cal., on mining business.

C. J. BANDMANN, of San Francisco, Cal., is examining mines at Tonopah, Nev.

CHAS. P. RICHARDSON has returned to Newsome, Idaho county, Idaho, from Chicago.

J. C. STRONG of Butte, Mont., interested in Montana mines, is in San Francisco, Cal.

B. F. HARTLEY is superintendent of the Three Stars mine at Auburn, Placer county, Cal.

E. A. THIES succeeds his father, Adolf Thies, as general manager of the Haile, S. C., G. M. Co.

J. C. SULLIVAN is superintendent of the Raymond-Illinois groups near Eureka, Juab county, Utah.

S. G. KNOTT has resigned as manager of the Nancy Tunnel at Wall Street, Boulder county, Colo.

N. A. WALLINGER is assayer at the North Star mine near Fort Steele, B. C., vice N. T. Kingshury.

NORMAN A. ROOT is now connected with the firm of Harron, Rickard & McCone, San Francisco, Cal.

N. HARPER has retired as manager of the White Feather Main Reef mine at Kalgoorlie, Western Australia.

H. W. LOTSHAN of Puehlo, Colo., has returned there from Portland, Or., where he has heen on mining business.

R. J. COLEMAN of Denver, Colo., part owner of the Lluvia de Oro mine in Chihuahua, Mexico, is at the mine.

T. S. WOOD has returned to Leadville, Colo., from Santa Barbara, Cal., where he has been during the winter.

IVAN DE LASHMUTT goes from Butte, Mont., as professor of metallurgy at the University of Arizona, Tucson, Ariz.

F. H. FLOOD of San Francisco has gone to Curlew, Wash., to superintend the mill and cyanide plant of the Bodie M. Co.

E. L. HOLLINGSHEAD, manager of the Weyant M. Co., of Pollock, Idaho, is in San Francisco, Cal., on mining business.

W. J. ADAMS, mining engineer, has returned to San Francisco, Cal., from an examination of mines in Mariposa county, Cal.

PRESIDENT J. E. BAMBERGER of tbe Daly West M. Co., of Park City, Utah, is in the East, after a trip to Los Angeles, Cal.

FERD. RUTTMAN has resigned the superintendency of the Vacas-San Marcos M. & M. Co., and returned to New York City.

W. BALL has resigned as superintendent of the Lower Mammoth M. Co. at Tintic, near Eureka, Utah, and is in Lehi, Utah.

S. L. BUTLER has returned to Salt Lake City, Utah, from Mexico, where he has heen looking after his mining interests.

J. H. HAMMOND, general manager of the Guggenheim Exploration Co., is inspecting the mines of his company in Mexico.

A. F. ROSENBERGER is manager of tbe Gold Finch M. Co., operating at Camborne, B. C., with headquarters at Nelson, B. C.

R. M. CAMERON, owning mining interests in Plumas county, Cal., returned to Quincy, Cal., last week from a trip to Nampa, Idaho.

S. B. EDWARDS, State Mining Inspector, with headquarters in Gunnison, Colo., is examining mining property at Leadville, Colo.

T. S. VAN FLEET, of the Gold Bug mine, near Sumpter, Or., has gone to New York, N. Y., and Boston, Mass., on mining business.

L. V. SWIGCETT, of Portland, Or., of the Golconda Extension mine, in eastern Oregon, is on a mining business trip to Philadelphia, Pa.

W. H. MCCORD, mining engineer for El Cuho M. & M. Co. at El Cubo, Guanajuato, Mexico, is in San Francisco, Cal., on mining business.

J. FITZGERALD has resigned as manager of the P. and O. mine, at Querida, Custer county, Colo., and has gone to Colorado Springs, Colo.

O. D. COLVIN, Seattle manager of the American Steel & Wire Co., will become the manager of the Snoqualmie Falls & White River Power Co.

D. H. PEERY and C. K. MCCORNICK of Salt Lake City, Utah, have returned there from a trip of several weeks to California on mining business.

E. M. RAY, till recently at Parral, Chihuahua, Mexico, is manager of the Pinos Altos mines of W. P. Dunham & Co. at Pinos Altos, Chihuahua, Mexico.

J. MCLELLAN has resigned as assayer for the Calumet & British Columbia G. M., Ltd., at the Eva mine, at Camhorne, B. C., and has gone to Montana.

J. P. WEYANT, of Toledo, Ohio, secretary of the Weyant M. Co., operating in Seven Devils district, Idaho, is in San Francisco, Cal., on mining business.

C. E. EDDY of Salt Lake City, Utah, interested in the Lost Packer mines at Loon Creek, Idaho, is examining mines at Goldfield and other Nevada camps.

PRESIDENT J. A. BISHOP of the Walcott G. M. Co. has succeeded J. Fitzgerald as manager of the P. and O. mine, at Querida, Custer Co., Colo., near the Bassick mine.

S. H. PITKIN, first vice-president of the Wellman-Seaver-Morgan Co. of Cleveland and Akron, Ohio, returned this week from a business visit to San Francisco, Cal.

WM. L. SAUNDERS succeeds the late Wm. R. Grace as president of the Ingersoll-Sergeant Drill Co. of New York. Mr. Saunders was vice-president of the company since 1897.

ASSISTANT MANAGER M. F. MURRAY of the Log Cabin mines, near Richfield, Utah, is in charge of the general offices of tbe company, which have been moved to Richfield, Utah.

W. MITCHELL, superintendent of the Nancy Tunnel at Wall Street, Boulder county, Colo., has been appointed manager of the same company, vice S. G. Knott, resigned.

S. I. HALLETT, of Aspen, Colo., has resigned as consulting engineer on the Smuggler mine, to take effect May 1st, when he expects to make a prospecting trip through Idaho.

F. E. STEELE, recently mill superintendent of the Columbus Con. M. Co., near Deadwood, S. D., has charge of the Hidden Fortune plant in same section, vice W. A. Kelly, resigned.

T. GOODWIN, manager of the New Monarch group of mines at Leadville, Colo., and the Ohio & Colorado smelter at Salida, Colo., returned to Leadville last week from a business trip East.

EDW. DOERR, general manager of the Mexico Guggenheim Exploration Co., has resigned. It is reported in Denver that hereafter the Mexican general offices will be abolished and the business transacted from the Denver office, with A. Chester Beatty in charge.

F. D. BROWN has resigned as manager of the Basin Gulch placer property and the American Jim Co., and will he succeeded by J. Sorenson as manager of tbe Basin Gulch workings, and C. Wipf, who will have charge of the American Jim, near Phillipsburg, Mont.

J. POLLARD, formerly at the South Eureka mine, Sutter Creek, Cal., and lately mine superintendent of the Lake View Consols mine, at Kalgoorlie, Western Australia, is superintendent of tbe White Feather Main Reef mine at Kalgoorlie.

Commercial Paragraphs.

THE National Metal Co. bas absorhed the firm of P. G. Roeder & Co., Mexico City, Mexico.

B. C. RIBLET has a contract for an aerial rope tramway at the Alice mine, Creston, B. C.

THE Fulton Iron Works of San Francisco, Cal., is building a 200-ton smelter for the Empire Smelting Co.

THE New York office of the Colorado Iron Works is now in the Engineering Building, 114-16-18 Liberty street. S. W. Traylor is the New York manager.

BEAUDRY & CO. of Bostou, Mass., builders of the Beaudry champion power hammer, announce the removal of their offices to the new Oliver Building, 141 Milk street, corner of Oliver.

F. L. SMIDTH & CO., engineers and manufacturers of modern grinding machinery, with offices at 80 William St., New York City, will move to larger and more convenient quarters in the Taylor Building, 39-41 Cortlandt St., New York, on May 1.

THE Canadian Westinghouse Co., Ltd., of Hamilton, Canada, have engaged C. C. Starr, formerly with the firm of John Starr, Son & Co., as their representative in the maritime provinces, with headquarters at 134 Granville street, Halifax, Nova Scotia.

Trade Treatises.

The Latham Machinery Co., 195 South Canal street, Chicago, devotes its most recent catalogue to illustrated description of its Monitor duplex punching machines.

"Chrome Steel Stamp Mill Parts" is a brochure from the Chrome Steel Works, Chrome, N. J., G. W. Myers, Hayward Bldg., San Francisco, Cal., Pacific coast representative. Hydraulic forged shoes and dies, tappets, bossheads and Canda cams are illustrated and some testimonials annexed.

Catalogue No. 4 from the Thew Automatic Shovel Co., Lorain, Ohio, gives a sectional view and detailed notice of the Thew single truck shovel, with halftones of its different types, as designed for railroad, mining and contract work. The Thew shovel for handling ores is also given considerahle illustrated prominence. Dipper dredgers and special conditions pertaining thereto form the concluding part of this booklet, which will be sent anywhere on request.

"Wire Rope Tramways," from the Hallidie-Painter Tramway Co., 46 Fremont street, San Francisco, Cal., is the latest trade issue of illustrated information concerning this form of telpherage, embracing automatic aerial wire rope tramways; the double-rope, single-rope, two-bucket, one-bucket and special systems; hoisting and conveying cableways and surface trams. The excavating system, which combines the aerial tramway system with excavating, grading and conveying material, is also exemplified.

Dividends.

Bunker Hill & Sullivan M. & C. Co., Idaho, $45,000; paid April 4.

Latest Market Reports.

SAN FRANCISCO, April 8, 1904.

METALS.

SILVER.—Per oz., Troy: London, 25⅛d (standard ounce, 925 fine); New York, har silver, 54⅝c, refined (1000 fine); San Francisco, 54⅝c; Mexican dollars, 43½ San Francisco, 43½c New York.

COPPER. — New York: Standard, $13.25; Lake, 1 to 3 casks, $13.50; Electrolytic, 1 to 3 casks, $13.12½; Casting, 1 to 3 casks, $13.12½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £58 12s 6d spot per ton.

The copper market the past week has shown increasing strength and prices have made a material advance. There appears to be a general opinion that copper is going still higher, but that it will go ahove 14 cents is not probable, unless a heavy l uying movement commences. Any attempt in this direction, bowever, is always met hy a firm market and higher prices, which promptly cbecks huying, unless the consumers are satisfied that the producers are not turning out the metal in excess of the demand, in which case all buyers seek to secure contracts at as low figures as possihle before the inevitable raise in price.

LEAD. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, har 5¾c; pig, $4.85. London: £12 6s 3d ℔ long ton.

SPELTER.—New York, $5.30; St. Louis, $5.00; London, £22 5s ℔ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $28.35 @ 28.65; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 31c; less, 32c; bar tin, ℔ lb., 32½@35c. London, £127 6s 6d spot.

PLATINUM. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75 @ 82c ℔ gram.

QUICKSILVER. — New York, $45.50@46.50, large lots; London, £8 5s 0d; San Francisco, local, $43@44 ℔ flask of 76½ lbs.; Denver, $46.00. Export, $43.00@43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

NICKEL.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $13.85 @14.35; gray forge, $12.60; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ℔ lb.

Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., hhl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bhls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb., 7c; less than 500 lbs., 7½c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ℔ lb.

BORAX.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ℔ lb., 60c.

SODIUM.—Metal, ℔ lb., $1.00.

BISMUTH.—Subnitrate, ℔ lb., $2.00.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—$2.00 ℔ lb.

CHROMIUM.—90% and over, ℔ lb., $1.00.

PHOSPHORUS.—American, ℔ lb., 75c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING MARCH 29, 1904.

755,837.—EDUCATIONAL DEVICE — E. W. Barker, Oakland, Cal.

756,096.—HAND TRUCK — E. J. Bryan, Riverside, Cal.

756,195.—HARROW—E. H. Cheever, Oceanside, Cal.

755,845.—TIME SWITCH—Cherry & Radke, S. F.

755,628.—AWL—J. L. Davidson, Los Angeles, Cal.

756,161.—ATOMIZER—J. P. Farmer, Portland, Or.

756,102.—FOLDING BED—H. Faschinn, S. F.

755,758.—GAGE—C. W. Foust, Los Angeles, Cal.

755,809.—STRING CUTTER — Hanaao & Rodennver, S. F.

755,659.—WATER HEATER—J. F. Hathaway, S. F.

755,660.—FIRE ESCAPE—W. G. Horton, S. F.

755,880.—OIL BURNER—A. Johasoa, S. F.

756,116.—OIL BURNER — W. S. Keagin, Tucson, Ariz.

755,899.—ELECTRIC RAILWAY — T. Mahoney, S. F.

755,691.—TELEPHONE—McKinsey & Nelson, Susanville, Cal.

755,923.—LATCH—T. O'Shaughaessy, San Jose, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

POWER TRANSMITTING APPARATUS.—No. 755,799. March 29, 1904. M. L. Schlueter, Oakland, Cal. This invention relates to an apparatus which is designed for the production and transmission of power; it consists of a plurality of trains of gearing arranged in pairs, each pair operating alternately upon a main power shaft, to which an approximately continuous motion is given by the plurality of devices acting thereon. Intermediate between the gears and the main shaft are pawl and ratchet mechanisms, which operate alternately as power is communicated in each pair.

ELECTRIC RAILWAY SYSTEM. — No. 755,899. March 29, 1904. T. Mahoney, San Francisco, Cal. This invention relates to improvement in means for operating electric railways of the type employing a sectional trolley rail having its sections normally out of circuit with the main and adapted to be energized momentarily and successively by the passing car. Its object is to simplify construction, reduce cost, afford perfect insulation, and particularly to overcome the difficulty heretofore experienced in many of the magnetically operated switch systems in cutting in the current when the car is traveling at a high rate of speed.

OIL BURNER.—No. 755,880. March 29, 1904. August Johnson, San Francisco, Cal. This invention relates to certain improvements in oil or hydrocarbon burners. It consists in a means for supplying air and regulating the supply and means for distributing the oil and air to the burner, and other parts of construction.

CULTIVATOR.—No. 755,932. March 29, 1904. M. Pruya, Florin, Cal. One-half assigned to R. M. Jones, Florin, Cal. This invention relates to improvements in devices for cultivating the earth, and is especially applicable to that class of cultivators known as the "A-cultivator," having sides diverging from the front, where they are united, and provided with cultivating teeth. The improvement consists in the employment of reversed or convergent bars hinged to the rear ends of the divergent ones and means by which the rear ends of said bars are drawn toward or separated from each other.

MACHINERY FOR SALE.

Send FOR OUR Machinery List.

Boilers, Engines, Crushers, Rolls, Stamps, Gasoline and Steam Hoists, Pumps, Etc.

KENYON & GRANT MACHINERY CO.,
CRIPPLE CREEK, COLO.

FOR SALE.

Several Lots of New and Second-Hand Standard Rotary Mine Cars at a low figure.

Also, New and Relaying Rails---12, 16, 20 and 25-pound. Immediate delivery.

THE ATLAS CAR & MFG. CO.
CLEVELAND, OHIO.

Dredger for Sale.

A clam-shell dredger used only six weeks and in first-class condition. Hatch steel bucket, capacity 2 cubic yards level full; boiler 48 in. x 16 ft., return tubular; main engines are 12x18; spud engines are 8x12, solid bed plates; two large friction hoisting drums; three friction drums for handling spuds; machine set up with frictions, clutches, traveling spud, two main spuds, hoisting and spud chains, capstan, feed pump and every part complete in every detail and ready to run; weight of all iron work and machinery 493¼ tons. Machine cost $19,500; will be sold at less than 25% of cost price.

Also: Two 3-ft. Pelton wheels, $50 each.

Two 6-ft. new Pelton wheels, double nozzles, cost $600 each, price $125 each.

Three Woodbury Concentrators, only used three weeks, price $90 each.

Address Box 29, Mining and Scientific Press, San Francisco, Cal.

1000 ft. 8 in. Riveted Flanged Pipe, made for heavy head of water. Has never been used and will sell 25% less than new pipe.
1—125 H. P. 220 volts Commercial Motor.
1—40 H. P. 220 volts Northern Motor.
1—1 H. P 220 volts 4 ampere Northern Motor.
2—1 H. P. Sturtevant Blowers, direct connected with 1 H. P. Northern Motor.
1 Ingersoll-Sergeant 20x36 single stage Compressor.
1—1¼ Boggs-Clark Centrifugal Pump mounted on sub-base for motor connections.
2000 ft. 12 in. Wrought Iron Pipe.
570 ft. 10 in. Sheet Iron Pipe with flanges.

S. S. MACHINERY COMPANY,
1529 Lawrence St., Denver, Colo.

Special Bargains!

The following items are offered for sale at extremely low prices. This list represents but a very small part of the Machinery and Equipment that we have for sale. We would advise you to write us before making any purchases in the Machinery line. Our stock is the LARGEST on earth. (These items are extracts from our Machinery News. Have you a late copy?)

AIR COMPRESSORS.

20x20¼x24 Ingersoll-Sergeant straight line steam driven air compressor, with unloading device and pressure tank.
12x12 Snyder-Hughes, duplex, belt driven.
8x6x8 Clayton, steam driven, duplex.
8x8 single, belt driven, Clayton.
7x7 single, belt driven, Clayton.
12x12x14 steam driven.
24x12x24 Ring.
20x20x24 Eastern.
10x10x10 Laidlaw, Dunn & Gordon.

HOISTING MACHINERY.

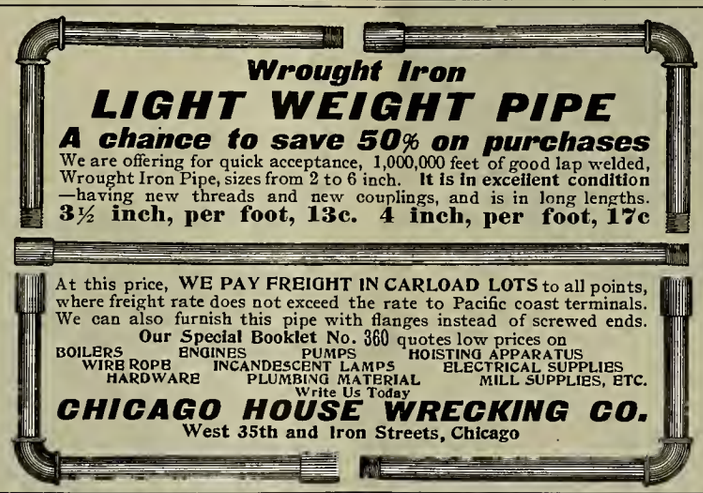
M. C. Bullock hoist, consisting of Webster, Camp & Lane drum, 5 ft. dia. x 9 ft. face, or we can make two drums, one 5 ft. face and the other 4 ft. face—direct connected to 18x24 Atlas slide valve engine, with double brake stands and all equipment.
10x14 double cylinder, single drum Marinette hoisting engine, with drum 5 ft. dia. x 4½ ft. face, complete with brake and driving stands.
12x16 double cylinder, single drum Marinette hoisting engine, with drum 5 ft. dia. x 4½ ft. face.
8x12x14 McEwen tandem compound engine and 35 k. w. 110 volt C. & C. generator direct connected.
30x16 Fraser & Chalmers Corliss engine in excellent condition, all complete, ready for immediate shipment.
22x48 Wheelock Corliss engine.
25x10x24 Gordon duplex steam pump.
Bullock "Champion" diamond prospecting core drill, with 800 ft. of rods and complete equipment. Will sell at a bargain.
3—60x16 horizontal tubular boilers, triple butt strap riveted.
2—No. 4 Cameron mine pumps.
2—No. 7 Cameron mine pumps.
3—50 H. P. Erie City "Economizer" boilers.
160 H. P. locomotive fire-box boiler.

WIRE ROPE.

We have in stock a quantity of fine second-hand wire rope, six strands 19 wires to the strand, which has not seen excessive service and which is in first-class condition for further use: 65,000 ft. 1¼ in. 12c ℔ ft.; 42,000 ft. 1⅛ in. 11c ℔ ft.; 13,060 ft. 1⅛ in. 14c ℔ ft.; 1½ in. 13c ℔ ft.; 2 in. 18c ℔ ft.; 2¼ in. 24c ℔ ft.

In addition to the above we have all sizes of cable ranging from ⅜ in. up. OUR CATALOGUE NO. 360 IS A BOOK OF VALUABLE INFORMATION, and quotes low prices on many items for which you have daily use. Send us inquiries for your wants.

CHICAGO HOUSE WRECKING CO.,
West 35th and Iron Sts., CHICAGO.



Wrought Iron
LIGHT WEIGHT PIPE
A chance to save 50% on purchases
We are offering for quick acceptance, 1,000,000 feet of good lap welded, Wrought Iron Pipe, sizes from 2 to 6 inch. It is in excellent condition —having new threads and new couplings, and is in long lengths.
3½ inch, per foot, 13c. 4 inch, per foot, 17c
At this price, WE PAY FREIGHT IN CARLOAD LOTS to all points, where freight rate does not exceed the rate to Pacific coast terminals. We can also furnish this pipe with flanges instead of screwed ends.

SELDOM through the years does this journal cite the statements of its correspondents or readers, but the general manager of one of the largest enterprises in Mexico makes a brief statement so precisely in line with the province of the MINING AND SCIENTIFIC PRESS that it is quoted. He says: "While I have not time to read many technical papers, must say that two articles in the issue of March 26th are worth to me several years' subscription." The additional statement that he finds the advertising columns to be a complete directory for his purchases, is also of value. He does the buying and his purchases are in the hundreds of thousands annually. He is a type of the man who appreciates his MINING AND SCIENTIFIC PRESS and is found everywhere. He buys and reads it because it is of value to him. He respects its utterances and looks upon an advertisement in its columns as being in good company and worthy of cousideration in placing contracts for machinery or supplies.

WHAT a nomad the mining engineer is! In Colorado to-day, in Idaho next month, thence to California, or, mayhap, Central America or South Africa. An important part of one man's work in the business office of this journal is changing the addresses of mining engineers who, in some capacity of their work, are rambliug the earth over. It is not unusual in the office where these lines are written for three or four to meet, who, since their last meeting, "had traversed foreign lands aud crossed earth's central line." Probably no profession furnishes more migratory characteristics. And thus these business pilgrims acquire a breadth of experience, a knowledge of men and things, a mental endowment of diverse knowledge that stands them in good stead the world over, and tends to mitigate the unavoidable inconveniences attendant upon this thing of forever "moving on."

Circulation and Advertising.

The Engineering News of New York, a reputable and truthful weekly contemporary, makes a statement in its issue of Feb. 11th that is notable and suggestive, namely, that while its subscription price is $5 per annum, the cost of producing each copy is about 30 cents. So it appears that it gets less than 10 cents from the subscriber for what costs it three times that amount to produce each week. To do this with 1000 subscribers would yearly briug in $5000 at a cost to the publishers of $15,000. With say 9000 subscribers, if they all paid, the Engineering News would receive therefrom $45,000 per year, while according to its figures it would have cost $135,000 to so serve its patrons with their weekly issue—entailing a deficit through the year of $90,000. Our Eastern contemporary thus forcibly illustrates the fact that the subscriber to a technical journal of high class and recognized ability gets it for considerably less than it costs, for about one-fourth what he would have to pay were it not for the other important factor in the publishing business—the advertiser. It is the advertisers in the Engineering News that enable its publishers to furnish its readers for $5 what it costs them $15 to produce. This is relatively true of several other publications. In the issue of Sept. 5, 1903, this journal commented on the same fact concerning itself. In that article it was stated that: "Such a publication as the MINING AND SCIENTIFIC PRESS could uot be placed in the hands of its readers at a cost to them of less than 6 cents per issue were it not for the advertising patronage, and it is equally manifest that in buying from those who so advertise herein the reader really beuefits himself iu more ways than one, for beside the consciousuess that he is dealing with reputable firms, it is to be borne in mind that it is those firms who make it possible for him to get such a journal for $3 per year; for, as stated, without the income received from advertising, this journal could not be issued for any such amount and continue to maintain its high standard of technical excellence. Of course, the advertiser doesn't place his advertisement iu this paper for philanthropic reasons, or just because he wants to have our readers regularly supplied with even so good a publication; he advertises for the profit its wide circulation brings him; for in no other way can he get so great a hearing at so small a cost, he being assured profitable publicity. But it is manifest from the above that it is of mutual interest to buy from firms who advertise. If what they have wasn't good they wouldn't or couldn't advertise it in the MINING AND SCIENTIFIC PRESS."

How mutually interdependent those things are is illustrated by the further fact that in the matter of paper, postage, press work, etc., the more copies of a journal that are printed the more it costs to get out that issue, and yet if the journal has not a great and increasing circulation it can not be a profitable medium for the advertiser. Hence our New York engiueering contemporary and similar high-class journals must maintain and augment their circulation, however costly that may be, or suffer a loss of advertising patronage that would be fatal to continuity of the high standard set.

This leads to a further line of thought: Manifestly, as the value to the reader depends upon the character of the material furnished, and as that costs the publisher considerably more than he gets from the reader, and as this deficit and a fair profit must be made up by advertisiug receipts, it is essential that there be no waste circulation; it is requisite that the subscribers be of a class who are intelligent and of purchasing capacity. The kind of readers that have to be bought with "premiums" and coaxed to buy the paper by offers of something else with it are not the kind who are sought by advertisers. Nor are they sought by a publication that manifestly depends for the contiuuity of its successful life on its ability to create and secure profitable business for its advertisers, and that spends sufficient to furnish the kind of matter that is wanted by practical men who look to such a journal as a valuable element in their daily lives.

Giving and Getting Credit.

Among the results of general prosperity has been the general cheapeuing of credit, so that the maker and dealer of mining machinery and supplies has under stress of competition been accorded credit to an uusual degree. Time was when a miue operator wantiug a stamp mill or a complete hoisting plant had to put up a good round sum in advance and give satisfactory guarantee that the rest of the purchase price would be forthcoming upon completion. That rule still largely obtains, and even now the complaint is sometimes made by an unbusinesslike miner that the maker and vender of machiuery docsn't want to share the smallest part of the risk, but must be given assurance of payment in full before the work is begun. But, waiving the obvious answer to that complaint, it is manifest that the old rigidity along those lines is fast softeuing and that credit is considered as expediting and extending business, one ready argument being, "if I don't do it my competitor will." The credit system in that or any department of business is liable to misuse. It is to be constantly borne in mind that a sale of merchandise is theoretically an exchange of goods for money, and to be a spot transaction. The buyer, when not paying cash or its equivalent, stands in the attitude of a borrower. The agreed value of the machinery he gets is a loan by the seller to him. There is no real difference between loaning a man $10,000 cash for six months and letting him have $10,000 worth of machinery with the expectation of getting the mouey for it in six months, except that if a manufacturer loaned the $10,000 he would have to have a note, and interest specified, and good endorsemeut or collateral security for its payment; while in the case of the transfer of goods he ofttimes has to "take his chances." It would be a good rule to observe not to credit a man for merchandise to whom you would not loan money.

It would be better all around if the losses entailed by abuse of the credit system could be minimized, for were it not for such loss the manufacturer and veuder could supply his machinery cheaper, and the mining industry would in the main be benefited. It is not suggested that credit be abolished, for individual requirements and the stress of competition would not admit of such a thing even if it were desirable, but it is suggested that there should be a clear idea of the worth, value and importance of credit; that credit is in danger of being made so cheap aud so easily obtained as to be held in light esteem. Of course every seller of mining machiuery, or of auything else, aims at the maximum of sales with the minimum of loss, but he will do well to remember that he has his own credit to keep up, and that it were better to lose a probable customer and possible profit than to lose the profit and the cost of the merchandise and the customer too. A lot of doubtful accounts are poor assets, and credit, like any other good thing, may be so abused as to wreak irreparable injury on him who gets it and him who grants it.

As requisite as to know how to make good machinery is knowledge of whom to trust. There is no one more honest than the miner; no one more desirous to pay every cent of every obligation he has assumed, but that man is often his best friend who kindly declines to permit him to place himself in a position of debt from which he may find it difficult to emerge. Credit is of use and cannot be eliminated from business transactions, but in the final crux credit is but auother name for confidence, and he who gets and he who gives will agree that it should not be made too cheap nor too common.

CONTINUAL progress and improvement is the constant aim of the up-to-date engineer. In this issuc is one of the latest developments in the manner of layiug out transition curves for railways. To present the subject logically, the author has shown the manner in which his results are derived. The busy surveyor has little time for digging through abstruse mathematical discussions, yet by going to the end of the article examples and methods of using the accompanying tablcs will be found, and will enable the surveyor to apply an accurate and rapid method of computing this important form of curve for all cases likely to occur. The article, although severely techuical, is deemed of sufficient importauce to warrant detailed reproductiou, as a matter of permanent record and reference in years to comc,

CONCENTRATES.

A 16-CANDLE POWER incandescent lamp would roquiro about 65 watts per hour.

✣✣✣✣

CHRYSOPRASE is a variety of chalcodony, tho apple-green color being due to nickel oxido.

✣✣✣✣

THE quicksilver flasks used by the Almaden, Spain, mine are furnished by a Spanish firm at 6.10 pesetas per flask. A poseta is 19½ cents U. S. gold.

✣✣✣✣

IN the California oil districts it is estimated that about 20% of the sand is oil, and that 80% of the oil contained in tho sand is susceptible of recovery.

✣✣✣✣

WHEN air is compressed to one-fourth its volume without loss of heat it has a pressure of eighty-nine pounds per square inch, or sixty pounds without heat, isothermal.

✣✣✣✣

"FOSSICKING" is an Australian mining term applied to crevice and bedrock placer mining: also to working out pillars of abandoned claims, and to the working over of old dumps for gold.

✣✣✣✣

SAND may be all right, as averred, for scouring scale out of a boiler, but unless the fact is strongly proven there will be considerable justifiable unbelief. The remedy would seem to be worse than the disease.

✣✣✣✣

EXHIBITORS at the St. Louis Exposition will have to pay $10 per horse power per month for power, the charge in each case to be based on the motor capacity installed by the exhibitor, and irrespective of the amount used.

✣✣✣✣

THROUGH an 8-inch pipe, 8000 feet long, the intake and discharge ends of the pipe being submerged, there being a head of 160 feet, there will flow, theoretically, 967 gallons water per minute—in practice about 800 gallons per minute.

✣✣✣✣

REMINGTONITE is a hydrous carbonate of cobalt, occurring in rose-colored incrustations, soft and earthy. It was first discovered in a copper mine near Finkshurg, Carroll Co., Md., and was recently reported found in the Standard mine, Baker Co., Or.

✣✣✣✣

PHOSPHORITE is a concretionary and partly scaly variety of the mineral, apatito, which occurs notably at Estremadura, Spain. Apatite is of two kinds—fluor-apatite and chlor-apatite—being a phosphate of calcium with either fluorine or chlorine.

✣✣✣✣

ANSWERS to a number of questions are necessarily deferred, it being impossible to so far get accurate and authoritative detail in reference thereto. It is desired that in all cases of inquiry the data accompanying inquiries be in detail and as complete as possible.

✣✣✣✣

THE ordinary steel tape used by engineers is graduated under a tension or pull of ten pounds. Hence a difference of ten pounds in the pull exerted upon the tape (or a difference of 31½° F.) would produce a variation of ¼ inch per 100 feet of length in the measuring line.

✣✣✣✣

MALLEABLE cast iron is all right for pipe fittings or railway supplies, but is not fitted for heavy engineering, mining or structural work. Malleable coke iron is the principal material used in its manufacture. It may be produced in the cupola, reverberatory furnace or open hearth.

✣✣✣✣

RUTILE is not a metal, but a mineral—titanium dioxide ($Ti O_2$). It is reddish-brown to red in color; streak pale brown; transparent to opaque: hardness is 6 and specific gravity to 4.2. Rutile crystallizes in the tetragonal system, and sometimes contains iron. It is used in manufacture of certain qualities of steel, also for coloring porcelain.

✣✣✣✣

IT is not practicable to give precise data on the relative values of different fuels, but figures furnished by one who has made the subject one of special study show that for 1 cent coal at $12 per ton would furnish 23,000 units; wood at $10 per cord, 27,000 units; oil at 12 cents per gallon, 12,000 units; coke at $10 per ton, 24,000 units; gas at $1 per 1000 cubic feet, 6500 units.

✣✣✣✣

A STRAIGHT sale of the company's property would be disposing of it for cash or its equivalent, and after paying all outstanding obligations a division of the net receipts among the stockholders, pro rata. Where the company disposes of its properties for stock in another company, the stock not being convertible into cash, it would be more an absorption than a "sale."

✣✣✣✣

PRODUCER GAS is formed by passing steam and air through a thick bed of coal. In this way all the coal is consumed, the greater part of the carbon being converted into carbon monoxide. There is no resultant coke, nothing but ash. Sulphate of ammonia is produced as a by-product. A ton of coal that would yield 10,000 cubic feet illuminating gas will give 140,000 cubic feet producer gas.

SPERRYLITE is an arsenide of platinum ($Pt As_2$) and is not known to contain radium or vanadium. It is the only known native compound of platinum, and its specific gravity is 10.6. Vanadinite is a double chloride and vanadate of lead—(Pb Cl). $(Ph_4 (VO_4)_3$. Endlichito is a variety of vanadinite in which a portion of the vanadium has been replaced by arsenic. Vanadium is not an essential constituent of the uranium minerals, carnotite and uraninite, which are radio-active; and so far as known, vanadium minerals do not contain radium.

✣✣✣✣

IN the blast furnace manganese oxido acts very much the same as iron, but makes the slag more liquid and more readily fusible. When manganese is in abundance it is the practice to make a slag containing little base. In some districts slags containing large amounts of manganese run high in lead and silver; in other districts similar slags run low in lead and silver. This difference probably represents the variation in practice of the smelter managers. Where oxidized copper ores are to be smelted, it is desirable to employ as little barren flux as possible.

✣✣✣✣

RUBBER CONCENTRATOR BELTS should not be allowed to remain in packing boxes. If extra belts are kept on hand in the mill or storeroom, they should be hung on a roller or a frame of some sort, and turned occasionally, as rubber, when not in use, tends to become hard and brittle (particularly along lines of folds). Where a mill is hung up for any length of time provision should be made to set the machines in motion occasionally, so as to move the belts. In such cases, also, the belts should not be kept as taut as when working.

✣✣✣✣

ORE BODIES are rarely of the same age as the rocks in which they occur, and in some instances there is a great difference. Ores found in the Silurian rocks, such as those of the Cambrian, in South Dakota, were evidently formed not earlier than the close of the Cretaceous. Ore bodies contemporaneous with the rocks in which they are found are of restricted occurrence and include certain gold-bearing conglomerates, beds of bog iron ore, calcium borate, gypsum, rock salt, etc. Some deposits of magnetite and chromic iron, the result of magmatic segregation, may also be included in this class.

✣✣✣✣

OPAL is amorphous silica. Only those varieties showing iridescent colors—the fire opal—are valuable. Some opals lose their brilliant colors on exposure to the light. The cause of the brilliant play of colors is a subject of discussion. Some authorities believe them to be due to included cavities; others think them due to their curved lamellæ, whose refractive powers differ from the remainder of the stone. These are supposed to have originally existed in parallel position, but have since been subjected to strains due to movement of the inclosing rocks; these planes have been bent and broken, producing the color effect so much prized.

✣✣✣✣

WHEN drilling with machine drill 45 to 50 feet of holes per machine on a shift is considered good work in hard ground. In the same ground men should make with hand hammers about 7 to 8 feet per man. Drilling with machines is always cheaper than by hand, except in those countries where labor is very cheap. There occasionally the labor, though inefficient, is cheaper than machine work. Machine drilling costs from 12 to 25 cents per foot according to rate of wages, cost of power, character of the rock, and to no small extent on the treatment the machine receives at the hands of the runners and chuck tenders.

✣✣✣✣

MANY big mining companies now have a geologist on their staff, the same as a consulting engineer or a manager, and his employment is an economical matter, for he can save the company his salary over and over again. Before the beginning of development work it is his business to have the geological conditions carefully considered, and the success of the enterprise often hinges on the thoroughness and accuracy of his work. It is but one of the phases of mining and scientific progress that is eliminating the gamble from mine work and making the result as certain and definite as any business undertaking can be so made.

✣✣✣✣

WHERE gold adheres to the bottom of an iron retort, the gold may be recovered by breaking out the portion to which the gold clings and treating the pieces in nitro-hydrochloric acid (aqua regia), made of two parts hydrochloric and one part nitric acid. When the whole has been taken into solution the iron may be thrown down as a flocculent precipitate in the form of ferrous-hydrate. The solution is then filtered and the gold precipitated from the filtrate by addition of ferrous sulphate, made by dissolving iron sulphate in water. The gold is thrown down in the form of a dark brownish-purple powder. This is caught on the filter or evaporated to dryness, mixed with borax and melted in a crucible in the usual manner.

✣✣✣✣

GOLD is often found in loose alluvial, or wash, where there are no rounded pebbles or rocks present. This is particularly the case in desert regions, where the rocks disintegrate rapidly, producing a mass of loose material, mostly angular, and this is washed down by the infrequent but heavy rains occurring in such regions, and the finer material is blown about by the winds, the gold from neighboring veins or rocks being buried in the debris. The gold is also usually angular, or little worn. The dry washers are familiar with this class of gold deposit. A number of instances of the occurrence of gold under these conditions are known, where the lodes or veins from which the gold came have never been discovered. There are examples of this kind in Kern, Riverside and San Diego counties, California.

✣✣✣✣

SPHALERITE is sulphide of zinc. It is also called black jack, blende, zinchlende, mock lead, jack, etc. The name sphalerite is from the Greek, meaning treacherous. No other ore possesses such a variety of color, luster and physical appearance. In color it may be black, various shades of brown, honey-yellow, grayish, green, red or white. Its luster is vitreous to adamantine. The streak varies with the color, being usually lighter than the mineral. It is transparent to translucent and opaque. It often resembles galena closely, though containing no lead, often auriferous and argentiferous. The reddish brown or red varieties are called "ruby blende." It is coarsely crystalline to fine granular, also cryptocrystalline—that is, showing a distinct crystalline structure, but which can not be resolved into individual crystals. All varieties except the black kinds have a resinous luster. It resembles some garnet, but is softer and heavier; when treated with hydro-chloric acid, evolves hydrogen sulphide.

✣✣✣✣

MEXICAN MINERS usually work their mines in an erratic manner, but although their methods are considered primitive, they have accomplished some great engineering feats in the conduct of the mining business. Among those is the shaft of the Valenciana mine, on the Veta Madre (mother vein), which is eight-sided, 30 feet in diameter and 1320 feet deep. The first 400 feet are walled with solid masonry. Below that the wall rocks are firm and hard and require neither timber nor other support. The hoisting engines are grouped about the shaft opposite its several sides, and the cages run from top to bottom being held in position by steel cables, which, reaching from top to bottom, answer the purpose of guides. The Rayas mine shaft, on the same lode, is even larger than that above described. One advantage of these large shafts is good ventilation, which would be further improved if the shafts were partitioned into two or more tight compartments, one of them being carried higher than the others. These shafts are in the State of Guanajuato.

✣✣✣✣

THE Federal statutes clearly require that a mining claim shall be plainly marked on the ground after discovery has been made. The monuments marking the boundaries must be plain and so distributed that any person may trace the outlines of the claim on the surface without difficulty. Monuments may be set at any time after discovery prior to an intervening right, but it is to the interest of the locator to promptly define his boundaries as quickly as convenient—that is, as soon as he can possibly determine the strike of the vein or lode along the surface, and for his own protection to do this thoroughly and without unnecessary loss of time. A. may make a discovery, sink a shaft and perform $1000 worth of work. He may set up a discovery post or monument and clearly state the number of feet he claims in either direction; but if he neglects to place his monuments at the corners and center-end lines, as required by law, so that all may easily determine the exact position and boundaries of the claim, and B. locates a claim near A. encroaching upon A.'s claim, B.'s claim, if properly made (complying strictly with the law) will hold as against A.'s, who has failed to make a proper and valid location.

✣✣✣✣

IN the Rand, South African, gold mines, in breaking the rock in the stopes underground, machine drills are always used. In the case of narrow reefs the values can be better maintained by using hand labor. These narrow reefs are stoped by means of machine drills, also, which lower the grade of the ore to be sent to the mill through the increase of the amount of waste which must be broken down by this means. Efforts to supplant native labor in stoping on these narrow reefs have been tried by the use of small machine drills, light in construction, drilling a hole about the same as that accomplished by hand labor, but these have not been satisfactory. Regarding the use of machine drills underground, the white labor there is the greatest opponent to the most economical working or handling of more than two machine drills under the direction of one skilled white man with the assistance of unskilled white or native helpers. As regards shovelling the rock broken in the stopes to the levels to be trammed away, efforts are being made to supplant hand labor by mechanical appliances. In long stopes, small gravity tram lines have been put in to reduce the number of shovellers necessary to handle the rock broken. The tramming underground has been carried on by natives, as the mines had been laid out with that intention. The drives as they follow the sinuosities of the reefs are tortuous, and better adapted to tramming by hand than by mechanical means. Plans have been formulated in the equipment of new deep-level mines to install mechanical haulage on certain main levels, but even in these cases it will not entirely do away with hand tramming, as more or less of it will have to be done on intermediate levels. From the time the rock is delivered to the ore bins at the bottom of the shaft until deposited on the dumps, it is practically handled automatically in all the mines, and improvements are being effected, as, for instance, the emptying of the cyanide tanks by mechanical devices, electrical furnaces for heating drills underground, and the use of mechanical drill sharpeners.

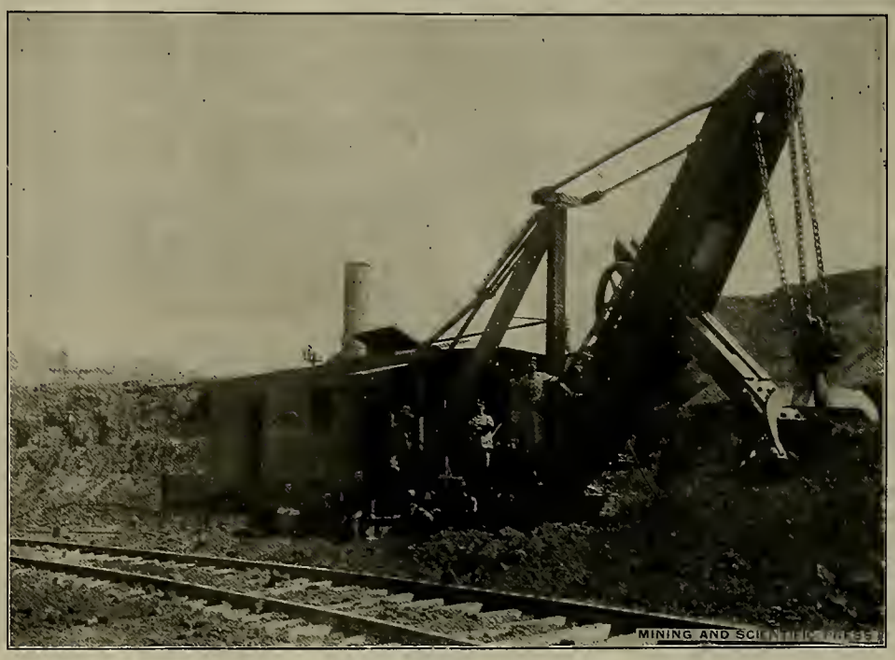
Mining Methods in the Mesabi Iron District, Minnesota.

Written for the MINING AND SCIENTIFIC PRESS by KIRBY THOMAS.

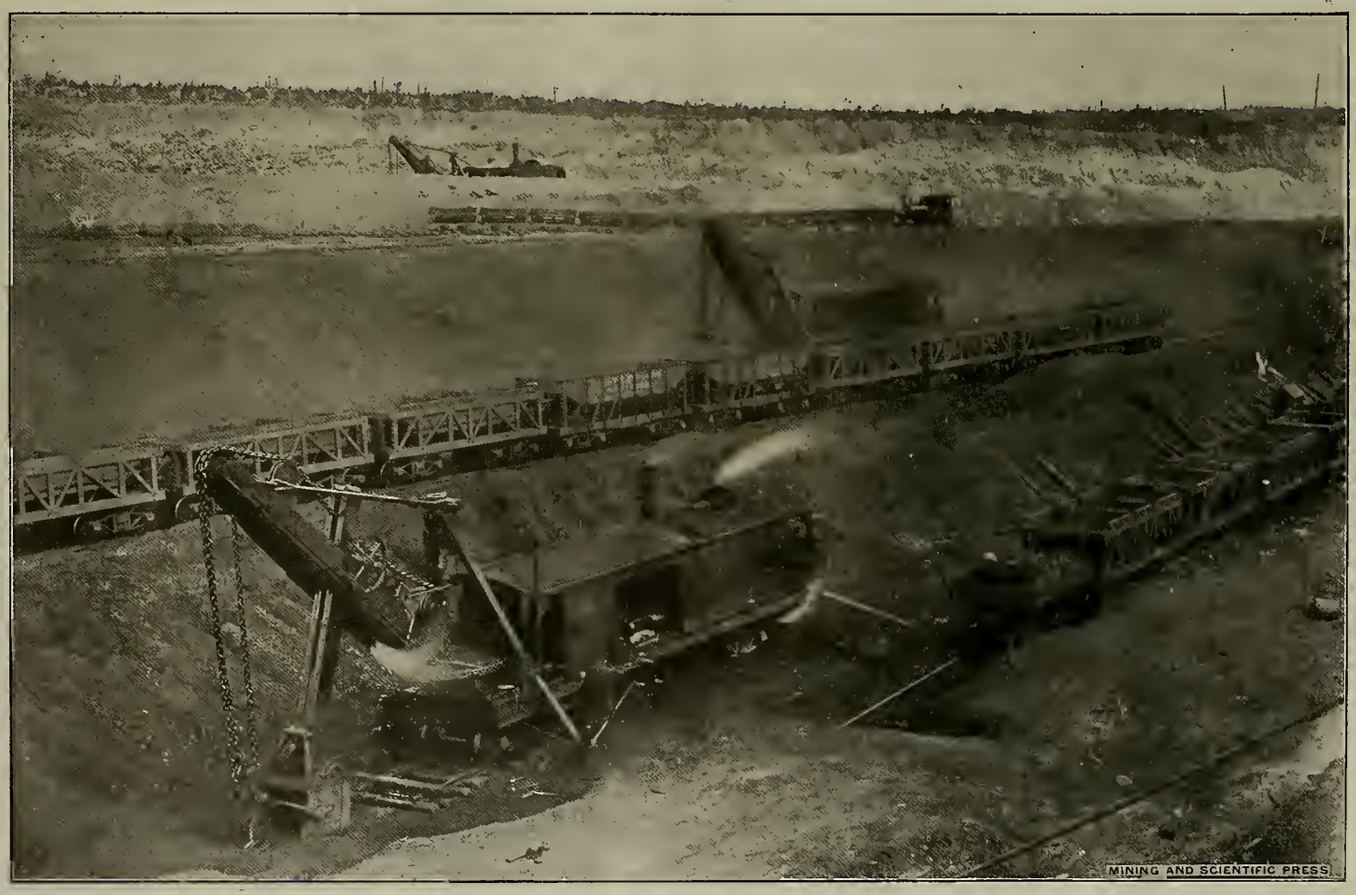
The Mesabi iron district in Minnesota has become widely known by reason of the practice of mining the ore with steam shovels from open cuts or pits. However, in recent years the Mesabi district has developed underground mining to some extent, and the open-cut methods have been modified and improved. In 1902 about 47% of the Mesabi output was from open-cut mines, the rest being mined underground chiefly by "caving" and "slicing" methods and "milling." The tendency in 1903 was to still further increase the proportion of mines operating by the open-cut methods.

The Mesabi ore is soft aud it lies in shallow troughs of large horizontal extension. The covering ordinarily is a mantle of drift material—gravel and boulders—varying in thickuess from nothing to 60 feet or more. Very recently much ore has been found under taconite layers, ofteu of considerable thickness. Taconite is the local name for the iron-bearing formation or siliceous sedimeutary rock from which the iron oxide was concentrated. In nearly all cases the ore is so friable that it easily breaks into fine material with only loosening by a black powder blast, so that it can be removed by the ordinary steam shovel.

The steam shovel mining is distinctive of the Mesabi district and was introduced there at the time of the opening of the district ten years ago. The usual rule is to mine by open cut with the steam shovel where the overburden of gravel is not more than 50 or 60 feet thick. Other considerations beside the thickness of the overlying drift enter into the selection of methods on the different properties. The size and shape of the deposit, space and facility for trackage and available dumping grounds are all determining factors. Opeu-cut mining, because of the large advance outlay for the stripping, requires more capital at the start. The theoretical rule that a foot in depth of gravel could profitably be removed for each foot in depth of ore underneath is little considered in practice.



Steam Shovel at Mahoning Mine, Hibbing, Minn.



Steam Shovels at Work in the Hibbing Mine, Mesabi Range, Minn.

THE "STRIPPING" PROCESS.—The "stripping," as the work of removing the overburden of drift is called, is usually done by contract. Several large firms are engaged exclusively in this work. The contracts are generally by the cubic yard and often extend over two or three years. At this figure the cost of removing the gravel 25 feet deep on an acre would be about $16,000; contract prices vary from 30 cents to 50 cents per cubic yard. As the contracts sometimes cover forty acres or more, the magnitude of this work can be understood.

The material to be removed varies from glacial till to coarse gravel and boulders weighing several tons. The gravel is frequently hard and is then loosened by blasting with black powder. The steam shovel is set on a portable track alongside the standard gauge track for the dumping cars. These dumping cars have an automatic side-tip dumping arrangement. They hold about 3 to 3½ cubic yards. Little "dinky" engines draw them to the dump in trains of five or six, or more if the haul is long. Iu twenty hours (two shifts) a 65-ton steam shovel will remove 2000 cubic yards. The dipper holds about 2 to 2½ cubic yards and is worked against a face usually 20 feet high. The steam shovels used on the Mesabi for stripping and for mining the ore are built specially strong and have many improvements calculated to adapt them to the special work. The haul to the dump is usually short—not more than 1000 to 2000 feet. A common practice is to strip enough ore for the mining to be started and then to strip contemporaneous with the mining. In the case of the Mahoning, however, the whole tract of forty acres was stripped before a ton of ore was taken out.

The cost sheets of operating a steam shovel are herewith given as obtained from one of the large operators. These figures apply likewise to the steam shovel working in ore, except as to the expense on the dump. The steam shovel in ore will handle nearly one-third more cubic yards than in gravel. The cost items are as follows:

WAGES PAID FOR STEAM-SHOVEL LABOR, MESABI RANGE, JUNE 30, 1903.

Brakemen, per hour	22½c
Common labor, per hour	18½c
Cranemen, per hour	32½c
Drillers, per day	$2 00
Dump bosses, per day	$2 00 to $2 25
Firemen, for 12 hours	$2 25
Head blasters, per day	$2 25 to $2 50
Laborers, per hour	18½c
Locomotive engineers, per hour	30c
Locomotive firemen, for 12 hours	$2 25
Mining captains, per month	$100 00
Pitmen, per hour	20c
Shift bosses, per day	$2 50
Shovel runner, per hour	42½c
Track foremen, per day	$2 25 to $2 50
Trackmen, per hour	18½c
Coal, per ton	$4 00.

FORCE NECESSARY FOR OPERATION OF STEAM SHOVEL.

	Per Day.
(On Shovel.)	
One shovel runner	$4 25
One craneman	3 25
One fireman	2 25
Four laborers (pitmen)	8 00
One to two track cleaners	2 70
(On Locomotive.)	
One engineer	$3 00
One fireman	2 25
One brakeman	1 85
(Drilling and Blasting.)	
One head driller	$2 50
Four drillers	8 00
(On Dump.)	
One dump boss	$2 25
Four or five laborers	9 25

Coal used by steam shovel per ten hours, 2½ to 3½ tons.

The ore forms a hard floor beneath the gravel. This floor is scrapped with graders and by hand and sometimes a layer of lean ore or taconite is removed from parts of it. This ore surface is comparatively level. Sometimes it is undulating and in some cases irregular. The work of cleaning up the floor is expensive. Generally the ore at the top face is good grade and ready to mine.

Mining the Ore.—In mining the ore practically the same methods are used as in removing the overburden, except that the ore is loaded into railroad cars by the steam shovel. The removal of the ore is in all cases done by mining companies and not by contract. The railroad furnishes the cars and the rest of the equipment is owned by the operator. The railroad takes the cars at the approach to the mine. The cars used heretofore were of 25-ton capacity and were built of wood on the plan of a box truss. Within the last year steel cars alone have been supplied for additional equipment. These have a capacity of fifty tons each. They are built of pressed steel, with air brakes and automatic dump. Many wooden cars are still used.

Each steam shovel will load seventy-five cars of ore of 25-ton capacity in ten hours. The shovel works on a face about 25 feet high. The ore is loosened by blasting, as with the gravel. The open cuts are from 75 to 150 feet deep. In no case is it necessary to use any cables or auxiliary engines to haul the loaded cars to the main track.

The system of tracks in the different mines varies considerably. The Mahoning mine has one approach and the tracks are laid on the plan of a spiral, with the lowest track in the center. The Mountain Iron mine is laid out as converging series of crescents, each outward crescent working on a higher ore bench. The Fayal, Biwabik and the Oliver use only one approach with a brauching track.

The steam shovel in common use weighs sixty-five tons. More recently steam shovels weighing 110 tons each have been in use at the Stevenson.

The contact of the ore and taconite is often irregular and horses of lean ore occur in the main mass. These necessitate some work with hand shovels, but the amount of ore handled other than by the steam shovel in any of these open-cut mines is an inappreciable percentage.

The "Milling" System.—The "milling" system of mining is used for about 7% of the Mesabi output. The ore is stripped, as in the open-cut mining, but, instead of loading direct into railroad cars, a shaft is suuk usually in the wall rock and drifts run out into the ore at a base level. From these drifts raises are cut in the ore to the surface. The ore is then broken down through the raises, by blasting and with picks, into chutes, from which it is loaded into tram cars. These tram cars are hauled to the shaft by mule power or electricity, and from which the ore is hoisted as in other underground mining. At the Fayal a steam shovel was used to dump the ore into the "mills," as the raises are called. The cuts herewith show the "milling" pits of the Fayal when the work started and later when the pits had been merged into a cavernous hole.

The percentage of the output of the Mesabi by the caving and slicing systems is nearly equal to that by the open-cut mining. This method consists in commencing at the top of the ore and working out each cut or slice, dropping the surface as the work goes on. This plan of caving the surface is used, because of the soft character of the roof, which is in most cases only gravel. A shaft is sunk as in the "milling" system, and from the base level a drift is run into the ore. Sub-levels are then driven at distances of from 12 to 20 feet and from these upraises run to the top of the ore. The ore is taken out in slices just wide enough to carry the roof while working. The ore is shoveled and tumbled into the raises, at the bottom of which are chutes which load direct to the tram cars. As each slice is taken out, the soil and rock above are allowed to cave in, and this packs sufficiently to hold up laterally with a little temporary timbering and lagging. This is repeated until the whole top of the ore body has been drawn into the raises, when the same steps are gone througb for the next sub-level. The floors of the slices are covered with boards, so as to keep the dirt from mixing with the ore and to aid in forming a roof for the next slice below. This floor under the dirt follows the ore down with each slice. This system, with some modifications, is used in all of the underground mines of the Mesabi, except at the Adams, where an adaptation of the square-set timbering plan is used in a portion of the mine. The caving and slicing system is satisfactory aud economical. Nearly all of the ore is saved. The ore itself is generally loose, so that very little blastiug is required; yet it stands up very well in the drifts and sub-levels with a moderate amount of timbering.

In the underground mines the miners workiug on company account get $2 a day. The contract miners make as high as $6 and $8 a day. The contract system in geueral use on the older ranges is coming to be more favored on the Mesabi.

In none of the Mesabi mines is the water a serious problem. The open-pit mines drain the ore bodies by drainage tunnels and pump the drainage from a central pump. In several of the large mines absolutely no pumping is needed. The Penobscot mine, in the Hibbing district, now closed down as a reserve for the steel corporation, encountered a subterranean water course which required some heavier pumps. It was found that pumping from the Penobscot drained the surrounding properties dry.

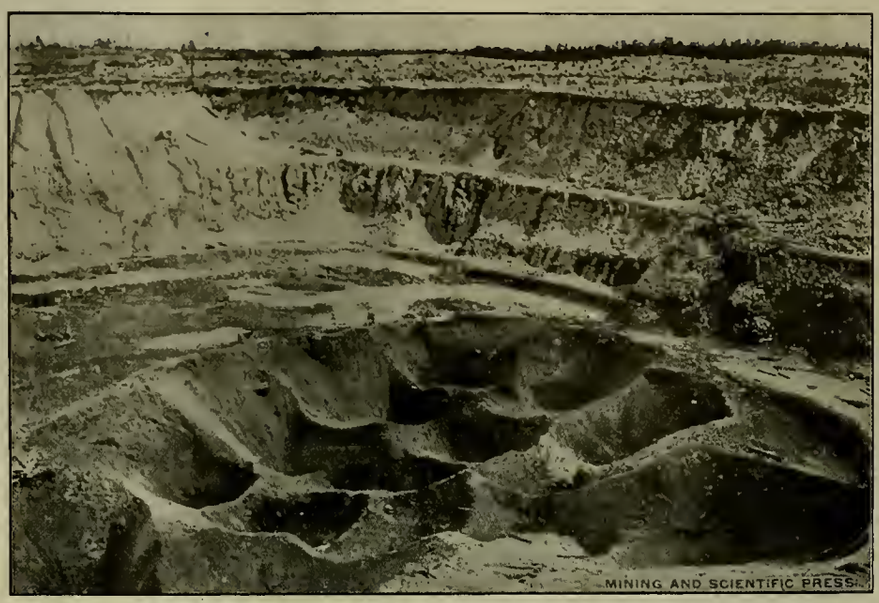
The ventilation problem is practically eliminated on the Mesabi, as the mines are comparatively shallow and usually have several openings to the surface.

A table of the depths of the Mesabi mines in 1902 shows only three over 200 feet, namely: Auburn, 218 feet; Adams, 207 feet; Spruce, 211 feet. There are five others over 150 feet deep.

On several of the shafts steel head frames have been erected, but the steel frame is not favored because of the short life of the Mesabi mines. At the present time only one mine has electrical underground haulage—the Adams. This electrical haulage is much favored aud its use is likely to be extended. In all of the mines the usual self-dumping skip is used and the ore is dumped into bins in the summer season and loaded direct into the railroad cars. In the wiuter the ore goes into stock piles, from which it is loaded into cars in the summer by the steam shovel.

Grades of Ore.—The ore in the mines does not grade regularly and it is necessary to sample closely. At the mines samples are taken in advance of the steam shovel and from the cars. Usually a determination for iron and silica can be giveu in an hour. The phosphorus takes longer. Generally the mine is sampled ahead of the work by drill holes and pits. Each mine has its own grades, which are carefully maiutaiued, as they form a basis of contracts for ore deliveries and in some cases for royalties. The under-grade ore is kept separate, if it is necessary to move it at all, or, in some cases, mixed with high grades to meet contract conditions. The grades are guaranteed, and accurate records of the grades are kept from the mine to the furnace. The texture of the ore is an element to be considered. A porous texture is desirable. The Biwabik is the only ore that is crushed. The Fayal ore is lumpy.

Probably the Mesabi mining is the cheapest in the world. This is due to the methods, particularly the open-cut mining with the steam shovel and somewhat to the large scale on which operations are conducted. In 1902 13,734,920 tons of ore were mined on the Mesabi. Last year the output was 12,820,964 tons. There were nine mines ou the Mesabi in 1903 that



Open Cut of the Fayal Mine, Showing Commencement of Mill Hole System.

Open Cut of the Fayal Mine, Mesabi Range, Minnesota, Showing Advanced Stage of Work.

shipped more than 500,000 tons. Five shipped more than 1,000,000 tons. The largest shipper last year was the Fayal, a combined open-pit and uuderground mine, putting out 1,460,815 tons. This same mine produced 1,919,172 tons in 1902. Ore was taken by rail to the lake and by water to Cleveland, where it sold for $2.75 to $3 a ton for the Bessemer grade and $2.35 to $2.65 for the non-Bessemer grades. The rail haul to the lake is uniformly 80 cents a ton. The average lake freight to Cleveland in 1902 was 75 cents. The operator pays to the fee owner royalties from 25 cents to 35 cents a ton, with frequently large bonuses for the lease. Heuce the necessity of cheap methods to make profits for the miniug compauies.

The Gold Dredging Industry.*

Written by F. W. Griffin, M. E.

Gold dredging has in fact reached the dignity of an industry. Eight years ago dredging for gold in this country was practically unknown. To-day thousands of acres of dredging land have been proved and millious of cubic yards of gold-bearing gravel are being dug each month. During this comparatively short time the development of the gold dredge has gone ahead with rapid strides until now the dredge has reached a state of perfection that has lifted dredging from an experimental basis to the plane of sound business.

The underlying reason for the general success of gold dredging is that by the use of sound expert judgment the value of a property can be ascertained to a practical certainty before any money is spent otber than that for prospecting. Whether or uot a piece of ground is suitable for dredging is determined by physical conditions. To begin with, the deposit must be the result of a great flow of heavy gravel where the drainage area has been large and the "feeders" good. The present creeks or streams which cut through a gravel deposit do not necessarily bear any relatiou to the original deposit. It must be practically flat lying, and the values must be disseminated over a wide area. You caunot dredge narrow, torrential portions of streams where large boulders abound. Where the bedrock is hard and the values are on that bedrock, the gold recovery of the dredge is materially reduced.

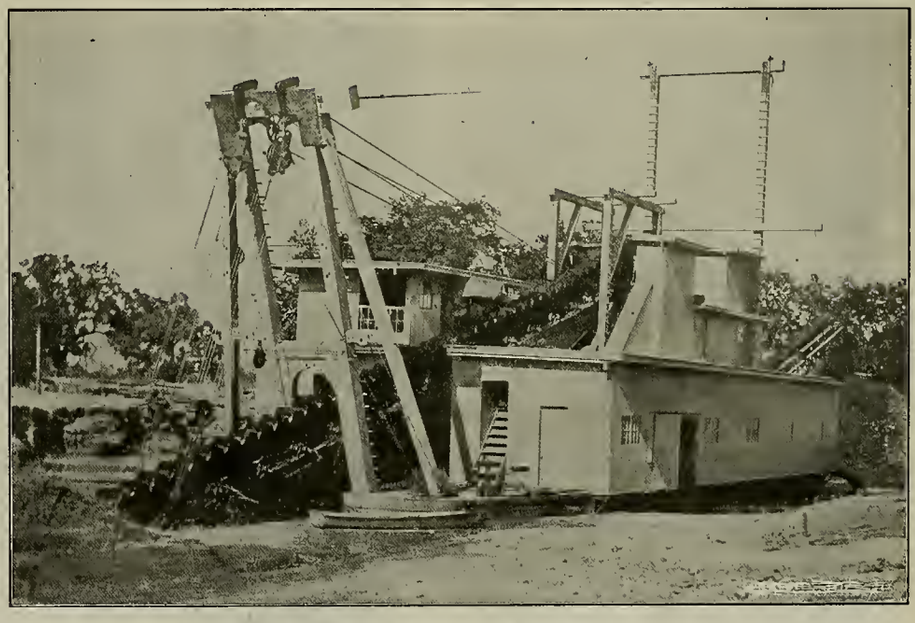
A piece of ground which fulfills the above conditions will bear investigation. Great care must be taken in prospecting, uot only in the work itself, but also in placing the holes, and particularly in drawing conclusions from the results obtained. Prospect work is generally done with a drilling machine which sinks a hole 6 inches in diameter. The test by drill is fully as accurate as the test by shaft, so far as the values obtained from the gravel prospected is concerned, but careful expert judgment must be used to reach an approximately accurate conclusion from the result of either drill or shaft. The reason for this is that oue hole to ten acres is considered close prospecting. Therefore, if ten holes are sunk on a 100-acre tract and if the total of these ten holes is divided by ten and this result is taken for the true average value of the property, it will surely be misleading. The more holes you sink the nearer you come to the true value of a property. My deduction from a great number of cases in actual practice is that a dredge will produce from 60% to 70% of the arithmetical average value shown by drill holes when the holes are placed approximately one to each ten acres of ground. This does not mean that the dredge will save more tban 70% of the values, but it does mean that the average value obtained from computing prospecting results is erroneous by 30%. If a property shows an average value of 20 cents per cubic yard, then a dredging property has been proved. This is true ouly when the drilling has been carefully done aud proper allowances have been made—further, the property must be located in an accessible place, where power is cheap. The two factors of transportation and power must not be overlooked, and where they are high the average value of the property must be proportionately high.

One of the best features of gold dredging is that the entire investment can be closely figured. The price of the property and the cost of the dredge and equipment are knowu quautities. The cost per yard of handling a defiuite quantity of gravel per month can be accurately estimated. Therefore, the commercial value of a dredging property can be accurately measured.

Almost without exception dredging is carried on, not in the rivers, but on the benches contiguous thereto. In most cases a pit is dug inland and the hull of the dredge is floated in it. Very little water is required to float the dredge and to operate it, as the water which is pumped for washing purposes comes back to the pit. The amount of water is determined by seepage and the cleanness of the gravel dug.

The dredge of the present day is the endless chain elevator type. An endless chain of buckets is carried on rollers resting on a steel ladder. The upper end of this ladder is hinged on a gantry frame about 20 feet above the deck of the dredge. The lower end of the ladder is suspended by cables, which pass over sheaves to a drum on a wiuch, so that the ladder may be raised or lowered to feed the buckets. The buckets pass over tumblers at the upper and lower ends of the ladder. The power to drive the bucket liue is applied at the upper tumbler through gears. The material as excavated by the buckets is dumped into a hopper and from this hopper is fed to revolving or shaking screens. Water uuder pressure is forced from spray pipes over the screens onto the traveling gravel. The gold-bearing material passes through the screens into a distributor, which feeds this material and water to tables provided with riffles. These tables in turn discharge into side or tail sluices, which deposit the fine tailings well behind the dredge. The coarse tailings, after being washed on the screens, pass from the screens to a conveyor, which carries these tailings 30 to 50 feet behind the dredge and stacks them 20 to 30 feet high.

A Large Dredge in Course of Construction.



Dredge Cutting Away the Surface Debris.

There are four distinct functions which a dredge must perform:

First.—Dig large definite quantities of gravel per month.

Second.—Screen aud wash all the gravel the buckets can dig.

Third.—Save the gold.

Fourth.—Dispose of the tailings.

The digging end of the machine was developed first. The size and strength of all the machiuery had to be increased to withstand the varied, changing, immense strains put upou it in digging gravel. Actual working experience has been the key to the problem which had to be met. What this experience has taught may be illustrated by the statement that the weight of the buckets alone have been increased from 500 to 1200 pounds each. Machinery on the dredge as a whole has been increased from 150,000 pounds to nearly 500,000 pounds in the larger machines, while the capacity of the dredges has been increased from 20,000 to 75,000 cubic yards per month.

It takes power to miue gravel. It takes more horse power to dig tight gravel than it does to dig loose gravel. To dig large quantities of gravel you must have large quantities of power. This question of horse power behind the bucket line is the determining oue for size of shafting and strength of digging machinery. As a fundamental proposition, the machinery must be designed to withstand a maximum pull which can be exerted by the driving machinery. If a 100 H. P. motor is driving the buckets, the strain must be figured, not to withstand the normal pull of this motor, but the greatly increased pull as the motor slows down to the stalling point. To this figure add the strain resultiug from the surging of the dredge when digging tight gravel.

Variable speed motors have been generally introduced to give better control of the machinery and to regulate the speed of the bucket chain.

In the close-counected bucket type the number of buckets dumped per minute range from eighteen to twenty-eight. In the bucket and link type the average is about twelve to fourteen.

The rated horse power of the 45,000 yard dredge is about 155; that of the 75,000-yard machine is 230. The actual average horse power used is about 100 for the small dredge and 150 for the larger dredge.

The "wear and tear" on dredging machinery is great, but the evil of wearing out one pound of material and "scrapping" nine out of every ten pounds has been corrected. The wearing parts are lined largely with manganese steel, and these wearing parts have been made readily and easily replaceable.

While the digging end of the dredge was being developed the screening end was not carr.ed on so rapidly. The dredges were digging more gravel than they could wash and screen. However, this defect has been overcome by increasing the screening area and adding more water under high pressure. The screening end as well as the digging end of a dredge

*Trans. Cal. Min. Assn.

must be designed to suit the conditions under which the dredge is to operate, the amount of material to be handled and the character of that material. In some gravel a revolving screen is better than flat shaking screens, and in other cases a combination of the two is best.

The third function of the dredge—that is, saving the gold—is made comparatively easy. In the first place, the coarse material has been removed by the screens and the finer gold-bearing sands are distributed evenly over a series of tables where the supply of water can be regulated. Immediately under the screen, where the fine material drops in thin streams, is the best place to save the gold. In general practice 85% of the clean-up is made under the screens, and the percentage of loss on a dredge is remarkably small. The gold-saving riffled area on a dredge is practically 1200 square feet.

The fourth function of distribution of tailings varies in complication with the varying conditions of the ground worked.

The distance from the water level to bedrock and the height of the bank above bedrock are determining features. Storage capacity for both fine and coarse material must be had. The main points in the distribution are to get the conveyor long enough to stack the coarse material to a height sufficiently great and far enough behind the dredge so that they will not run back. The fine tailings must be led off the dredge at an elevation which will insure storage room. Where an unusually great amount of sand is encountered, it is necessary to use a sand pump to take a portion of the fine material from the tail sluices and discharge it well over the top of the coarse tailing piles.

To be successful a dredge must be kept running as near twenty-four hours a day as possible, for when a dredge stops the producing part of a plant stops, while the expenses continue. Good judgment in the management of a dredge will minimize the time lost. Duplicates of the essential parts of the dredge should be kept on hand. All wearing parts should be provided for before hand, so that when a break occurs it can be mended with the least possible delay. Care in this regard is more necessary in the dredge than in the mill, for in the mill you can hang up one battery for repairs or renewals while the others are working; but with the dredge the most trivial accident will stop the whole plant until repaired. Still, the dredge of to-day is practically on the same footing as the mill, and the loss of time due to mechanical causes is no greater in the dredge than in the mill.

At the present time well managed dredges are making a monthly average of from 80% to 90% of the possible running time. All stops of whatsoever nature are counted, including lost time for clean-up, power shut-downs and matters outside of the actual stoppages, due to mechanical causes, on the dredge. It is the usual practice to clean up twice a month. The time lost on this account is about four or five hours per clean-up. But this time is not all dead loss, as it can be used to advantage in general repairs.

The question of size and capacity of the dredge is one on which opinion differs, but at present all efforts are bent toward increasing the capacity of the dredge. The dredge of a monthly capacity of 40,000 to 45,000 yards is more easily kept in repair, for all the parts are comparatively light. Still, the labor cost, which is one-third of the actual expense of operating a dredge, is the same in a dredge of 40,000 yards capacity as it is in a dredge of 70,000 yards capacity. The increase in power is less in proportion than the increase in number of yards handled, and, therefore, the large dredge reduces the cost per cubic yard of handling the material. The cost of repairs does not increase out of proportion. Therefore, the larger dredge is unquestionably the greater net producer. However, there is an economical limit to the capacity of a dredge. As I stated, there are three factors beside digging a great amount of material, namely, washing thoroughly, saving the values and storing the tailings. It is also true that the first cost of a dredge increases out of proportion when the size of the dredge passes a certain limit; further, the parts of the dredge are so much heavier that the difficulty of making repairs increases and the time lost from this will be greater. The expense of maintenance will also increase.

At the present time I believe that in the dredge of 70,000 to 80,000 cubic yards per month the economical limit is reached. Still the tendency is to larger capacities, and it is not at all impossible that within a short time dredges of 100,000 cubic yards capacity will be the most economical.

The average cost of handling ground with a small machine of 40,000 cubic yards capacity is, approximately, 6¼ cents per cubic yard, segregated as follows:

	Cents.
Labor	2.1
Power	2.00
Dredge supplies	0.34
Taxes and insurance	0.18
Maintenance and repairs	1.20
Sundries	0.43
Total	6.25

In the 70,000-yard machine this cost per yard is less than 5 cents.

It is useless to predict what the future has in store for gold dredging, so rapidly has the industry developed within the last two years. The improvement is steady and the field is constantly increasing. Ground is being handled to-day that two years ago was placed out of the possibility of dredges. Not only can harder, coarser deposits be handled, but the depth to which the machines can attain is constantly increasing. Under ordinary conditions a bank 20 feet above water level can be handled. One year ago the greatest depth reached was 45 feet below the water level. There are now in the course of construction on the Yuba river, near Marysville, two dredges which will dig 60 feet below the water level. Through this development, thousands of acres of ground have been added to the dredging field which a year ago were deemed outside the economical limits. As the development of the industry continues, I feel certain that tremendous areas of low-grade ground will be rendered available for profitable dredging. Instead of the field of gold dredging becoming smaller, it is growing larger and larger each year. I remember a year or two ago it was generally considered that the Oroville district was practically the only field for larger dredging operations. To-day the proved successful dredging field extends from Alaska to Mexico. In Central America, South America and Africa have dredging operations been started. In fact, in all countries where placer mining has been successfully carried on the dredge is sure to follow.

Gold dredges are operating successfully in the United States—in Oregon, Idaho, Montana, Colorado and New Mexico. In California gold dredging has been carried to its highest development. At Oroville there are twenty-six dredges operating. There are from 5000 to 6000 acres of dredging land proved and developed. A conservative estimate of the value of these Oroville properties is $4,500,000. None of the stock in the companies is for sale. On the American river, near Folsom, a good dredging field has been proved. It has not been as fully developed as Oroville, but the dredging acreage is about as great as that of Oroville. There are four dredges near Folsom, and lately new life has been infused into the camp. Plans have been made to equip the properties with dredges as rapidly as possible. Two large dredges are now nearing completion and a third is under way, and soon the Folsom district will attain the prominence of Oroville.

The Yuba field promises a brilliant future, with an acreage of 3000 to 4000. On Bear river, near Wheatland, there is a field of over 1000 acres, and new machines are being built to work it. On the Calaveras, at Jenny Lind, a large dredge has just been completed and a fine return on the investment seems assured. In Siskiyou and Trinity counties dredges are being successfully worked and soon these fields will be extensively exploited.

Generally speaking, a gold dredge will work to a depth of 60 feet below water level. It will handle a bank 20 feet above the water line. It will handle 75,000 cubic yards per month, at an expense of 5 cents per cubic yard. There is no chance of labor troubles, as two men operate a shift.

Dredging for gold has become a mechanical and a commercial proposition; as an investment it is one of the safest in the business world. It will become more and more attractive as the industry develops, and the returns demanded by capital so invested will not be greater than in ordinary commercial enterprises. Gold dredging is a real industry. Best of all, there has not been any promotion or inflation of dredging stock in California. There have been no "wild cat" schemes. The industry is young, but it is clean and strong and healthy, and bids fair to grow to great proportions.

Cyaniding Gold-Bearing Sulphurets.*

NUMBER III.

Written by S. B. Christy.

Now, this is the difficulty of the decantation process—you cannot get complete removal of your solution. There is no way to do it except to handle a large quantity of solution. The less solution I leave in my pulp the quicker I get a removal of the gold-bearing solution, and in the most favorable circumstances I had left at least one-half ton of the solution, or 50% of water, in my resulting tailings. I looked for some method of overcoming this difficulty. The filter process being not practicable, it occurred to me I might use a centrifugal machine to remove the water from the pulp. We made several forms of centrifugal machines in the mining laboratory of the University, and I made a number of experiments with this method, and I found it entirely practicable to remove the amount of water down to about 12%. The best results I got was 11%. That is, there was left in one ton of the ore about one-eighth ton of solution. This reduces the decantation coefficient and the volume that must be handled. The use of the centrifugal machine for this purpose has been patented by Mr. Sulman, an Englishman. I should have no difficulty in proving that I used the same idea practically for the same purpose in the University laboratory several years before his patent was applied for. The method, however, is I hardly think practicable for handling large quantities of ore, because the centrifugal machine is very expensive, and takes considerable power, and requires some skill to use it, but it is entirely practicable for very rich material.

There is a fourth method available, and that is upward filtration—that is, instead of trying to filter downwards, to let the solution percolate upwards through the ore. By using a very slow upward current it is possible to let the pulp settle against it, but it is one of the most difficult things to perform that you can imagine, because a stream which will rise up through this pulp adjusted to hold it in suspension when it is all loose, does not operate for a long time. In spite of the upward rising current, little particles of ore first widely separated from each other seem to form agglomerations or concentrations. They adhere together, forming little balls of precipitate which sink against that stream, and you have to constantly increase the velocity of the stream. Then channels form in the whole mass of ore, and it is extremely difficult to make the upward filtration successful. It is possible to have a slowly revolving agitator in the bottom of the tank so as to break this up and keep the channels from forming and allow the solution to percolate upward. This idea has, I believe, been patented, though the same idea has been used by Prof. Hilgard at the University of California in the mechanical analyses of soils for thirty years. I will also say that T. J. Grier, the superintendent of the Homestake mine, has invented a process of upward filtration for handling fine slimes, which is now being patented. This he has explained to me confidentially, and I have tried it, and it is one of the most ingenious things I have seen. I am not at liberty to explain it in detail, because the patent is still pending. Whether it will solve this problem commercially or not is a question, but it is extremely ingenious and looks promising.

Another method which has been used has been to attempt to precipitate the gold from the solution by electricity while the pulp is still there. I believe there are several patents on that idea. I have made a number of experiments in this direction myself, and in some cases with fine slimes which did not contain sulphurets. I have obtained good results, but in the case of sulphides the electrical action on the sulphides produces chemical decomposition which interferes with the operation. Besides that the flowing pulp erodes the gold and silver precipitated on the cathodes, and so there is a mechanical loss from this cause, and I do not feel very enthusiastic about the possible success of it as applied to sulphurets. I think, however, if one is willing to be patient and willing to put up with the handling of considerable quantities of solution that the simple decantation method is able to solve the problem to the satisfaction of all concerned.

Lastly, we have to deal with the recovery of the gold and silver from the solution. Here we need use only the well-known standard methods. We can pass a perfectly clear solution either through zinc shavings, or use zinc dust, or use electricity. The electrical method has some advantage over the other two in dealing with large volumes of a solution that come from the decantation process, and I have been working on that part of the subject for a number of years, and I have succeeded by my patented process of progressive electro concentration in recovering from such solution down to 5 or 10 cents a ton, recovering the gold and silver without refining in a perfectly pure state, .996 or even .998 fine, ready to ship to the mint without any refining charges.

I will now say a few words as to the result obtained with some ores. I mentioned the Melones as a type. There are a large number of other mines belonging to the mother lode of California of the same nature which yield low-grade sulphurets, about $25 a ton, that don't pay for working, and are practically a drug in the market. I have been able, by carrying out these ideas, to reduce these concentrates from the $25 a ton to 60 cents under conditions easily reproduced commercially. It is, of course, easy to reduce them even lower, but hardly on a commercial scale. That is a recovery of 97.6% on that ore. I deem it would be entirely practicable to do that commercially, and get it down to $1 a ton right along.

Another type of sulphurets, the Oneida sulphurets, rather richer, ran about $60 a ton. The best I could do with those was to get them down to $3.50. They were rather more difficult to treat. But that is an extraction of 92½% on an arsenical ore. These results compare very favorably with chlorination in both cases. No roasting was required, and nothing but the fine grinding and the treatment with the cyanide, as I have explained it.

I have treated the concentrates from the Treadwell mine, running about $50 a ton, and got them down to about $2.50 a ton, or 95% extraction. But I ought to say that no one should expect or think of putting up a large plant for treating sulphurets on a basis of what I have here explained, without trying experiments on a small scale very carefully and very exhaustively, first, because sulphurets, which often look very much alike, have chemical and physical properties that are not patent at first glance, and these differences often make the process very difficult. I would mention that all those sulphurets which contain tellurides in any quantity, which contain arsenides of iron and antimonides of iron and

*Abstract Trans. Cal. Min. Ass'n.

large amounts of oxidized copper ores are difficult to treat; also gold ores which coutain large silver values, say, containing thirty ounces of silver and two or three ounces of gold, are very difficult to treat. It would seem the silver and gold in those cases were associated together so that the thirty ounces of silver sulphide covered up the smaller amount of gold in such a way as to render it difficult for the cyanide to get at the gold. Silver ores in general require much stronger cyanide solution than do gold ores.

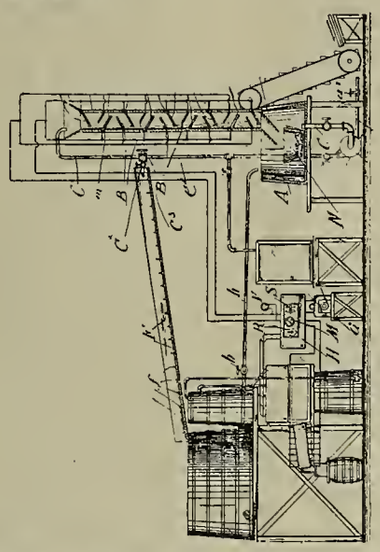
(TO BE CONTINUED.)

Mining and Metallurgical Patents.

PATENTS ISSUED APRIL 5, 1904.

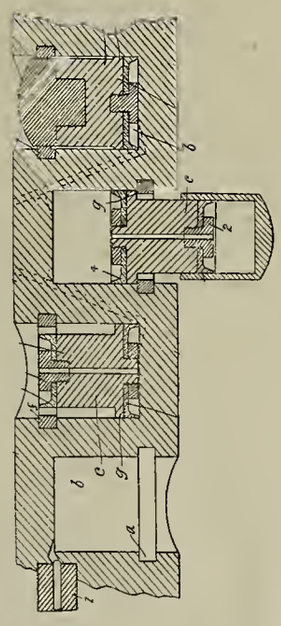
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF TREATING LOW-GRADE ORES AND TAILINGS BY ELECTROLYSIS.—No. 756,223; E. Fahrig, Philadelphia, Pa.



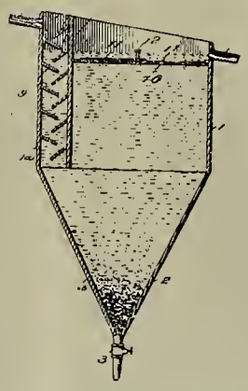
Process of treating low-grade ores and tailings by electrolysis for regaining precious metals contained in same, by grinding ore or tailings, then mixing same with suitable quantity of water and suitable electrolyte to form pulp, passing pulp by gravity between series of pairs of inclined anode and cathode plates arranged one below other, and removing from time to time precious metal deposited on cathode plates.

HYDRAULIC PRESS FOR MINING PURPOSES.—No. 756,738; A. J. Tonge, Chequerbent, near Bolton, J. Tonge, Jr., Westhoughton, near Bolton, and E. Eaves, Stockport, England.



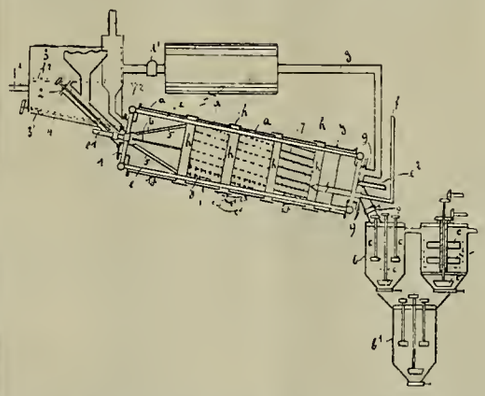
Hydraulic press comprising body provided with cylinders, pistons working in cylinders, and formed of plurality of members operating within and upon each other, means for forcing fluid to operate pistons, and stop plate slidingly mounted within groove in walls of each cylinder and adapted to limit outward movement of pistons.

ORE CONCENTRATOR.—No. 756,305; C. G. Weller, Idaho Springs, Colo.



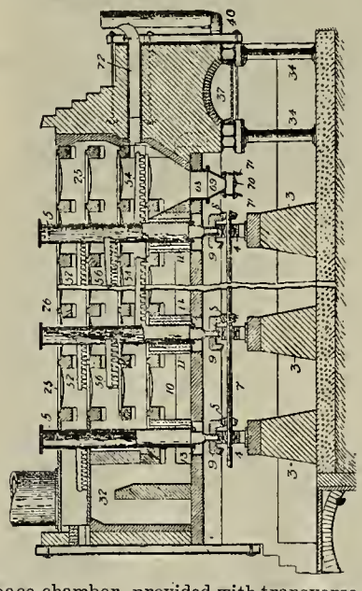
Device for concentrating ore, consisting of hollow body provided with tapered lower portion, having valved outlet and having inlet and outlet at opposite sides, outlet being at lower level than inlet, and having upper portion of inlet side vertical and lower portion inwardly inclined, a partition arranged a short distance from and parallel with vertical portion of inlet side, oppositely inclined plates projected into space formed between partition and vertical portion of inlet side of body, and alternately disposed and having inner ends overlapped, and fine meshed screen arranged near upper end of body below plane of outlet, and knocker frame applied to screen for receiving light blow when it is required to jar screen to dislodge material therefrom.

APPARATUS FOR TREATING SOLIDS, SUCH AS ORES, LIQUIDS OR GASES.—No. 756,271; P. Naef, New York, N. Y.



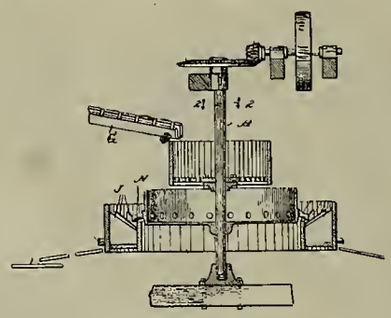
In combination with apparatus for treating liquids and solids, settling tank, inclined bottom on tank and means to run sludge from tank, back to apparatus.

ROASTING OR DESULPHURIZING FURNACE.—No. 756,485; F. J. Falding, New York, Y. Y.



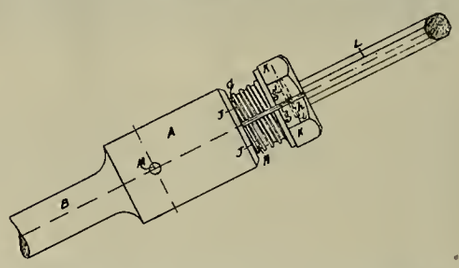
Furnace chamber, provided with transverse arches spaced apart along length of chamber and independent of each other, each having individual buck staves and tie rods, and intervening brick work occupying spaces between arches and completing furnace side walls; also provided with rotatory hollow column having hollow stirrer arms, means for creating flow of cooling medium through column and arms, and means for controlling independently flow through column and through several stirrer arms.

APPARATUS FOR DISTRIBUTING ORE PULP TO CONCENTRATING TABLES. — No. 756,327; W. Carkeek, Butte, Mont.



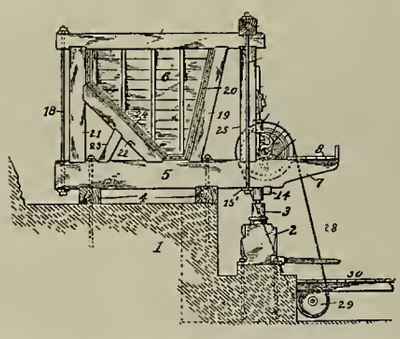
Supply pipe rotary mixer box, having perforatious in bottom, distributor chamber having plurality of openings equally spaced around periphery, series of tubes projecting diagonally downward from openings with respect to plane of rotation, series of boxes having partitions diagonally disposed with respect to plane and interposed in direction of tubes, edges of partitions being perpendicular to tubes, and outlet pipes for receptacles.

CHUCK FOR ROCK DRILLING MACHINE.—No. 756,377; W. E. Kimber, Johannesburg, Transvaal.



In rock drill chuck, body having internally threaded, longitudinally tapered hole and correspondingly tapered, externally threaded split nut, sections of nut being independent and separated, and means independent of stock of nut for holding sections thereof in assembled relation.

STAMP MILL.—No. 756,774; M. P. Boss, San Francisco, Cal.



Stamp mill having beam anchored at one end only, and having its other end projecting beyond supporting wall or column, and overhanging mortar, overhanging end sustaining counter load of working mechanism over mortar.

PRECIPITATING METALS FROM SOLUTIONS.—No. 756,211; C. Butters, Berkeley, Cal.

The improvement in process of precipitating metals from solutions, chiefly cyanide solutions, which consists in employing cathodes having surfaces of tin and anodes of lead peroxide and high density electric current.

PROCESS OF TREATING ORES.—No. 755,951; J. Smith, San Francisco, Cal.

In cyanide treatment of ores, method of rendering insoluble in cyanide solution, ferrous oxide contained in mass of moist crushed ore, by applying heat to mass in presence of air, previous to treatment by cyanide solution.

ONE of the interesting exhibits of Wyoming in the Mines Department of the World's Fair is a single piece of soda weighing 6000 pounds. It was cut from Soda lake, in Albany county, and is the largest single piece of soda ever exhibited. If made into soap of half-pound bars it would do the washing of a small family for 2000 years.

The Copper Arsenides of Lake Superior Region, Michigan.

Written for the MINING AND SCIENTIFIC PRESS.

The first production of copper arsenides, notably domeykite, was from the Sheldon - Columbia mine, near the shore of Portage lake, in Houghton county, Mich. The presence of copper arsenides on the Keweenaw peninsula has been known for some time, and it has been observed that these particular minerals are not found in the bedded deposits of native copper, but always in fissures which intersect the amygdaloidal and conglomerate beds. Thus far these veins have been observed only in connection with the lower beds near the basal members of the formations to the southeast. However, even in the smelted and refined copper of all the mines some arsenic is said to be present (though it does not seem to affect the quality of Lake copper), being a minimum in the conglomerate of the Calumet & Hecla, and a maximum in the copper from the amygdaloid beds of the lower measures in which occur the Mohawk, Wolverine, Arcadian, Sheldon-Columbia, Isle-Royale, Atlantic, Baltic and Champion mines.

In the course of development work at the Mohawk mine, near Allouez, a cross vein at right angles to the copper-bearing amygdaloid was struck, showing 12 inches to 15 inches wide, with a gangue of quartz and calcite. Samples of this ore submitted for analysis proved to be a new mineral species, and was named "Mohawkite." G. A. Koenig (Am. Jour. Science, Vol. X, No. 60,—1900) gives the following contents:

	Per cent.
Cu	61.67
Ni	7.03
CoO	2.20
Fe	trace
As	28.85
	99.75

Considerable variation has been shown by the first and principal fissure, which was cut in the north drift from No. 1 shaft. It was rich near the surface, and low grade on the fifth level, but again increased in values below that point. The width varied from 3 inches to 3 feet, and the vein was mineralized, mainly its crossings with the amygdaloid carrying copper. Mohawkite, as well as the other allied arsenides, occur massive, as well as disseminated in a gangue of granular texture. The ore is hand-cobbed and barreled for shipment to a smelter built by the Guggenheim Expl. Co. for this purpose on Hackensack Meadows, N. J., near New York City, the ore weighing 1300 to 2400 pounds per barrel. In its reduction the ordinary smelting process is not employed because of the high percentage of arsenic, but the ore is readily reduced by the pyritic method. So far as known, the nickel and cobalt values are lost, also most of the arsenic, but all of the copper is recovered. The Mohawk mine during 1902 produced about 150 tons of mohawkite per month; and during the year 1903 the sales of this mineral, according to the annual report of the company recently issued, reached value of $14,467. It is estimated the ore averages twenty ounces in silver per ton. Mohawkite is remarkable for its high specific gravity (8.05)—native copper being 8.8. When first mined it is gray in color, but on exposure to the air, tarnishes to purple or dark yellow. It has a gray streak. Three distinct veins of it were opened in the mine. The report of the Mohawk C. Co. for the year ended Dec. 31, 1903, in referring to the sales of mohawkite, says the cross fissures carrying it have gradually become barren and work has now been discontinued on them.

Of the other arsenides, the following occurrences have been observed:

WHITNEYITE.—In a quartz vein in dark melaphyr near the Mohawk mine.

FOLIATED DOMEYKITE.—At Sheldon-Columbia mine; also at the old Huron location (now the south end of the Isle Royale mine near Houghton.

ALGODONITE.—At the Pewabic mine on the Quincy amygdaloid (5000 feet higher in the geological horizon than the Isle Royale amygdaloid).

A stibio domeykite was found in the Mohawk mine, and in physical properties is not distinguishable from the domeykite of the Houghton county mines. It is free from admixtures, and its occurrence, massive. It tarnishes rapidly, becoming finally a bluish purple. Though brittle, it is not as friable as mohawkite. Hardness is 4 and sp. gr. 7.9. Before the blowpipe, the presence of antimony is detected. Koenig ("ibid"—above) says the following method employed by him will indicate its presence down to as low as 0.1% antimony: In open tube after heating molten globule for five minutes, yellow s ots appear near by with rings and patches; and farther on a copious sublimate of As_2O_3. Wash out tube in jet of water and pass H_2S into tube—ring and patches turn red and As_2O_3 turns gold-yellow. The composition is:

	Per cent.
Cu	72.48
(Fe, Ni, Co)	0.24
As	26.45
Sb	*0.78

* Varying to 1.29 as maximum.

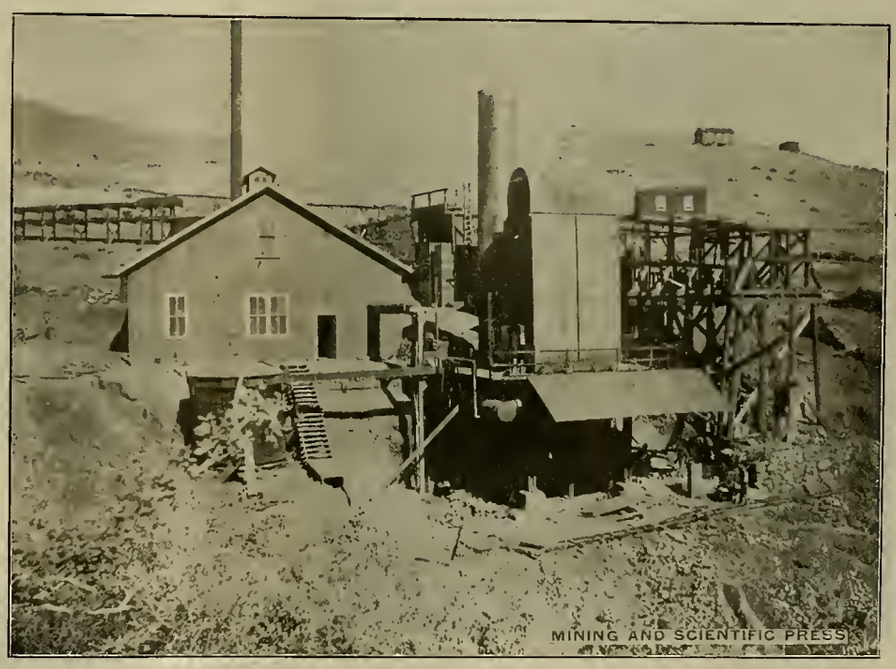
It is a typical domeykite with antimony added.

Mohawk-whitneyite is another occurrence, being, however, a most intimate mixture of those two minerals and not a separate species. In the Mohawk mine considerable masses of it occurred. Still another arsenide of copper, though not as yet known to have been found in the Mohawk mine, is algodonite. It resembles Mohawk-whitneyite, and has a specific gravity of 8.38. It has a color and texture like razor steel, and is tough, not being dented by a hammer blow, as is whitneyite. Its composition is given as:

	Per cent.
Cu	83.72
(Fe, Ni, Co)	0.08
As	16.08
	99.88

The qualities of Lake copper have a well-known standing, so much so that there is a demand for it over other varieties for certain kinds of work; and the presence of arsenic does not seem to have affected these desirable qualities, at least, not to a noticeable degree.

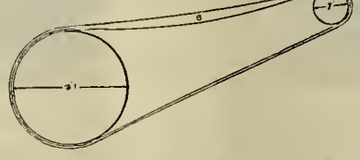
Dumping Buckets, Equator Copper Mine, Near Jerome, Ariz. (See Page 271.)



Equator (Iron King) Smelter, Near Jerome, Yavapai Co., Ariz. (See Page 271.)

Working Double Belts.

Where a belt must turn over small pulleys at high speed it is sometimes advisable to use double belts



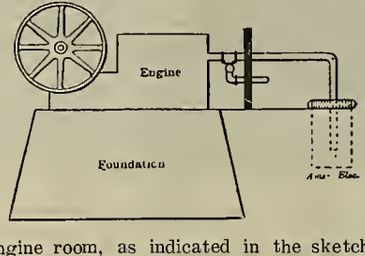
and it is claimed that two thin, wide belts will give better service than a single stiff one would.

The drawing shows how an arrangement of this kind was used on a machine operated at about 4200 revolutions. At first only one belt, a 5-inch, three-ply rubber one, was used, but this soon began to break. It was laced as loosely as possible, and a tightly laced single leather belt, 6 inches wide, placed on top. When the machine was idle the two belts remained close together; but at work the inside belt sagged on the top or loose side about 3 to 6 inches below the outside belt, as shown in the diagram.

After being in use for about two months the inside belt broke. When it was again laced up it was very tight and would run off the pulley as soon as the machine was started, showing that the inside belt should be loose and the outside one tight. In the case referred to, the outside belt traveled about 6 inches per revolution faster than the inside belt.

Home-Made Gas Engine Exhaust Muffler.

A cheap gas engine exhaust muffler consists of a piece of sewer pipe about 10 inches in diameter and 2 feet long, set in the ground just outside the wall of



the engine room, as indicated in the sketch. The exhaust pipe of the engine enters the muffler through a wooden cover, which is perforated with a number of 1½-inch holes. A branch is led off from the exhaust pipe and opens into the air, a valve be-

ing inserted at the junction of this pipe with the exhaust pipe. This is for the purpose of relieving the cylinder of back pressure at the time of starting up, and also in case the holes in the muffler cover become closed up with snow or ice between the time of shutting down and starting up. After a few explosions, the relief valve is closed. This muffler has been found to satisfactorily suppress the sound of the exhaust.

Another point which may be of interest consists of supplying a small radiator with the water discharged from the water jacket of the engine, thus cooling the discharge water, and at the same time contributing to the heating of the room. The engine to which these features were applied is a 3 H. P. machine, operated by gasoline; the radiator is made up of ½-inch pipe.

Some Mine Head Frames and Hoists.

Written for the MINING AND SCIENTIFIC PRESS by WALTER W. BRADLEY.

From time to time there have appeared in the MINING AND SCIENTIFIC PRESS illustrations of various examples of head frame construction. It is thought the accompanying examples observed by the writer will prove an interesting addition to those already published. While all three of the examples shown are California mines, they, however, illustrate somewhat differing arrangements.

Fig. 1 is that at the Cross shaft of the Utica Gold Mining Co. at Angels, Calaveras county. It is for two of the three compartments, the left one carrying a 1500-gallon water-bailing skip and the other a rock skip, the two being run in balance. The water skip has an automatically operated discharge valve at the bottom. The shaft is vertical and 1370 feet deep. The entire head frame structure is very heavy. As seen by the cut, it is a four-post affair, the two rear members acting as back braces, having a greater inclination than the front ones. The skip guides are, of course, vertical, and are braced to the front of the head frame by short timbers—the weight of the load coming on the main frame by reason of hanging from the sheave wheels on top. The enclosed structure on the farther side of the head frame contains the rock breaker and ore bins. From these bins the crushed ore is trammed several hundred feet to the Stickle 60-stamp mill of the company. The tramway track has a slight grade toward the mill, so that the car runs by gravity to the mill. The car has a brake, is side-dumping and of 1½-ton capacity. The timbers used in the gallows-frame are not numerous, but are very heavy. The corner posts are each in two pieces, spliced together. The entire structure is about 100 feet high. The only unusual feature of the construction is that the vertical shaft guides are almost wholly outside of the head frame. The plant connected with this shaft contains one of the largest installations of hoisting machinery to be seen along the Mother Lode section of California, and, as far as the writer knows, it is the only one of this type (cone drums) in the State. It is a double, conical-drum hoist, arranged to use either steam (direct-connected) or water power, built by the Union Iron Works of San Francisco. The two truncated cones are placed with their smaller bases adjacent, the small end being 6 feet 6 inches in diameter, the large end 9 feet 11 inches, with a leugth of 8 feet 10 inches between them. The grooves of each drum are to accommodate seventy-five coils of 1½-inch steel cable, or a total length of 1935 feet. The steam cylinders are 24 inches diameter with a 60-inch stroke, and the impact water wheels are 10 feet in diameter with triple nozzles. The capacity of the hoist is for raising 1500 gallons of water at rate of 500 feet per minute in balance, with boiler pressure at 100 pounds or water head of 250 feet. The block brakes, friction clutches and disc brakes are operated by either steam or water power. During the late summer and fall, when the water supply is low, the steam equipment is used.

The second illustration is of the Empire mine head frame near Grass Valley, Nevada county. The hoisting plant is in the galvanized iron-covered building at the right. It is a double-drum friction hoist operated by water power. The shaft follows the vein

Fig. 1.—Head Frame Cross Shaft, Utica Mine, Angels, Cal.

Fig. 3.—Head Frame Tesla Coal Mine, Tesla, Cal.

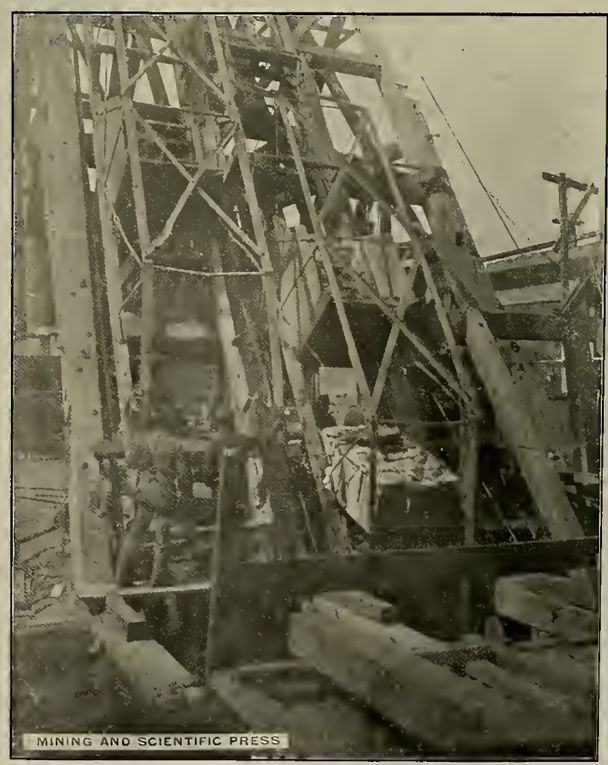

Fig. 4.—Collar of Shaft, Tesla Coal Mine, Tesla, Cal.

formation down at a dip of about 30°. In the head frame are two bins, the lower one for waste rock and the upper for ore. Below the highest bin is a No. 5 Gates gyratory crusher, through which the ore passes to a third bin, from which it is trammed in a side-dump car to the 40-stamp mill. The skips dump automatically. The shaft is down about 3000 feet on the incline. The back braces of the head frame are set steeply, but the resultant strain falls within the structure. There are side braces, also, to minimize vibration. The entire structure is substantially built. The presence of the rock bins necessitates, of course, more timbers, in the way of ties and braces, than would otherwise be required.

The "A" type of frame is shown in Fig. 3, as built at the Tesla coal mine—Sau Francisco & San Joaquin Coal M. Co.—at Tesla, Alameda county. The shaft is of three compartments, the west one—the photograph was taken looking west—being used for sinking. The auxiliary hoisting equipment is on the right and on the hanging wall side of the shaft. Four steel cables are used as side guys for the head frame. The legs are each of a single stick of timber, the front ones being reinforced by an extra piece bolted on top of each, extending about two-thirds of the way to the top from the collar. The back legs are reinforced by shorter pieces. The angle and cross-braces are all of fairly heavy timber. The shaft pitches into the hillside, following the dip (57°) of the sandstone beds in which it is sunk, and being about 200 feet from the "Eureka" coal bed—in which are the principal developments—on the hanging wall side. The formations adjacent to the coal veins being mainly sands, shales and sandstones, make heavy ground to hold.

The cages used have a length sufficient to accommodate three cars; but at the time the photograph was taken the middle deck was boarded on the sides and bottom and used for handling men, tools and timbers. The width of track for these cages is 5 feet, and the rails for the mine cars which run between have a 25-inch gauge. At the surface and at each level underground the mine-car rails curve over onto the level and run out horizontally. In Fig. 4 may be seen a car being loaded onto the cage. There is a bumper roller across the cage, against which the back of the car rests in going up and down the shaft. The cage is built of steel channels and angles, riveted. At each station underground there is a false, narrow gauge track on hinges, which is swung into place for the mine cars to pass. In descending, the gates are closed and the cage is stopped just below the station. Then the gates are opened, and, with two short, quick raises by the engineer, first the upper and then the lower car is thrown out onto the level. From the collar of the shaft the cars are pulled to washer or dump by a mule; but underground, electric haulage is used. Levels have been established at 200, 400, 600, 800 and 1000 feet. The hoist is operated by steam, direct-connected, and has double cyliudrical drums 7 feet in diameter. The speed of hoisting is 1100 feet per minute, at fifty revolutions per minute, and eighty-five pounds steam gauge pressure. The steam cylinders are 20 inches diameter, with 60-inch stroke.

The cars containing waste are run out onto the dump and emptied of their loads by the automatic tipple, shown in Fig. 5. The bed of the tipple is made

Fig. 5.—Automatic Tipple, Tesla Mine, Cal.

of heavy iron plates, and after the loaded car is run onto it, it is automatically tipped, being thrown out of balance by striking the curved ends of tipple, and the load falls out. The change in center of gravity brings the car and tipple back into the horizontal position. There is a projecting bar of steel over the tops of the carwheels to hold the car in place when tipped. The end door of the car is opened automatically, the curved bar seen on the side of the tipple throwing the latch. Doors on top of the car keep the material from falling out while in the shaft.

Where rapid hoisting is required and large quantities of material are to be handled, recent engineering practice—notably at the diamond mines and on the Rand in South Africa, at the copper mines of the Lake Superior region in Michigan and elsewhere—has demonstrated the economy of hoisting with skips over the cage system. In view of this, it would seem advantageous at these coal mines, where a large daily output of a low-grade product like coal is to be handled, to use the skip system instead of cages. Pockets would have to be cut and bins built at each level and bins arranged at the head frame. This, of course, would necessitate some changes in the accessory arrangements around the shaft—a higher head frame might be needed—but the cost of handling would be so reduced and so much larger capacity obtained, that the cost of making the alterations would soon be more than regained.

Comparing the head frames illustrated herewith with several types previously presented by the MINING AND SCIENTIFIC PRESS (e. g., July 11, 1903, p. 21; July 25, p. 47; Aug. 22, p. 109; Feb. 6, 1904, p. 94; March 19, p. 190), and also in the frail structures used in the fluorite, lead and zinc mines of Kentucky and Missouri (see Feb. 7, 1903, p. 81, and Feb. 14, p. 101), they appear unnecessarily heavy. True, they had better be massive and too strong than too weak for their work. But, if the actual breaking strength of the kind of timber to be used be considered, it will be found that much smaller timbers can be used than are ordinarily seen at most Western mines.

A Millman's Experience.

Written for the MINING AND SCIENTIFIC PRESS.

"If you will attend to the repairs I'll help the 'boys' clean up." Thus spoke the boss after I had shut down the mill for a general cleanup. The "boys" referred to were the leasers whose ore we were working.

I want to say, first, that though the method (?) followed at this mill is, perhaps, an exception, it is by no means a rare instance of the laxity of a host of superintendents, for during an experience of eight years I have found innumerable instances where the workings at this mill were followed to a greater or less extent. Only the other day I was talking to a millman of twenty-five years' experience, and who has just returned from Nevada after a couple years' cruise. After relating the incident to follow he remarked: "That's nothing. I have been going through double that since I have been in Nevada."

When my partner and I came to this mill it was rubbish and dirt from the rock breaker to the vanners.

From the cam shaft boxes and the top of the lower guide blocks we scraped two tomato cans full of old axle grease; from under the feeders and plate tables we got half a ton of ore.

The feeder worked whenever it took the notion. The mortar was fed by the vibration of the feeder (due to the falling stamps), which shook the ore into the battery.

The apron plates sagged at least ½ inch in the middle, not to mention the numerous ridges caused by the floor of the table warping.

The pulp was carried from the plates to the vanners by a launder some 2 feet wide. From the battery floor during the first cleanup we made of the mill I am sure we got at least $25. "That don't amount to much," the boss said, "as it has been accumulating for years."

The vanners we actually dug out of the sand. The bearings were solid blocks of pulp and grease and the frame shook like a runaway engine. One vanner had been shut down, as the belt had run too far to one side and would not "come back," we were told.

As we have to do our firing, we examined the boiler and took from the same a wheelbarrow and a half of scale and muck.

Well, we have got the mill in pretty good shape, though it has taken some time. When we were ready to run we asked the boss what size screen to put in, and he said: "You might put in the 30. No, put in the 40-mesh." Later: "No, put in the 30. I guess that will do." He had been working this ore three or four years and did not know exactly what size screen to use.

We never got anything we ordered unless something broke, and then only enough material to repair the break. Why do some superintendents imagine that every article purchased for the mill eats into the returns?

"Boys, you'll have to cut down expenses here in the mill," while at the mine waste is visible at every turn.

But I started out to relate an instance, and not to kick.

I stood on the vanner floor, leveling up one of the machines, while the boss and the boys made the cleanup. The boss took out the screen and set it on the floor with a "dull, sickening thud" that nearly jarred the tacks out, not to mention the amalgam adhering to the frame. A board was then thrown across the plates and the dies pried out with a crowbar, and if the board wasn't wide enough to allow him to step back far enough to get the proper leverage he stepped on the plates instead, which, mind you, had not been cleaned yet. The dies were put into a galvanized iron tub with holes in it big enough to put your finger in. These were washed by throwing a couple of buckets of water at them from a distance of 6 or 8 feet. The pulp from the battery was shoveled into old oil cans, and whenever a piece of hard amalgam was found it was passed around for general inspection.

One weighed it, another broke a piece off to see if the gold was fine or coarse, and the third let it fall on the floor.

The pulp was all panned by hand—no magnet to remove the iron, no muller to clean the amalgam.

"Quite useless," he said, "as we get it all in the melting."

The amalgam is finally collected and ready for weighing. The scales consist of an old pair of tip and balances, with only 15-ounce weights, so the metal has to be weighed in lots.

The amalgam is put into the scoop by grabbing a handful and carrying it across the room to the scales. All hands assist in this.

After this the amalgam is put into an old, rusty retort, sealed and placed on a roaring fire. In fifteen minutes the retort is taken out and the cover removed. The room is white with mercurial vapor, and one fellow flees to save his "teeth."

The retort is overturned upon a piece of sheet iron and lo! the pot metal is visible—or is it a lump of dirt?

All jaws drop two points at this juncture.

"But she'll be O. K., boys, when she is melted. Shines like a twenty."

The pot metal is broken into pieces and placed in a crucible with the necessary ingredients for a flux.

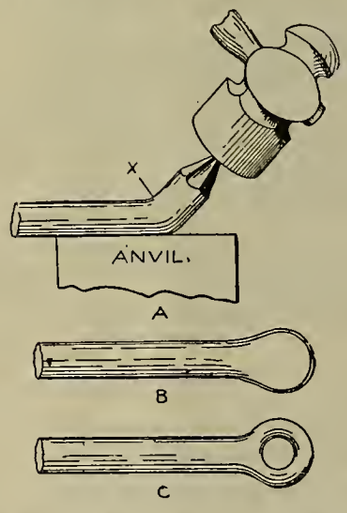
The crucible and its precious contents are taken to a portable forge and the "gang" proceed to get up steam. After half an hour's arduous work the belt breaks and they stop for repairs. But the belt is too old; in fifteen minutes it breaks again, and then again, and finally, for fear it won't hold out much longer, the metal is poured into the mould. The mould, in turn, is quickly dipped into cold water and a slight explosion scatters the slag. The bar is taken from the mould. It is crystallized—and is it gold or iron?

"We will send it to the mint and have them fix it. It will be O. K. then." From the slag and floor we cleaned up about $40.

"It's all easy when you know how."

How to Forge an Eye.

The following is a good method of forging an eye for chain-hooks, braces, eye-bolts, etc., when the whole strength of the rod is wanted in the eye: Take a soft heat on just the end of the rod (using a



hammer of good weight), point it a little, and bend down over corner of anvil. Next turn the point up and strike as in Fig. 1, A, so as to upset the bent part down even with the rod, as in Fig. 1, B. Take care not to get a cold shut. Turn it over and punch as quickly as possible, rounding up on the horn of anvil. With a little experience, one can make a good, strong job, and at one heat.

IRON changing from molten to solid state expands, but, having solidified, it contracts as the temperature further decreases. This action has been utilized in the artificial manufacture of diamonds, and attempts made to explain the origin of the diamond as occurring under similar conditions. Particles of carbon were enclosed in molten iron, outer surface of mass chilled and molten interior allowed to solidify slowly. The pressure thus produced and the temperature caused formation of minute diamonds from the carbon.

Cornu's Spiral as a Transition Curve.*

By D. N. Lehmer.

1. Cornu's spiral, which is of such fundamental importance in the theory of light,† has the remarkable property that the radius of curvature at any point is inversely proportional to the length of the curve up to that point, measured from a fixed point. It is this property that makes it of value as a "transition curve," which is a curve intended to diminish the shock experienced hy a train in passing from a straight track to a circular curve, or from one circular curve to another of different radius.

2. Various other curves have heen considered in this connection, the most successful heing the cuhic parahola, which within the range of ordinary practice agrees very closely with the spiral. The methods proposed for laying out the spiral in the field have been so complicated that the ordinary engineer will not undertake the work. The method herein described has heen in use for some years on the Burlington and Missouri lines, where the curve is known as Green's spiral. It was introduced on that road hy Mr. E. L. Wooley, one of the locating engineers, who prepared a tahle in connection with it hased upon a discussion hy Mr. D. M. Green of the R. P. I. at Troy, N. Y. The tahles given herewith are largely reproductions of the B. & M. tahles, computed for that road hy Mr. F. A. Jones. For the theory of the curve I am largely indehted to Professor O. V. P. Stout of the University of Nehraska.

3. As in staking out a circular curve it is customary to use a suhchord of constant length, usually 100 feet, unless the curvature is very sharp, so in staking out a spiral a suhchord of definite length is chosen. If it is desired to pass from a straight track to an N-degree curve, N of these suhchords are taken. At the end of the first chord the radius of the spiral is made equal to the radius of a one-degree curve, then since the radius of curvature is to vary inversely as the length of the curve at the end of the second chord we shall have the radius of a two-degree curve (very approximately) and so on.‡‡

4. In running a spiral from a tangent to a circular curve the initial and final points are denoted hy P. S. and P. C. respectively. In running a spiral from a circular curve to a tangent the initial and final points are marked P. S′. and P. T. respectively. Denote hy l the length of the spiral measured from P. S. to any point and ρ the radius of curvature at that point. Then hy the definition of the curve

$$\rho = \frac{1}{2\,K\,l} \qquad (1)$$

Also if $\triangle$ is the angle hetween the angle at P. S. and the tangent to the spiral at a point distant l along the curve, we have (Williamson's Calculus, p. 286)

$$\frac{d\triangle}{d\,l} = \frac{1}{\rho}$$

or from the equation (1)

$$\frac{d\triangle}{d\,l} = 2\,K\,l$$

whence integrating

$$\triangle = K\,l^2 \qquad (2)$$

which is the intrinsic equation of the spiral (Williamson, p. 304). It is evident from (2) that the constant of proportionality is the angle hetween the tangent at P. S. and the tangent to the spiral at a unit's distance from P. S. In general we see from (2) that the change in direction effected hy any length of spiral is proportional to the square of the length of the spiral.

5. It is not possible to get the equation of the spiral in rectangular co-ordinates. We may, however, express x and y in terms of $\triangle$ hy certain infinite series. Taking the tangent at P. S. for axis of x and the origin at P. S. we have

$$\frac{d\,x}{d\,l} = \cos\triangle$$

and from equation (2)

$$\frac{d\,l}{d\triangle} = \frac{1}{2\sqrt{K\triangle}}$$

so that

$$\frac{d\,x}{d\,l} = \cos\triangle = \frac{d\,x}{d\triangle}\cdot\frac{d\triangle}{d\,l} = \frac{d\,x}{d\triangle}\,2\sqrt{K\triangle}$$

whence

$$\frac{d\,x}{d\triangle} = \frac{\cos\triangle}{2\sqrt{K\triangle}}$$

or

$$x = \frac{1}{2\sqrt{K}}\int_0^{\triangle}\frac{\cos\triangle\,d\triangle}{\sqrt{\triangle}}$$

Replacing $\triangle$ hy z^2 we get hy easy reduction

$$x = \frac{1}{\sqrt{K}}\int_0^{z^2}\cos z^2\,dz.$$

This quadrature can not he effected in finite terms. It defines a function known as Fresnel's integral, of importance in the theory of light and of importance, also, in the theory of numhers.

The value of y is similarly found to he

$$y = \frac{1}{\sqrt{K}}\int_0^{z^2}\sin z^2\,dz.$$

Expanding cos z in a series and integrating each term separately we ohtain

$$x = \frac{1}{\sqrt{K}}\left(z - \frac{z^5}{5.2!} + \frac{z^9}{9.4!} - \frac{z^{13}}{13.6!} + \cdots\right)$$

or in terms of

$$x = \frac{1}{\sqrt{K}}\left(\triangle^{\frac{1}{2}} - \frac{\triangle^{\frac{5}{2}}}{5.2!} + \frac{\triangle^{\frac{9}{2}}}{9.4!} - \frac{\triangle^{\frac{13}{2}}}{13\,6!} + \cdots\right) \qquad (3)$$

† See Vol. III, series 1, Journal de Physique, 1874.

‡‡ The degree of curve is defined as follows: In an N-degree curve a chord of 100 feet subtends a central angle of N degrees. The radius of an N-degree curve is given by the formula $R = \frac{50}{\sin\frac{1}{2}N^\circ}$. Taking the angle of the sine we see that the radii of the two circles are approximately inversely proportional to their degree of curve.

and similarly

$$y = \frac{1}{\sqrt{K}}\left(\frac{\triangle^{\frac{3}{2}}}{3} - \frac{\triangle^{\frac{7}{2}}}{7.3!} + \frac{\triangle^{\frac{11}{2}}}{11.5!} - \frac{\triangle^{\frac{15}{2}}}{15.7!} + \ldots\right) \quad (4)$$

6. In actual practice $\triangle$ is seldom greater than half a radian or 27°. For values of $\triangle$ of this order we have approximately

$$x = \frac{\triangle^{\frac{1}{2}}}{\sqrt{K}}$$

$$y = \frac{\triangle^{\frac{3}{2}}}{3\sqrt{K}}$$

so that

$$K x^3 \sqrt{K} = 3 y \sqrt{K} \text{ or}$$

$$y = \frac{K}{3} x^3$$

and in actual practice the curve resembles a cubic parabola. A beautiful sketch of the curve is given on page 13 of the Journal de Physique, Vol. III, 1st series.

7. With the same approximation as in the preceding paragraph

$$\frac{y}{x} = \frac{\triangle}{3}$$

Now $\frac{y}{x}$ is the tangent of the angle which the long chord from (xy) makes with the axis of x. For values of this angle which occur in ordinary practice we may call this the angle itself instead of the tangent, and we may employ $\frac{1}{3}\triangle$ as the angle of deflection from P. S. to set the point (x, y).

8. Having selected a value of c, the length of the subchord, K must be determined so as to make the radius of curvature of the spiral equal to 5730 feet at the end of the first subchord (¶3). Expressing all lengths in terms of c, we have at the end of the first chord

$$l = 1$$

$$\rho = \frac{5730}{c}$$

and since by (1) $\rho = \frac{1}{2Kl}$ we have

$$\frac{5730}{c} = \frac{1}{2K}$$

or

$$K = \frac{c}{11{,}460}$$

Now K ¶4 is the change of direction effected by a unit length of the spiral and for field work is more conveniently expressed in angular measure. Therefore

$$K \text{ (in minutes)} = \frac{c}{11{,}460} \cdot \frac{180}{\pi} \cdot 60 = {}^{3}_{10}\, c \text{ (approximately).} \quad (5)$$

Therefore the change in direction effected by the first chord length of the spiral is in minutes approximately equal to three-tenths of the length of the subchord in feet.

9. By using equation (2) this last statement may be generalized as follows: The change of direction effected by n subchords of the spiral is in minutes equal to n^2 times three-tenths of the length of the subchord in feet, or in symbols

$$\triangle_n = {}^{3}_{10}\, c\, n^2. \quad (6)$$

10. Using the result of ¶7, we may state the simple rule for calculating the deflection from P. S. to the end of the nth subchord. The deflection in minutes from the tangent at P. S. to set the end of the nth subchord is n^2 times one-tenth of the length of the subchord in feet, or in symbols

$$d_n = {}^{1}_{10}\, c\, n^2. \quad (7)$$

11. PROBLEM—To compute the deflection from the tangent at any point on the spiral to set any other point.

Taking axes as in ¶5 let the point at which the instrument is set up be (x_n, y_n), and the point to be set (x_m, y_m). If θ be the angle which the chord joining the two points makes with the axis of x, then

$$\tan\theta = \frac{y_m - y_n}{x_m - x_n}$$

and using the approximate values of x and y given in ¶6 and taking θ for $\tan\theta$

$$\theta = \frac{1}{3}\frac{\triangle_m^{\frac{3}{2}} - \triangle_n^{\frac{3}{2}}}{\triangle_m^{\frac{1}{2}} - \triangle_n^{\frac{1}{2}}}$$

or using formula (6) of ¶9, $\triangle_m = {}^{3}_{10}\, c\, m^2$, and $\triangle_n = {}^{3}_{10}\, c\, n^2$

$$\theta = {}^{1}_{10}\, c\,(m^2 + m\,n + n^2).$$

Now the desired deflection is $\theta - \triangle_n$. We have then

$$\theta - \triangle_n = d_{n\,m} = {}^{1}_{10}\, c\,(m^2 + m\,n + n^2) - {}^{3}_{10}\, c\, n^2$$

$$d_{n\,m} = {}^{1}_{10}\, c\,(2\,n + m)\,(m - n). \quad (8)$$

which is therefore the required deflection in minutes from the tangent at the nth chord point to set the mth. The formula serves to run the curve backward or forward from any point and may be used for fractional values of m or n. The approximation is no closer than the formula of ¶6 upon which it is based.

12. The co-ordinates x, y of a point on the spiral may be computed from the infinite series of ¶5. A more convenient method, however, is by latitudes and departures, taking P. S. as the initial point and the tangent at P. S. as the meridian and the subchords as the courses. The angle which any chord makes with the meridian is easily computed from the value of θ given in ¶11, putting $n = m - 1$, to be $\frac{c}{10}(3m^2 - 3m + 1)$. Call this

θ_m. Calculate θ_m from m = 1 up as far as the point x, y, and take out of the tables the sine and cosine of each angle. Then

$$\left.\begin{aligned} x &= c \sum_m \cos \theta_m \\ y &= c \sum_m \sin \theta_m \end{aligned}\right\} \quad (9)$$

As an illustration of the closeness of the approximation in using tbis method we may compute the co-ordinates of the extremity of 200 feet of a 10-foot subchord spiral. The results are x = 197.75 and y = 23.11. By actual calculation, using the series of §5, the co-ordinates are found to be x = 197.58 and y = 23.07. Tables have been computed by Mr. C. L. Crandall giving the values of $\frac{x}{l}$ and $\frac{y}{l}$ for various values of Δ using the series of §5.

13. THEOREM.—The change of direction effected by a spiral of length l isequal to the change of direction effected by a circular arc of length $\frac{l}{2}$ whose radius is the final radius of curvature of the spiral.

Tbe change of direction effected by tbe circle is $\frac{l}{2\rho}$ in circular measure. But since by (1) $\rho = \frac{1}{2\,K\,l}$ this becomes $K\,l^2$ whicb by (2) is equal to Δ.

14. From the theorem of §13 it follows that if a circular arc tangent to the spiral at P. C. and a radius equal to the radius of curvature of the spiral at P. C. be run backward toward P. S. its direction will become parallel to the tangent at P. S. when it reaches a point opposite the mid-point of the spiral. The distance between the tangent to this circular arc at its extremity and the tangent at P. S. is called the shift. Thus, in the figure, the shift is F G.

15. PROBLEM.—To calculate tbe shift.

Let R be radius at P. C. Then in the figure, if S is the shift,

$$\begin{aligned} S &= GF = GK - FK \\ &= y - R \text{ vers } \Delta. \end{aligned} \quad (10)$$

16. The point G in the figure is clearly the P. C. of a circular curve with radius OG = R′ = R + S and center O joining the two tangents T T′. The distance IG is easily seen to be

$$IG = \frac{OG}{\tan \frac{1}{2} I}$$

where I is the angle between T and T′. To calculate the distance from I to P. S. we add to IG the distance G to P. S. which call c. We have

$$c = x - GH = x - R \sin \Delta. \quad (11$$

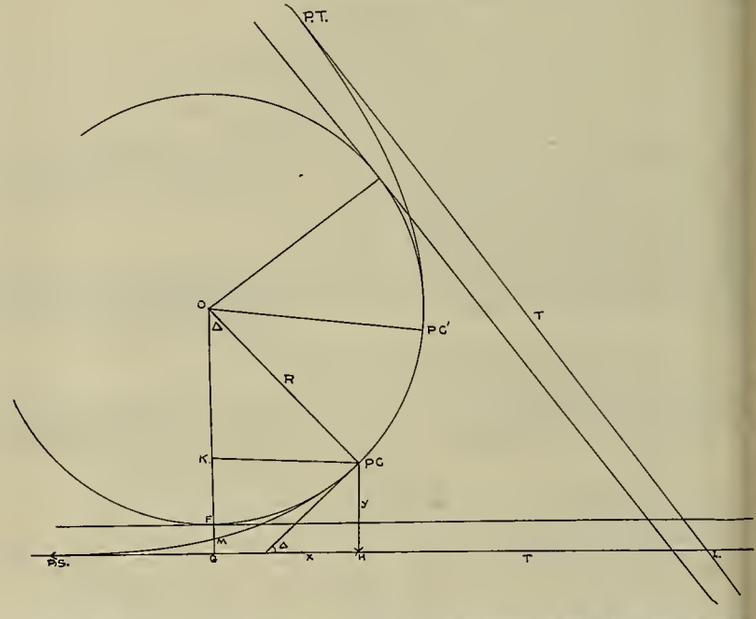
17. All the formulæ employed in calculating the quantities in the tables have now been obtained. The use of the formulæ may be illustrated by computing some of the quantities in table 4, where tbe subchord c is 20 feet.

With transit at tbe eighth subchord, point to calculate the deflections to the other points. Using formula (8) we have, m = 8 and c = 20,

$$d_{n\,m} = \frac{20}{10}(16 + m)(m - 8)$$

or

$$d_{n\,m} = 2(16 + m)(m - 8).$$



Putting m = 0, 1, 2, 3, ... 16, we get the deflections in minutes 256, 238, 216, 190, 160, 126, 88, 46, 0, 50, 104, 162, 224, 290, 360, 434, 512, wbich when reduced to degrees and minutes correspond to the line opposite "Transit at 8th cbord point." These deflections may be calculated easily by tbe method of differences.

To calculate the column headed Δ use formula (6)

$$\Delta_n = \frac{3}{10}\,c\,n^2$$

whicb in this instance becomes

$$\Delta_n = 6\,n^2.$$

Give n the values 1, 2, ... and we get in minutes 6, 24, 54 ....

To calculate the columns headed co-ordinates, we use formulæ (9)

$$\begin{aligned} x &= 20 \sum_m \cos \theta_m \\ y &= 20 \sum_m \sin \theta_m \end{aligned}$$

where $\theta = \frac{c}{10}(3\,m^2 - 3\,m + 1) = 2(3\,m^2 - 3\,m + 1)$. Giving successive values to m we have

$\theta_1 = 2'$	$\cos \theta_1 = 1.00000$	$\sin \theta_1 = .00058$
$\theta_2 = 14'$	$\cos \theta_2 = .99999$	$\sin \theta_2 = .00407$
$\theta_3 = 38'$	$\cos \theta_3 = .99994$	$\sin \theta_3 = 01076$
$\theta_4 = 74'$	$\cos \theta_4 = .99977$	$\sin \theta_4 = .02152$
$\theta_5 = 122'$	$\cos \theta_5 = .99937$	$\sin \theta_5 = .03548$

Adding these cosines and sines, we have successively

$\Sigma \cos \theta_m$	$\Sigma \sin \theta_m$
1.00000	.00058
1.99999	.00465
2.99993	.01541
3.99970	.03693
4.99907	.07241

The values of x and y are then obtained by multiplying these by 20. They are

20	01
40	.09
60	.31
79.99	.74
99.98	1.45

The "long chord" or distance from the point x, y to P. S. is $\sqrt{x^2 + y^2}$
The shift S is given by formula (10)

$$S = y - R \text{ vers } \Delta.$$

Thus for a 5° curve the radius $R = \frac{50}{\sin 2° 30'} = 1146.28$, $\Delta = 2° 30'$ and $y = 1.45$

hence $S = 36.$

The value of c for a 5° curve is calculated by the formula (11)

$$c = x - R \sin \Delta.$$

As before $\Delta = 2° 30'$, $R = 1146.28$ and $x = 99.98$

hence $c = 49.98.$

The values of R′ are calculated from the formula $R' = R + S$.

18. To illustrate the problem most frequently met with, supposed a spiralized 5° curve to be located between two tangents which intersect at an angle of 40° and that the spiral shall have a subchord of 20 feet. Then the spiral at each end will have five such chords and will be 100 feet long. From table 4

$$R' = 1146.64$$

so that the distance P. I. to G is R′ tan 20° = 417.33. To this we add c = 49.98, giving 467.31 as the distance from P. I. to P. S. This locates P. S. Set up the transit at P. S. and run in the spiral by deflections given in the table as 0° 2′, 0° 8′, 0° 18′, 0° 32′, 0° 50′, 1° 12′, 1° 28′, 1° 40′. This last point is P. T. Set up on P. T. and, sighting on P. S′., deflect outward 0° 50′ to throw transit on tangent.

19. If a spiral with 20 feet subchord is to join a 5° 15′ curve and it is desired that the radius of curvature of the spiral at P. C. shall be more nearly equal to the radius of the circular branch than it is at the fifth subchord, proceed as follows:

Make the number of subchords equal to the degree of the circular branch; namely 5¼. Everything is as above except that the co-ordinates of P. C. have to be computed. This is done by adding to the co-ordinates of the fifth chord point the increments due to the subchord of 5 feet. The angle which the fractional chord makes with the x axis computed by the formula for θ given in ¶11. $\theta = \frac{c}{10}(m^2 + m n + n^2)$. Putting m = 5 and n = 5 + ¼ we find $\theta = 2° 35'$. Therefore the increments of x and y due to the ¼ subchord are 5 cos 2° 35′ and 5 sin 2° 35′. S. C. and R are calculated as before.

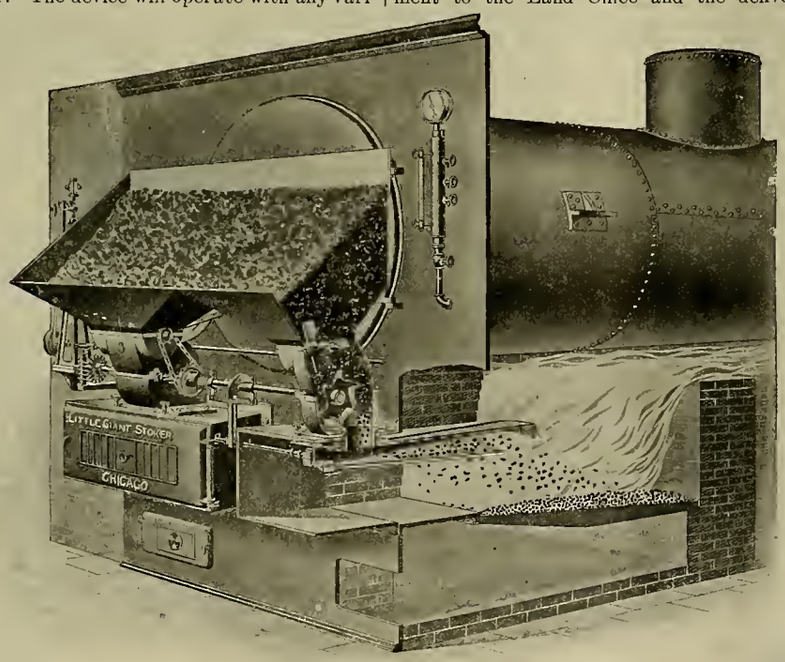
A Mechanical Stoker.

Mechanical firing of coal gives good results as applied to boiler firing. The mechanical stoker illustrated herewith is designed to utilize the slack and cheaper grades of coal ordinarily of so little value to the engineer. The device will operate with any variety of coal, from a size which will conveniently pass through an 1¼-inch screen to the smallest size of slack. The coal, which is first dumped into the hoppers, passes over a revolving cogged wheel, which regulates the flow. It then passes into a slowly oscillating spreader, shown herewith. This spreader moving slowly backwards and forwards distributes the coal evenly, permitting only such a quantity to enter as the conditions may require, and distributing it in such a manner as to cause an even incandescent fire of intense heat.



Mechanical Stoker Designed to Utilize Slack and Cheaper Grades of Coal.

Having but very few wearing parts, all of which are of slow movement and subjected to very little strain, there is practically nothing to wear out. The only part which comes in actual contact with the flames is the spreader, and this can be taken off at will in five or ten minutes. No alteration or damage to boiler front is necessary in attaching the stoker. It is simply bolted on by means of four studs and can be removed if for any reason hand firing should be desired. This device is supplied by Eccles & Smith, 91 Fremont street, San Francisco, Cal.

United States Patents for Mineral Lands.

To the Editor:—I have read in one of your recent issues an interesting piece of information concerning the issuing of patents, to the effect that the assessment work is no more required after the final payment to the Land Office and the delivery of the receipt by said office. This settles a question about which I have heard attorney and surveyor arguing without being able to agree. Now, then, it is manifestly very important for an applicant for a patent to stop as soon as possible the expense of assessment work, mainly when he owns several claims, and it is a fact to be regretted that no one can ever be able to foresee how long it will take before said final payment can be made. The applicant is, of course, willing and able to use all diligence either to survey or correct his survey, but the Surveyor-General's office nearly always requires corrections, technicalities and amended locations, and, unfortunately, informs the applicant of his decision too often only after several months' delay, which results in many hundred dollars of assessment expenses for the applicant, who can not make his final payment before December 31.

There lies all the trouble, and you would render great assistance to the mining interests in bringing the attention of the public to this matter, with the hope that some one competent will see that proper regulations be imposed in the Surveyor-General's office by the Land Office to the effect that a limit of time be given to the Surveyor-General's office in which he should notify the applicant of the corrections deemed necessary. N. E. Imhaus.

Baker City, Or.

The Jackson Electric Drill.

The Jackson electric drill is now being put upon the market by the Jackson Electric Drill & Supply Co. of Denver, Colo., and combines a hammer and piston movement, designed for rapid work, with minimum weight, a big item to mining properties that are compelled to ship machinery long distances by railroad or pack across country. As will be noted by accompanying cut, the motor rheostat and controller is a part of the drill proper, so that when this drill is mounted on tripod or column "it is all there," requiring only a wire stretched from a power plant that may be 50 feet or 5 miles away, or power can be taken from a small $125 gasoline engine or water wheel, should this latter power be convenient.

Jackson Electric Drill.

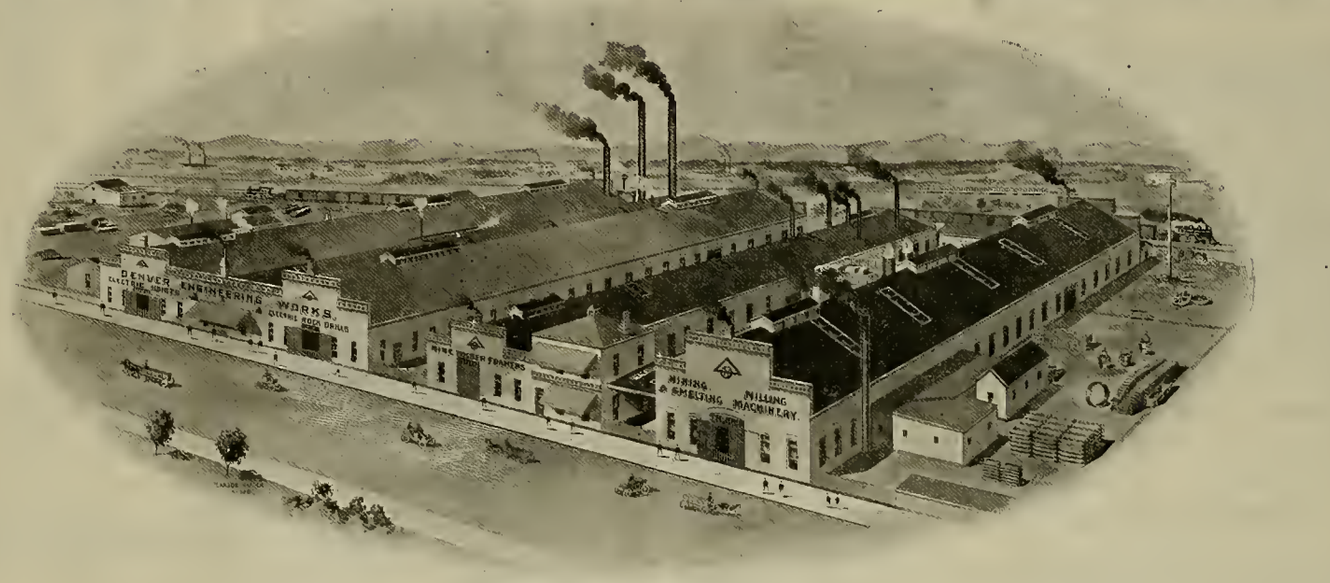
This drill is made in three sizes: No. 1 for stoping or following vein matter, or work not requiring a heavy machine; No. 2 for drifting and tunnel work, upraising, shaft sinking, etc., and No. 3 for heavy tunnel work, crosscutting, and all work in exceptionally hard ground.

The American-Hawaiian line steamer Nebraskan recently made the longest trip ever accomplished with oil fuel. She left San Francisco, Cal., on Jan 23, San Diego on Feb. 3, and passed through the Straits of Magellan to the Atlantic on Feb. 23. Her time from San Francisco to New York, sixty-three days, compares favorably with that of coal steaming vessels. The Alaskan, burning coal, which sailed from New York on Jan. 16, was sixty-three days in reaching San Diego, Cal. The distance from San Diego to New York through the Straits of Magellan is more than 16,000 miles.

The Denver Engineering Works Co.

The Denver Engineering Works Co. operates a plant between 29th and 31st on Blake street, Denver, Colo., with a trackage of two blocks on the U. P. R. R. The tracks enter the shop yard at the rear of the works. The plant was formerly owned by the Overland Machinery Co., who acquired it from the Hendy & Meyer Engineering Co., who started business in 1875.

Messrs. Shepard & Searing acquired the present plant, now known as the Denver Engineering Works, from the Overland Machinery Co. in 1895, since which time many improvements and additions have been made and a large business built up. The plant



The Denver Engineering Works.

now consists of complete patteru shop and foundry, forge and sheet iron shops, machine and erecting shops, all equipped with modern tools and appliances. The shop system is well organized; any piece of work can be duplicated from the records kept by the engineering department, and the accurate cost of any work in the shop, from the time the order is placed on the books, can be determined at any time from the daily records.

The Denver Engineering Works are manufacturers, not solely agents, are equipped to produce the completed machine or plant, from its inception through the various processes of manufacture to its practical operation.

They make their own drawings, patterns and castings, do their own machine and forge work, and finish, erect and test the product of their works. The owners and operators, Messrs. Shepard and Searing, are technically trained and educated men. Mr. Shepard completed his course in engineering at Massachusetts Institute of Technology in 1887, and Mr. Searing at Stevens Institute of Technology in 1888. In 1889 they formed the firm of Shepard & Searing, consulting mechanical and electrical engineers, with offices at Denver, Colorado, and frequently served as experts in legal cases, and in the design and construction of many large plants which are in operation at the present day. As engineers they established a reputation for high grade and honest work, which continued with them and made possible the success of the Denver Engineering Works. On account of the technical knowledge and experience of these men and the fact that they give their persoual attention to detail affairs of the Denver Engineering Works, Mr. Shepard being president and chief engineer, and Mr. Searing vice-president and general manager, the Denver Engineering Works has always occupied a high position among manufacturers of mining machinery.

Improved machines, several designed to cheapen the cost of installation and operation of mining, milling and smelting work, have been originated and put on the market by this company—among these the following: The Box electric drill, requiring only 1½ H. P. to operate; ore crushiug rolls with rigid bearings; the Deuver spitzkasten or ore classifier, built on correct principles derived from extensive experiments by Professor Richards, and made in standard sizes to suit the various conditions; the Cammett concentrating table, to successfully separate mineral from mineral in addition to the concentration of mineral from the waste, designed to make the cost of maintenance less than ¼% of the cost of the table per year; the Denver electric mining hoist, built to meet the severe conditions imposed in mining works; the Deuver mine timber framer, a standard and regularly manufactured machine for framing timbers used in underground mining work, and which does the work of twenty carpenters in one-tenth the time.

Among the numerous customers of the Denver Engineering Works are found some of the largest and wealthiest mining and smelting companies of the world.

On two orders recently placed by the American Smelting & Refining Co., the Denver Engineering Works supplied sixteen of the largest silver-lead furnaces ever built. This company also built for what was formerly the Globe Smelting Co. a lead smelting furnace which is reported to have been the largest ever constructed in the world.

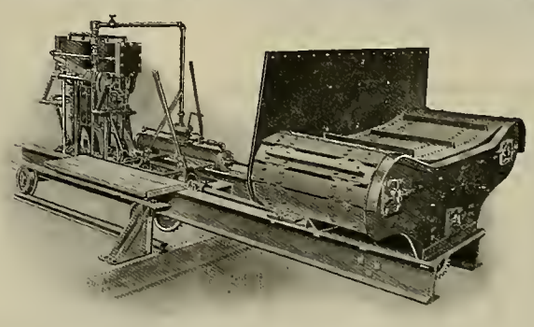
The product of this company's shops is not limited to the immediate vicinity of Colorado, for shipments have been made to almost every mining country on the globe. Their timber framers are in use from British Columbia to South America. One order from South Africa included eight of their sample grinders. One single order from the Colorado Fuel & Iron Co. required 300 tons of castings, all of which were turned out of the Denver Engineering Works' foundry. A recent order from the same company called for a 500 H. P. double drum, double engine, steam mine hoist, probably as large as ever built by any manufacturer in Colorado. A recent order from a Mexican mine called for ten carloads of machinery, and one for Colorado called for twelve carloads. Their stock of gear wheel patterns is probably the largest owned by any manufacturer between Omaha and San Francisco.

They were first in the mining field with their electric mine hoists, which have a national reputation. They build these electric hoists in sizes from 1 H. P. to 2000 H. P.; probably 80% of the electric hoists now operating in the Cripple Creek mining district were built by this company. One mine in Mexico has over forty of this company's hoists in operation.

Modern Mechanical Method of Loading Minerals into Box Cars.

Many railroads have found it advantageous to supply box and stock cars for a large portion of shipments of coal, ore and other minerals, as in doing so this class of cars cau be kept constantly in the earning capacity; and it also insures the delivery of all minerals with quality unimpaired from weather influences and without weight shrinkage in transit.

The loading of minerals into box or stock cars by hand labor has proven to be a slow and expensive method. This difficulty is claimed to have been overcome by a mechanical loader manufactured by the Christy Box Car Loader Co. of Des Moines, Iowa, and illustrated herewith.

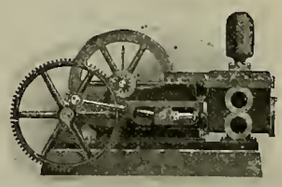


Christy Box Car Loader.

This company on request will furnish a fine catalogue descriptive of their box car loader, showing the manner of operation, with half tone cuts of all parts of both steam and electric loaders, portraying plants having these machines in use, and reproducing testimonial letters from satisfied operators.

Gasolene Pumping Engine.

The Columbus gas engine, as will be noted from cut, is their standard machine, mounted on cast iron sub-base and geared through cast iron cut gears to pumping engine mounted on same sub-base. The crank pin of the pumping engine is carried by a large gear. The frame of the pumping engine is of the girder pattern, the main being very long with an oil reservoir in the center. The cross-head guides are bored, the cross-head being fitted top and bottom with adjustable slippers. The connecting rod is of open-hearth steel forged. The cross-head end is closed with bronze boxes adjusted with wedge and screw. The water end is bolted to the main frame with recess joint to insure alignment. The pump is of the submerged-piston type, piston packed with fibrous packing. The valve seats are of bronze, screwed into decks. The valves are of rubber. All parts of the pump are accessible for attention. The Columbus Machine Co., Columbus, Ohio, also build for mining service hoisting engines aud geared air compressors.



Columbus Gasolene Engine.

Cyaniding Sulphurets Direct.

TO THE EDITOR:—The excellent article by Prof. Christy on "Cyaniding Gold-Bearing Sulphurets" recalls some experiences of my own in that line. The sulphurets in question had been leached for eight days with a 0.25% KCN solution.

Original value of sulphurets	$36.38
Tailings	16.95
Percentage of extraction	53.13

The above values were in gold, no account being taken of silver, as the sulphurets carried but about one ounce per ton.

A sample of the tailings was sized on woven wire screens and assayed separately, with the following results:

	%	Gold Values per Ton.
No. 1—Retained on 60-mesh screen	12.10	$27 70
No. 2—Retained on 80-mesh screen	6.80	25 22
No. 3—Retained on 100-mesh screen	11.69	21 49
No. 4—Passed 100-mesh screen	69.40	12 40

I had no finer screen than a 100-mesh at the plant where this work was done, nor any means of making a water classification, but it is very probable that the portion which would have passed a 150-mesh screen would have shown a very complete extraction.

E. J. BONSTELL.

REGARDING the use of borax in welding steel, an ounce of carbonate of iron to the pound of borax is considered a good addition.

Mining Summary.

SPECIALLY COMPILED AND REPORTED FOR THE MINING AND SCIENTIFIC PRESS.

ALASKA.

A report from Fairhanks says another hig strike has heen made on a new creek 4 miles from Chena, called Cripplo creok. It is midway hetween Chena and Fairhanks and has hoen passed over by almost everyhody traveling hetween these two points. Recently prospectors put down holes on what is now discovery. They got good pay, hut kept tho matter quiet; hut others prospected their dumps and fouud things so satisfactory they started a stampede. Sinco then the discoverers have allowed men to pan in their holes, and roports coming from there are to the effect that the ground averages 15 cents to tho pan.

It is reported that letters from Tanana, the newly discovered placer region, state that the clean up of the past winter's work will approximato $1,000,000. Numerous new discoverics aro reported.

Reports from Bullion creek continue to come in, says the Skagway Alaskan. It is stated by those returning from the diggings that everywhero hedrock has heen struck the pay runs from 50 cents to the pan upward. F. Attermost and F. Ater say that they struck hedrock on one o their claims at a depth of 44 feet and found an average of 52 cents to the pan. The hedrock was covered with a sediment 2 feet deep which avoraged 3 cents a pan. T. Flaherty says that of every claim being worked or prospected the same story is told. Those on the trail are having no difficulty in getting their outfits over the trail. Bullion creek claims are selling at Whitehorse. No. 147 above discovery is reported sold for $1000. Ruby creek is deeper than Bullion creek, hut the henches, which are shallow, have heen discovered to he rich.

ARIZONA.

Maricopa County.

(Special Correspondence). — A Lane roller mill and other machinery is to be installed at the Relief mine, near Peoria, at an early date.

J. Creath has completed a cyanide plant near the arrastra on the Broadway ditch. He will soon be ready to cyanide the tailings from the arrastra.

The Ben Hur mine, a gold property near the Phœnix mine, in Cave Creek district, is working.

J. G. Hardin has sold a number of claims near the Union mine, 18 miles north of Phœnix.

Cave Creek, April 11.

(Special Correspondence).—Some fine specimens of muscovite (mica) have recently been obtained from the Santa Estrella mountains, southwest of Phœnix. Preparations are being made to do work on the claims. The mica is found in large plates, which are seldom clouded.

The Michigan Gold Co., who have been operating dry placer machines near Morristown, have shipped the concentrators to Congress Junction, whence they will be freighted to Plomosa district, in the Quartzite country. They will install a plant having a capacity of 15 tons of gravel per hour.

C. E. Philes is developing a gold property in Cave Creek district.

The Wickenburg smelter will be blown in within the next few days, awaiting the arrival of coke. Considerable ore is at the smelter.

B. Carr, B. Cosner and W. Dennison have started work on a claim they recently located south of Phœnix. The ore is free milling and carries about two ounces of gold per ton.

The Pike's Peak M. Co., operating property 8 miles west of Frog Tanks, have an incline down 269 feet, and sinking continues. A large vein of sulpbides, carrying gold values, has been cut. A 40 H. P. steam hoist is in use.

J. Anderson and H. H. Gillespie are in the McDowell mountains doing assessment work on their property.

Ohio men have recently bought an interest in E. Howard's gold property, northeast of Cave Creek, and work will be started. The shaft will be cleaned out and retimbered, and sinking resumed. The ore is free milling.

The Gila Monster mine, near the Union mine, in the Union district, has been surveyed for patent.

Phœnix, April 11.

(Special Correspondence).—Des Moines, Iowa, men contemplate the purchase of the Roberts group of claims in the White tank mountains north of Buckeye.

R. F. Doll and J. Sthrole are developing their gold property in Cave Creek district, it is reported, with good results.

J. Johnson has recently located a claim north of Phœnix, in the Union district. The ore assays in copper, silver and gold.

I. Moore and C. Warner of Glendale havo left Phœnix for the Eagle Tail and Harqua Hala mountains, where they will prospect. Somo weeks ago they discovered good copper and lead ore in tho Eaglo Tails.

Phœnix, April 10.

(Special Correspondence).—G. E. Sanders has sold to the Vulture Dev. Co. the St. Charles group of claims in Vulture district.

F. E. Withey is working men on tho Grand Traverse mine, north and east of Cave Creck. He also has a numhor of men doing assessments on other claims.

Wickenburg, April 12.

Mohave County.

(Special Correspondence).—F. W. Theis has struck shipping ore in his Apex shaft, near Chloride. The owner will remove the steam hoist from the Silver Age mine and continue sinking to 200 feet.

Drifting and stoping on the Treasuro Vault mine is progressing. The ore mills $80 in gold and silver.

Another shipment of ore from the Fourth of March mine leaves for tho smelter next week.

The drift on the 240 level of the Sunrise mino is in good ore.

The Buckeye mine, at Mineral Park, where work was recently resumed under lease, has cut the vein in the 350-foot tunnel. Three shifts are heing put on.

The Sun Cloud mine on Burro creek, south of Kingman, has received all the machinery for the 100-ton mill. The mine has a large tonnage of ore hlocked out.

The Standard mine, in Chimehuevis district, is outputting high-grade gold ore. This and other claims in that camp helong to the Standard G. M. Co. They are contemplating reduction works.

The Cedar Valley M. Co., at Cedar, has struck high-grade ore.

G. Goetz has found a vein of gold ore, 4 feet wide, in Cedar district.

The Samoa mine is sacking ore for shipment.

The Altata mine is in a 15-inch vein of horn silver ore.

The Brunswick mine, belonging to Hughes & Mitchell, has a 10-inch vein of high-grade gold ore.

A good flow of water has heen struck in the Manzanita mine, which will he used in the Minnesota mill. The vein is small, containing gold and copper.

The Buckeye mine at Mineral Park, recently leased by M. Neilson & Co. of Wickenburg, is in good ore.

The Gem mine at Cerhat is heing developed under contract.

H. T. Blackwell has struck a vein of sulphide ore in his Dufferin mine.

It is reported the Tennessee mine and mill are to resume work. The mine has 8 feet of milling ore on the 500 level.

G. F. Milliken of New York has a bond on the Gem mine at Cerbat and is now there unwatering the mine.

The J. Carter lease on the Gold Road mine at Acme is outputting $300 gold ore.

The double-department shaft on the De La Fountaine mine at Stockton hill is down 350 feet in good ore.

It is reported that A. J. Pickerel of Prescott, manager of a gold mine 4 miles west of Kingman, visited the property this week with the intention of starting up and later installing a milling plant.

Chloride, April 10.

The new hoisting plant on the Yavapai mine in Clifton district is completed and in operation.——The new addition to the Shannon Co.'s concentrator is in operation.

Development on the Lezinsky property, near Clifton, is progressing. The vein in the Copper Bluff tunnel has heen opened to a width of 75 feet.

A strike of a 2-foot vein of red oxide ore, averaging 40% copper, is reported on the property of W. Keathing, near Morenci.

Pinal County.

(Special Correspondence).—Men are at work at Superior, near the Silver King mine.——G. A. Howell is working on a promising gold property, east of the Buttes and north of the Gila river.

Mammoth, April 9.

(Special Correspondence).—The Pinal Paraffine Oil Co., who are drilling in the Hackherry wash near Kelvin, have their well down to a depth of 1608 feet and indications for oil are very good. It is now necessary to put in more casing before drilling can be resumed.

Kelvin, April 12.

Yavapai County.

(Special Correspondence).—H. Herford of London, representing an Englisb syndicate, has interested his company in the Cleopatra and Con. King and Columbia properties, near Jerome. A smelter will he huilt. The properties surround the United Verde and lie between it and the North and South Venture claims, which are detached and lie to the south of the smelter site, across Walnut creek. The new company proposes to install their smelter on Walnut creek. A tunnel 1400 feet long is projected into Jerome mountain, which will give them the depth of the 500-foot level in the Jerome mine, and from this crosscutting and raising will open up the property. G. W. Howe, from whom the property was hought, retains an interest and will remain in charge at Jerome.

In and about Jeromo considerable interest centers just now in the new smelter which was hlown in last week at the Equator mine, 8 miles south of Jerome. This mine is the old Iron King property, which, after years of litigation, was divided hy compromises, one part going to the Clark interests and named the Equator, the other to Eastern parties and called the Copper Chief. The latter has been developed, and it is stated hy the agent, A. Hendey, that there is in sight a large amount of oxidized ore. The company has installed a leaching process which had heen previously tested in the laboratory and found successful. A 100-ton plant was so arranged that it could he added to, and the process, it is said, extracts 98% of the values. Work was discontinued, but the plant is in good order and work may be resumed on this property at any time. The Equator has heen developed by tunnel and upraise and bodies of ore are opened up sufficient, it is said, to justify a smelter, which had its initial run last week. (The engravings on page 263 illustrate the plant.) To connect mine and smelter a section of bucket tram was utilized that before the construction of the railroad into Jerome had heen used to convey supplies from the top of the mountain to Jerome smelter. The section in use at the Equator is ¾ of a mile long. It is a continuous cahle, carrying 100 huckets, each with a capacity of 400 to 600 pounds, and a complete revolution made once an hour. The weight of the loaded huckets generates considerable power, one of the greatest difficulties heing the control of the cahle. The recent storm necessitated a shut down, as the wet cable slipped in the cushion wheel, causing a runaway. J. A. Grace is in charge of the smelter. The matte is hauled to Jerome and all supplies are brought in by wagon, a distance of 11 miles hy the road. J. F. Case, foreman of the mine, is a recent arrival from Butte, Mont. The mine force consists of fifty men, and stoping is in progress.

Jerome, April 12.

(Special Correspondence).—The Rigby M. & R. Co.'s plant at Mayer, now being erected, is intended to treat all classes of ore by the Pohle-Croasdale process, owned hy The Metal Volatilization Co. (The engraving on the front page shows the plant and surroundings.)

The ore is delivered to the Mayer plant hy the Santa Fe, Prescott & Phœnix Railway Co. over a spur 3000 feet long from their main track to the Rigby Co.'s works, weighed and dropped onto the unloading track in front of the sampler, where it is shoveled into the ore chute feeding the crusher sampler, this being the only time the ore is handled by shovels. The sampler building is 38x36 feet, the ore from the cars going to a 20x10-inch Blake crusher, thence to an elevator, which delivers it to a ¾-mesh screen, the finished product going to a double Vezin automatic sampling machine, oversize returning to 36x14-inch rolls, which discharge into the same elevator as the crusher. The sample from the sampler goes to the sample bin on the cutting floor, where it follows the usual custom in making a sample for control and umpire assays. The reject from the sampler is taken by a 16-inch belt conveyor and dumped into one of the ore bins adjoining the west end of the sampler building, which have a capacity of 750 tons. From them the ore is drawn into cars and taken to the dryer huilding, 56x30 feet, where it is fed by automatic feeders into two revolving dryers. From the dryers the ore is dumped through a brick chute into a car and taken to the fine crushing building, 56x30 feet, where it is crushed to the required fineness by three pairs of 30x14-inch rolls, the finished product heing taken from the screens to the pulp ore bin by a 16-inch belt conveyor. In this huilding the salt used in the process is crushed by a pair of 20x12-inch rolls to the same fineness as the ore and is taken by car to the salt bin, adjacent to the pulp ore bin. Besides the rolls, screens, elevators and conveyors in this huilding, there are three dust collectors and fans and four feed hoppers, with feed screws, feeding elevators and rolls.

The ore and salt from the fine crushing building goes to the pulp ore and salt bins in the mixer building, through the conveyor building, 28x8 feet. The mixer huilding, west of the fine crushing building, is 64x14 feet. There is a hopper scale under the pulp ore bin, another under the salt bin, from which charges are run onto a 16-inch helt conveyor, which carries them to the receiving hopper over the mixer, and from which it is discharged into a 5-ton hox mixer, when after mixing it is dumped into a storage hopper under the mixer, from which it is drawn as needed into a car and taken to the furnace feed hoppers, through a tram house, 100x8 feet, one story high.

The furnace building is 132x88 feet. In it are four revolving, hrick-lined furnaces, 7 feet 6 inches at the large end, 5 feet 6 inches at the small end, and 36 feet long. From the feed hopper of the furnace the ore is fed into the furnace by a screw feed, the roasting process being continuous, similar to the operation of a White-Howell furnace. The tailings from the furnaces are automatically conveyed to cars by a hot ore conveyor and taken to the dump in them. The fuel used is California crude oil. The ore having heen mixed with the proper amount of salt and sulphur before going to the furnace, the mixture permits of a double decomposition, by which the metal values are converted into chlorides, volatile at the roasting heat, and the sulphur into sulphate of soda. The chlorine fumes are drawn from the furnaces hy lead-lined pressure blowers, through a series of chambers and flues into the flue house, a building 100x31 feet 6 inches, from there into the condenser building, 96x44 feet, passing through a cooling tower which contains gravel filters kept wet hy constant sprays of water. This cools the fumes passing into the pressure blowers and the linings are not injured hy heat. From the hlowers the fumes are forced into condensers and through the diaphragms and water contained in them, until the values are removed from the fumes.

The solution thus formed is conveyed to the filter house, 56x30 feet, through lead-lined launders. The gold and silver present in the liquid are in insoluble form. The lead, when present, is recovered in the form of sulphate, by reason of the acid solution, and is insoluble, so that all three of these metals are easily removed from the solution hy filters. The copper, heing in solutiou, passes through the filters to the precipitation house, where it is precipitated on iron or hy electricity. The precipitation house is 42x55 feet. The power is steam. The hoiler house is 56x30 feet and contains three 125 H. P. hoilers, together with hot water heater, boiler-feed pump and injector. The fuel used is California crude oil.

The power is applied hy two 14x36-inch and one 12x30-inch Reynolds-Corliss engines, located in two engine houses. In one house, 64x29 feet, are placed the two 14x36-inch engines, one driving the machinery in the mixer, condenser and furnace houses, the other driving the machinery in the dryer and fine crushing houses. The 12x30-inch engine is placed in a house 34x20 feet and drives the sampler house machinery.

In addition to the huildings which are directly connected with the working of the plant are the following: Brick office, 41x31 feet 6 inches; brick laboratory and assay office, 49x17 feet 6 inches; carpenter and machine shop, 60x20 feet; hlacksmith shop, 30x20 feet; warehouse, 40x20 feet; oil house, 16x12 feet; wooden dwelling house, 112x14 feet, with three wings. All buildings are wood frames covered with corrugated iron, unless otherwise described. An oil reservoir, excavated in solid rock and cemented, 55x22 feet and 9 feet deep, holding 75,000 gallons of crude oil, furnishes the fuel for the plant, and is distrihuted through the various buildings by a gravity system of steam-heated pipes.

The plant is designed to have a capacity of 100 tons of ore per day and will be in operation in June.

Mayer, April 11.

(Special Correspondence). — The Braganza G. M. Co., locally known as the Henrietta, is located at Big Bug, on the Poland branch of the Bradshaw Mountain Railroad. The 20-stamp mill stands near the railroad, and ore is conveyed to it from the mine on the hill above by cable tram. The Henrietta is on the same belt with the McCabe, Gladstone, Jessie and Dividend and has a long record of production. At present the twenty stamps crush only thirty tons per day, but Superintendent J. D. McLaughlin hopes to replace the mill with a new one during the season. There are six claims in the group. At the 300 level a tunnel 1500 feet long cuts the hill from north to south. On the south side of the hill sulphide ore was found from the surface with an average value of $15 per ton. On the north side the ore was oxidized down to the 400-foot level. There is a total of 1100 feet of timbered shaft on the property. The labor trouble last season closed this property, but since Septemher last it has again been operating with a force of sixty men. E. E. McNasser has charge of the mill, amalgamation and concentration being em-

ployed, sending from two to three carloads of concentrates, averaging $40 per ton, to Val Verde smelter each month.

The Alto M. Co. has seventeen claims in Eugene gulch, 2 miles northwest of the Henrietta. A. J. Frame of Athens, Ohio, is president and S. I. Johnson superintendent. A road has been completed to the Paymaster group, on which a 400-foot tunnel has opened up a vein of sulphide ore carrying gold values running from $8 to $171. A raise from this tunnel, 100 feet to the surface, has been completed and a hoist is being installed and a shaft will be sunk from the tunnel level. The principal work has been done on the Jefferson group, where the working shaft has now reached a depth requiring a larger hoist, which will soon be installed. The ore will be sent either to the new Rigby chlorination plant at Mayer or to the Val Verde smelter, equidistant, 6 miles away, until development has been carried far enough to determine the process to treat the ore.

Providence camp, in Big Bug gulch, 3 miles east of Poland, is lifeless at present. The Belcher property is idle, as also the Stirling and Merchants. The Annie and Red Rock mills are silent. From the Lottie tunnel, now in 3700 feet, on Wood gulch, flows 175,000 gallons of water per day. The owners—the Oriental M. Co.—are operating their mill near Poland with ore from the Paymaster mine, the only mill operating in the district at present. The mill is in charge of B. F. Thomas. Lately plates have been added with good results, saving the fine gold that has lately appeared in the ore. The mill is running smoothly and saving, it is claimed, 90% of the values. The ore is hauled from the mine, 1 mile away, over a good road at a cost of about 27 cents per ton. It is sulphide, carrying gold and silver, with some lead, zinc and copper. Concentrates are being shipped to El Paso, Texas. The company contemplate building a mill in Wood gulch of 100 to 200 tons capacity to handle ore from the Lottie mine. The Oriental is a close corporation; A. F. Kent, Jamestown, N. Y., is president and W. A. Kent superintendent of mine and mill. Since the strike, last June, but twenty men are employed.

Big Bug, April 10.

(Special Correspondence).—The Knickerbocker G. M. Co., locally called the Hidden Treasure, started its 10-stamp mill a few weeks ago, employing amalgamation and cyaniding, with encouraging results. The mine is operated through a 200-foot shaft, having 800 feet of drifting on the two levels. The property is on Turkey creek, 4 miles southeast of the station of that name on the Bradshaw Mountain Railroad.——Thiesing & Riley are developing copper property near this mine.——Assessment work is now being done on the Silver Cord, owned by C. E. Mills, J. A. Robeson, J. R. Lowry and G. Zika. There is a 280-foot tunnel on the property and some rich ore has been struck.

Turkey Creek, April 10.

(Special Correspondence).—J. B. Richman, one of the owners of the Alaska mine, near Congress, says a gasoline hoist will be installed at once.

Congress, April 10.

(Special Correspondence). — Nineteen miles northwest of Hillside station is the Golden Link mine and mill. Hillside is 20 miles north of Congress junction, on the S. F., P. & P. R. R. A trial run of the 20-stamp mill was made last season, but work was discontinued while changes were made, and it was not until February of this year that regular work began. The mill has a capacity of sixty tons per day. About 60% of the values are plated, the remainder being extracted by cyaniding. From mine to tailings every step is by gravity. Oil is used for fuel, hauled from Hillside by teams, 1000 gallons a day being required for the plant. Water is pumped from the Santa Maria river, 1 mile away, to an elevation of 500 feet by a pump operated by electricity, which also furnishes light for the mill. A compressor plant supplies air for agitation in cyaniding purposes. There are five leaching vats, each seventy tons capacity.

The mine is worked by tunnels, which enter the hill above the level of the mill. The ore is siliceous, in granite, and while little free gold can be seen, it yields readily to the treatment. Fifty men are employed. H. R. Johnson of New York, at present at Pasadena, Cal., is president of the company, and H. L. Montagne is general manager.

John Roberts of Sultan, who, with others, owns copper prospects on Copper creek, 19 miles north of Sultan, is negotiating the sale of the property. It is 3 miles from the Hillside mine, which with its 5-stamp mill is now in operation under direction of John Lawler of Prescott, the owner.

Hillside, April 11.

(Special Correspondence).—On the Agua Fria, 5 miles east of Mayer, are the properties of T. T. Stoddard (the Copper Mountain), J. Mayer (the Miner) and the Lion Copper M. Co. of Los Angeles, Cal. The ore of this section is principally copper bearing. On the first-named property a great deal of development work has been done, and a smelter, now idle, formerly reduced the ore. H. E. Schaefer is in charge of the property.

The Lion has a shaft down 250 feet and is working nine men in two shifts, sinking. The work is in charge of H. Reifsnyder. C. Matthews of Los Angeles, Cal., is president of the company.

Mr. Mayer has a force of men under Frank Thornton on his property, the Miner, and the showing of ore in shaft and tunnel, as far as developed, is encouraging. Considerable high-grade carbonate ore is piled on the dump and the shaft is coming into a body of sulphide ore.

Mayer, April 11.

(Special Correspondence). — The Dividend Con. G. M. Co. is a consolidation of four adjoining groups of claims, the Dividend, Galena, Independence and Comstock, comprising eleven full claims. T. G. Smith of Los Angeles, Cal., and an owner, is at the mine. F. E. Byles is general manager of the company and Kelvin Hartwell of Los Angeles, Cal., is president. The mill has ten stamps, with a capacity of twenty tons, having two Bartlett and one Wilfley table. Concentrates are shipped to Val Verde smelter. Water for operation is pumped from the mine.

There is a shaft on each of the four groups, the deepest being 400 feet, and about 4000 feet of drifting has been done. Little stoping has been done. A new hoist has been installed on the Dividend and a new 75 H. P. engine and 80 H. P. boiler installed in the mill.

All development that has heretofore been done has been paid for by the ore mined. A 1200-foot gravity tram is being installed to connect the Dividend shaft with the mill, which is located at Chaparral postoffice, ½ mile south of the Jessie mill.

Chaparral, April 11.

(Special Correspondence). — North of Blanchard the Douglas-Lacy Co. is operating an extension of the Iron King ledge. They have sunk four shafts through the wash gravel, varying from 80 feet to 252 feet, and have located the ledge at two points. The second shaft is now down 284 feet. Some good carbonate copper ore has been taken out.

Val Verde, April 11.

(Special Correspondence).—The Jessie and surrounding claims, about 1 mile south of McCabe, was located in 1890. Rich surface ores were found and the initial 5-stamp mill was increased to twenty stamps, with concentration and cyaniding plant. The mill was located ½ mile west of the mine, near water, and a tunnel driven 1333 feet, crosscutting several ledges. For thirteen years work has been carried on in the surface levels.

The property is owned by the Jessie Mines Co. of Columbus, O.

A new system of development is now being inaugurated. The water question has been settled by the company acquiring the De Large ranch, on the Agua Fria river, where a 500 H. P. electric plant will be installed as a power and pumping plant. From this a pipe line will conduct water to a point 4½ miles from the pump, at an elevation of 1100 feet, and from here it will flow by gravity 2 miles to a tunnel reservoir above the Jessie. This reservoir is now being made by drifting on a vein which furnishes ore enough to pay cost of construction. It will be cement lined and will hold 1,000,000 gallons. Its location furnishes a good head of water as fire protection.

A large shaft house has been constructed over the old Jessie shaft, down 657 feet, double compartment. It is being retimbered and straightened to a uniform incline of 75°. The shaft followed the vein. Now, in straightening it, lenses of high-grade ore are found lying contiguous to the main vein. Below the shaft will be built a 60-stamp mill, with concentrating and cyaniding plant, which it is expected will be in operation this year.

On the dump is about 40,000 tons of ore, stated by Mr. Jones to have an average value of $8.35. The main ledge is 100 feet wide, the paystreak from a few inches to 12 feet. On the walls of this vein, and also in seams through it, are streaks of ore from 6 inches to 3 feet in width, running in value from $250 to $300 gold. The main ore body, second grade, runs $12 to $16. The high-grade ore is pyritic. The new shaft will be sunk to the 1000-foot level. At present thirty men are on the payroll.

The old Jessie mill is on another part of the property not included in the present company's holdings, but will be operated under another company, Jones Bros. being the present owners.

The southern extension of the McCabe vein is owned by the Ideal M. & D. Co., locally known as the Gladstone Co. It is worked at present under lease by C. G. Fennell and J. L. Davis, who are taking out high-grade galena ore. They also have the Val Verde smelter, to which the ore is shipped. The mine lease expires Jan. 1, 1905, and the smelter will be turned over to the Middleton Co. within a few days. L. Martin, resident at the mine, looks after the interest of the owners.

Between the Jessie Mines Co. and the Dividend Con. G. M. Co. is the Lelan group of eight claims, of which E. W. Wells of Prescott is president and Elmer W. Wells is general manager. Development is in progress, a contract having been let to sink the shaft from the fourth to the fifth level. The company is negotiating for a mill, which will be commenced when sufficient water is encountered in the mine to operate. M. B. Hazeltine of Prescott is treasurer of the company.

McCabe, April 12.

CALIFORNIA.

Amador County.

The first cleanup of the new 20-stamp mill at the Bunker Hill Con. mine, near Amador City, was made last week, says the Amador Ledger. Owing to an accident to the rock breaker, only ten stamps were run part of the month. The month's run averaged, it is reported, $6 per ton. The ore came mostly from the 1200-foot level, which is stated to be poorer than the ledge in the 800 and 1400 levels.

The underground men at the Zolla mine at Jackson have been laid off because of the large volume of water in the works, requiring constant running of the water tanks.

Butte County.

Two hundred acres of land, located 2 miles south of Oroville and 1 mile from Feather river, are reported sold to the Vilora Mining Syndicate, Ltd., of England. The price paid was $800 per acre.

Calaveras County.

(Special Correspondence).—A rich strike is reported on the 1900 level of the Gwin mine, where a shoot of ore, presumed to be the downward continuation of a shoot found in the upper levels, has been cut. The drift is in on the lens about 40 feet, the vein having widended from a thin edge to over 3 feet. The rock mills $40 per ton and resembles the rich ore found above, on the 1200 and other levels.

Gwin Mine, April 12.

Ore from the Merrimac claim, on lower Carson creek, is being milled in the mill of the Carson Creek M. Co. The ore consists of schist with stringers of quartz, carrying free gold and auriferous iron sulphides.

El Dorado County.

Superintendent W. E. Everson of the El Dorado C. Co. reports finding the ledge in the Ford copper mine, east of Georgetown. They have 8 inches of solid mineral. The tunnel is in 203 feet.

At the Mameluke hill hydraulic mine, operated by the New Highland G. & C. M. Co., new sluice boxes are being put in under Foreman Biddell. It is thought sluicing will commence by May 1st.

Mariposa County.

(Special Correspondence)—The Raynor Copper M. Co., operating mines 4 miles south of Lewis, made the second carload shipment to Selby's last week, the first shipment being made two months ago, and averaged 21% in copper and two ounces in silver per ton. J. C. Jens is general manager and L. J. Beeve foreman. The company has a new hoist on one of their shafts and is down about 200 feet.

Mariposa, April 11.

A number of new locations have been recently made in the Quartzburg district, near Hornitos. The Washington mine is the most extensively developed property in the district. It is 1500 feet deep, but has been idle for years.

Mono County.

The North Rapidan mine at Como is being prepared for development work. The mill is to be started early in April, says the Bodie Miner.

Manager W. A. R. Loose of the Sunshine Co. has laid off the men, except those on the Sunshine claim. He has located six claims for the New Bodie M. Co. A tunnel will be run which will tap and drain the mines at a depth of 1500 feet. The tunnel will be 3 miles long when completed.

There is a report at Benton that the old Tower mine at that place is to resume operations.

Napa County.

(Special Correspondence.). — Recently the miners at the Boston quicksilver mine struck for an advance in wages. General Superintendent B. M. Newcomb ordered the furnace fires drawn and all work suspended indefinitely. Fully 100 men are affected by the shut-down.

Oat Hill, April 12.

Nevada County.

(Special Correspondence).—The Oustamah mine is regularly shipping concentrates to the Pioneer Works. They are hoisting thirty tons of quartz and thirty tons of waste per day, mostly from the 300 and 500 foot levels. It will be remembered that this mine was abandoned as being worked out after sinking 800 feet and taking out all the ore south of the shaft. The main ore body was lost north of the shaft, the miners having followed the foot wall. The new company followed the banging wall and found the ore body at the 500-foot level. Subsequently it has been found at the other levels and promises well for the future. At present they are in 600 feet and stoping on the 300-foot level 800 feet, and two stopes on the 500-foot level, 450 feet in the 600 and 275 feet in the 700. Below the 700-foot level the shaft is filled with water. The company intends pumping and cleaning this out, sinking farther as is necessary and drifting both north and south below the 800-foot level, as the south was worked out by the old company above this. The vein formation in this mine is looked upon as a fine exemplification of Janin's "rhomboidal theory." Mr. Morgan is superintendent.

Nevada City, April 9.

(Special Correspondence).—The Empire mine, G. W. Starr, superintendent, is hoisting 100 tons of quartz and 100 tons of waste per day, about half the capacity of the plant. The hydraulic pump at the 1100-foot level is handling all water brought to this level from the 2200-foot level and raising it to the 400-foot level. This pump is operated by water falling 930 feet vertically from the surface and entering the power cylinder of the pump. The piston in this cylinder operates the suction and pressure valves, forcing the exhaust power water as well as the mine water to the drainage tunnel at the 400-foot level. The Word drill sharpener lately taken on thirty days' trial has proved satisfactory and has been purchased.

Grass Valley, April 10.

(Special Correspondence).—The experimental 10-ton cyanide plant at the North Star mine has been in operation over a week and so far has proved satisfactory. The pulp from the plates is run over Dodd buddles, thence the tailings are run into a settling tank or spitzkasten. The slimes and sands are allowed to settle to the bottom and the clear water flows gently over the circumference. Lime is added to hasten settling. An air pump forces the sands and slimes from the settling tank to the solution and precipitation tank. The cyanide solution, pumped from the sump tanks and made of proper strength, is added to the pulp. A continuous circulation and agitation is produced by forcing air through a pipe up the middle of the tank, carrying the solution with it. The solution goes up the center and comes down the sides. In the bottom of the tank a series of amalgamated copper and iron plates is arranged concentrically about the center and connected to a plating dynamo of one and one-half volts and fifteen amperes. This deposits the gold from the cyanide solution upon the amalgamated copper plates, which are subsequently treated as are battery plates to recover the gold.

Experiments show that this method gives 90% to 95% extraction with the fine slimes, which carry three-quarters of the assay value of the tailings and 70% extraction with the coarse sands. The tailings run about $2 per ton, and the estimated cost of treatment by this method is 50 cents.

If the experimental plant proves successful the North Star Co. will put in a complete plant for treating the entire product of their 40-stamp mill and also the new mill being erected at the Central.

Grass Valley, April 12.

Manager Campbell, for the Mountaineer G. M. Co., has bought the Reward mine, near Nevada City, from the Gold Tunnel Co. This mine is between the Walrath and Summit mines, which the Mountaineer Co. also has. This, with a tunnel right through the Weisenburger ranch, which was recently obtained, gives them a continuous right from the Mountaineer mine on the north to the East Orleans mine on Gold Flat, a distance of 3½ miles. Manager Campbell is driving ahead the tunnel which starts from the 400-foot level of the Mountaineer mine. In the meantime the work of reopening the Mountaineer proper is progressing.

The Continental C. & G. M. Co. has been organized to operate gold and copper properties in Nevada county. The company has a bond on the Badger claim at Pike Flat, in addition to a number of copper claims near Newtown. U. P. Koenig of Milwaukee, Wis., is president, with

T. C. Robinson, F. H. Kline, S. M. Harris, L. C. Wilhelm and W. George directors. The shaft of the Badger will be cleaned out and retimbered, after which sinking will start. It is intended to go down 500 feet. The company will put in a hoist and pumping plant. At same time it will open up its copper properties west of Nevada City. It has five claims, in addition to the Williams ranch of 240 acres, in the copper belt running through to Spencoville. A 50-foot shaft has been sunk on one of the claims, being in gossan. Assays are said to show gold and silver values with the copper.

O. Woehler, general manager of the South Yuba M. & S. Co., near French Corral, says No. 6 tunnel shows great improvement. The tunnel is in 275 feet. The vein is from 25 to 50 feet wide.

During the heavy rains the management of the Centennial and Green Mountain mines, in Grass Valley district, decided it would be more economical to allow the mines to fill with water, pumping them out later, than to keep the pumps going all the time, says the Nevada Minor. Now that the water has subsided somewhat the management has decided to install heavier pumping machinery, and will move the compressor from the Centennial mine to the Green Mountain, where it will be used to drain both mines of water. These mines have been consolidated as the Sultana mines. J. M. O'Brien of San Francisco is looking after the property. Another motor will be bought that the hoisting machinery may be capable of working to greater depth. Both mines will be worked from the Green Mountain shaft.

A new canvas plant is being built at the Oustomah mine, near Nevada City.——A vein of gold-bearing quartz was discovered while excavating for a building in Nevada City a few days since. It is thought to be an extension of the Nevada County vein.

Plumas County.

The main tunnel of the Clay bank mine, near La Porte, is again being driven. A raise to connect with the channel which was being put up was abandoned recently, owing to the downpour of water.

The Wild Boar mine, near La Porte, is temporarily idle, owing to scarcity of fuel.

Riverside County.

The Oro Copia M. & M. Co. are sinking a well near Dos Palmos station in the Salton basin, to supply water to their mines, 10 miles to the northward, in Quartz Peak canyon. A mill has been taken to the mine.

Sierra County.

A rich strike is reported at the Mabel Mertz mine, says the Downieville Messenger. The company were running a bedrock tunnel for gravel when they found a quartz ledge 10 feet wide. A good prospect has been obtained from the ledge, which is in porphyry and slate, and free gold can be seen in the rock. The mine is owned by the Forest City M. Co. and is 8 miles from Downieville. Good prospects in gravel were obtained at this mine some time ago.

Siskiyou County.

The Liberty quartz ledge on Cherry creek, worked by Hahn & Ohm, was an abandoned claim, reopened by the present owners, who, after sinking on the old workings, took out $4000, the quartz yielding $45 per ton. They are now running a tunnel 600 feet to strike the ledge.

Work is to be resumed in the Cherry Hill quartz mine on Cherry creek, says the Yreka Journal. This mine is equipped with a mill and compressed air machinery, all of which will be run by electricity, now available by the Siskiyou Electric Power Co., extending through that section to Scott Valley.

Gisang & Co. are working rich diggings 2 miles from Garretson's springs, at head of Beaver creek. It consists of both quartz and placer. There are about 12 feet of snow in the mountains, which will afford a good supply of water for spring and summer operations.

The Pine Grove claim on the bar at Quigley's ranch, in Riverside district, Klamath river, has been pumped out, and the miners are at work.

The Punch Creek mine on Humbug, recently bought by G. W. Grayson and now known as the Mono mine, has been sold to a San Francisco company, with Mr. Newcomb at the head.

The McKean M. Co., at South Fork of Scott river, near Callahans, intends sinking a new perpendicular shaft 200 feet. The quartz from the McKean mine has been successfully worked by the cyanide process. A large number of men will be employed.

The Ashland Tribune says LaShells & Kobb will put in a dredger 9 miles south of Hornbrook. The machine will have a capacity of 2400 yards a day. The lumber and machinery is already at Hornbrook. They expect to have the machine in operation within six weeks.

Trinity County.

It is reported from Coffee Creek district that a landslide recently swept away the mill, concentrators and air compressor at the Wagner mine. The men employed at the property were not at the mill at the time the slide occurred. The mill is buried in debris.

Tuolumne County.

The Confidence mine at Confidence will start operations on a large scale as soon as the weather and condition of the roads permit hauling wood and timber.

The Black Hawk mine, near Soulsbyville, has started up for the season. A steam pump is unwatering the mine.

The Draper mine, near Soulsbyville, will resume operations. A small crew is cleaning ditches and fixing up top works.

The Seminole mine, south of Tuolumne, is being unwatered for examination. The work is being done under direction of H. M. Stanley.

It is reported that Wilson & Cullers have struck good ore in the Little Beauty mine, near Arrastraville. The vein shows free gold.

The Black Oak mine at Soulsbyville is putting more men to work and in a short time will be running full-handed.

COLORADO.

(Special Correspondence). — Unsettled weather has delayed placer operations in several districts. In Breckenridge and vicinity much development work is being planned by the larger companies, and it is believed the coming summer will be a busy one in placer mining.

The judgment for nearly $500,000 of J. Doyle against J. F. Burns of the Portland G. M. Co. has been reversed and decision rendered in favor of Burns by the Iowa Supreme Court. Burns and Doyle were partners in mining for a number of years, and during the partnership the Portland mine of Victor was discovered. Doyle brought suit for the recovery of nearly $1,000,000, which he claimed was due him from Burns. He secured judgment in the lower court of Iowa, where the suit was brought, but the higher court reversed it.

The latest move in the strike situation at Telluride is the decision of Judge Stevens at Ouray ordering the arrest of General Bell and Captain Wells for not producing Moyer of the Federation in his court when ordered to do so.

Denver, April 12.

Clear Creek County.

The Chicago Mountain M. & T. Co., which is driving the Three Friends tunnel into Chicago mountain, near Idaho Springs, has cut a 3-foot body of concentrating and cyaniding ore, which assays $7 to $12 a ton gold. The tunnel is in 175 feet, and will reach the Three Friends shaft in 30 to 40 feet. The intention is to raise to the shaft.

Progress on the Grass Valley tunnel of the Santa Fe Mountain Gold Mines Co. continues, and is in 190 feet, having cut several veins. The breast is said to be in ore that assays $800 a ton.

Work is progressing in the Baltimore tunnel, owned by the Hazleton Con. Co., near Silver Plume. A vein 8 feet in width has been cut by this tunnel. The Santiago group, owned by this company, has men at work developing in all its levels and blocking out ore. The company will build a mill at the Baltimore tunnel for treatment of the ores from these two mines, and will also build a tramway from the Santiago group to the mill during coming summer.

The Waldorfs' holdings on McClellan mountain, viz., the Tobin, Commonwealth, Kitty Owsley, Paymaster and other properties, are in bonanza. The Stevens mine on the western slope of the mountain and the main workings of the group, have produced about $1,500,000. A mill of fifty tons capacity was erected last fall to handle the ore in stopes and dumps; finding them to contain so much ore the mill has been enlarged to 100 tons capacity, and will be running full time in a few days.

The Mary Etta group, which has been steadily developed the past eleven years, has justified a tunnel from the base of the mountain to tap the group at great depth. The average of the ore from this group is $144 per ton, principally in gold. The Santiago has a large amount of ore ready for treatment.

On the Indiana group, west of Daisy gulch, they are now crossing the porphyry with good values all through. On reaching the west vein a bonanza is expected, as surface workings showed rich ore there.

The Robert E. Lee tunnel, being driven by the Southern M. & M. Dev. Co., will cut many lodes that have produced fine surface pockets. This tunnel is also being driven on a porphyry dike that for 15 feet wide is mixed with iron and contains good gold values.

Fremont County.

It is reported at Florence that the Colorado Fuel & Iron Co. will reopen the Canfield coal mine at Coal Creek. This property has been idle since the coal strike was declared. It will be worked with non-union men. It is the oldest coal mine in the county.

Gilpin County.

At the Old Town mine, in Russell district, near Central City, shipping has been delayed on account of the lowering of an engine from the 600 to the 1500 station and putting in a new pump and air lines. Manager Kimball says the new electric transformer and motor for operating the new compressor, as well as the electric lighting of the top plant and workings, will soon arrive. Manager Kimball has ordered a 25 H. P. hoist, to take the place of the steam plant at the Wautauga mine, which will be operated by electricity from the Old Town mine. The property made an output of $160,000 in 1903.

Two cars of $100 smelting ore were shipped from the Fairfield mine to Denver last week, and three carloads of concentrating ores from the Waltbam mine, in Russell district, were shipped to the Alpine concentrator at Idabo Springs, and one carload of smelting ores from the Twolon M. Co.'s 2:40 mine in Willis gulch; also shipments by leasers on the Saratoga mine, in Russell district, to smelters, and several cars of concentrating ores from the Old Town mine to mills at Idabo Springs.

Good ore is being opened up in the St. Louis extension claim of the Newfoundland group on Gunnell mountain, owned and operated by G. W. Mabee, Sr., of Denver. During the past week free-gold ore was found in the 600-foot west level, and in the 500 east level there is ore assaying $150 to the ton. Work is being carried on in the 450 level and there is ore in all of the five levels, the ore body in the 600 level having been opened up for a distance of 100 feet. Its past records show a production of about $200,000, principally in gold.

A steam pump is being installed at the main shaft of the Haseltine property, on South Willis gulch, and it is the intention of the Druid M. Co. to unwater the shaft and get ready for operations at as early a date as possible.

The Perigo mill started up Monday, says the Register-Call, and is running on leasers' ore from the Perigo property. It is expected there is enough ore on hand to keep the mill running. The last run made cleaned up better than previous ones.

Lunwall Bros. have opened up copper-iron ore in their Copper King property on Lump gulch, also ore showing lead.

The Gold Dirt mine is getting in shape for regular shipping. Some ore has been uncovered in the lower levels which show increased values. When the Moffat road reaches Rollinsville this property will become a regular shipper.

Willard & Heitman have at their Swear Off lode in Lump gulch, near Rollinsville, at a depth of 70 feet, a 5 foot crevice, 4 feet of which is a good milling ore. The lessees are trying to reach the 100 foot point before they are troubled with surface water. They recently put up a whim and shaft building, but they will install a steam hoisting plant later.

W. Kelly has three men at work on the Claudia J. on Tip Top mountain, crosscutting south at a depth of 110 feet in the Millie B. shaft to cut the Claudia J. and Stewart veins. The Millie B. shows milling ore, which will be left standing until the other veins are reached. Ore shipped to the sampling works from the Claudia J. has given ten ounces gold to the ton.

Ten stamps are dropping at the new mill of the Blue Grass M. Co. at Phœnix, on the dump of the Champion property.

Hinsdale County.

The management of the Contention mine, near Lake City, has bought concentrating machinery, consisting of crushers, rolls, tables and slimers. J. D. Kazar, superintendent, says during the installation of the machinery the Mayflower tunnel will be enlarged.

Kilvert & Watkins have shipped a carload of concentrates from the Golden Fleece mill.

D. M. Jamieson, superintendent of the Hanna Co.'s mines at Capitol City, says there are forty men at work for the company and more will be added. One of the batteries is closed down for repairs. At the mine large ore bodies are exposed above level No. 3. The system of concentration at the mill is working smoothly.

Lake County.

The mines of Leadville district for the month of March show an increase in production over a year ago, and the month of April will show a further increase. The opening of spring shows a renewed activity in the outlying districts, while in the properties already working there is a large amount of new work under way, with an increased tonnage, says the Denver Republican. In the zinc production it is predicted that there will be a still further increase over last year. E. Anderson, who is looking after the zinc situation for the United States Zinc Co. of Colorado, is closing important contracts here. Mr. Anderson says that the company contemplates the erection of a concentrating and a separating plant in connection with the zinc mill at Pueblo.

The Iron-Silver M. Co. reports that both their shafts, the Moyer and the North Moyer, are making a large production, and shipping more ore than for a long time. The Moyer properties are the heaviest producers in the Leadville district, the average production amounting to 11,000 tons a month. The Moyer people are making a systematic development of their property on Iron hill. The North Moyer shaft, the new shaft placed in operation the first of this year, is taking out a good grade of iron sulphide ore. The production will run about 4800 tons of zinc ore, 1000 tons of zinc lead ore, 4000 tons of iron sulphide and iron bearing ore. In addition to this, 2000 tons a month is coming from the mill.

A series of drill holes has been put down in the section southwest of Leadville, which show the existence of the regular ore-bearing horizon of blue lime and porphyry over a mile southwest of Leadville. The white porphyry was cut 40 feet below the surface and blue limo at 680 feet, with mineralized contact showing gold and silver. This discovery opens up for development several square miles of territory.

The developments of the year are not to be confined to silver, lead, zinc and iron properties. It is reported that an extensive movement is being organized for work in the gold belt. J. J. Brown has been laboring for the past few months to obtain control of a large group of properties in the gold belt, near Leadville, and has succeeded in securing the control of extensive territory, which it is the intention to develop.

San Miguel County.

The delegation of 100 deported Telluride union miners who have been living at Ouray since their eviction from Telluride returned on the 9th inst. Word of their departure from Ouray had been received at military headquarters, and Adjutant-General Bell, in command of the troops, ordered out the military force, eighty men. Under the direction of the officers, the unionists were separated from the other passengers on the train, searched and lined up along the station platform. When all had left the train they were marched, under escort of the troops and the citizen guard, to the opera house, where they were given supper. At 9 o'clock they were returned to the train, with the exception of eight. General Bell and a detail of thirty soldiers also boarded the train, which started for Ridgeway, the first station out from Telluride.

The Japan group of mines in Savage basin, near Telluride, is under steady development. A crosscut tunnel, 2700 feet long, last season cut the vein at depth of 840 feet below lowest level in upper workings. During the winter a drift has been started on the vein east from intersection, and after it has been driven 160 feet or to a point directly under the bottom of a shaft sunk from the upper workings, a raise will be made to connect with the shaft. The raise will be 460 feet, and it is expected to have the connection made by July 15. The Japan vein carries a shoot of mineral 1 to 3 feet in width, running in gold, silver and lead.

Summit County

The Result group, near Kokomo, it is reported in Mayflower Gulch district, has opened up a fine streak of solid lead ore. C. Andorson has been working this property all winter with three men, driving the tunnel 300 feet. He has cut a streak of solid galena running across the tunnel and is now drifting upon it. He is also driving the main tunnel ahead to cut the lime formation where he hopes to cut another ore body. Snow is too deep for shipments to be made.

The Gold Belt, near Kokomo, continues to take out high-grade gold quartz. Assays show 11 to 14 ounces gold per ton. A great amount of snow fell recently and will prevent shipments for several weeks. The Gold Belt was opened up late last fall.

It is reported that the Union group on Gold hill, near Kokomo, is to start up. M. Gagan, manager, is now in Denver to make arrangements.

Preparations are making to resume dredging near Breckenridge, says W. W. Dyar, superintendent of the American G. D. Co.

Teller County.

The Stratton's Independence Co. shipped during March 4650 tons of ore averaging $30 a ton. The ore is coming from levels one, two, five, six and seven. The grade is above the average shipped from this property for months.

La Belle plant at Goldfield, it is reported, will double its compressor capac-

ity. The company now furnishes power to neighboring mines for fifty drills.

The flow of water from the El Paso drainage tunnel is now 6800 gallons per minute. The flow increases as the tunnel advances toward the Elkton mine.

Eakins & Co., who have five years' lease on the White Horse workings from the 900 level to the surface at Victor have made a shipment of twenty-five tons, estimated to he worth $30 a ton. The ore shipped came from a drift at the 350-foot level. Plans have been drawn for the cyanide mill which is to he erected at the mine, according to one of the conditions of the lease, for the treatment of low grade and dump ore. The construction work will be commenced before the end of he month. Work is to begin on the Deadwood of the United G. M. Co. at Victor.

Lessees who have a hlock of the Anaconda estate, near the Anaconda depot, have their shaft down 75 feet and are sinking with two shifts of four men each. The shaft is 4½ by 9 feet. They will sink to 500 feot before lateral work is started.

In 1902 the Last Dollar at Victor ceased operations at a depth of 1200 feet. The mine at that time was making eighty-five gallons of water a minute and the management decided to confine operations to the upper levels. Since the drainage tunnel has tapped the Beacon hill water course the water in the Last Dollar shaft has entirely disappeared and Manager Waldron has resumed sinking, having made 70 feet helow the starting point. There is no water in sight and sinking is to be continued to 1300 feet. Ore continues downward and is showing in the bottom. Manager Waldron also says that he has lately found a new shoot at the 900 level for which he has been searching for three years. The vein at this point is 4 to 5 feet wide with a pay streak ahout 16 inches in width. The mine is shipping 1000 tons a month of a better average value than at any time during the previous six months. The washer works satisfactorily; all the waste and ore is put through the washer and slimes saved which are high grade.

Murphy & Hamlin, lessees of the Isabella mine of the Isahella M. Co. on Bull hill, Cripple Creek district, are making a record for rapid driving with two shifts, under contract. In a month the contractors have advanced the crosscut 200 feet, an average of 6⅔ feet a day. It may he a month before the vein is encountered. Yet the lessees helieve it may be cut at any day. They are drifting for the Empire State shoot opened in the Maloney workings.

Thirty-five tons were sent out the latter end of last week from the Glockner & Co. lease on the Old Mallory shaft on the Empire State, now merged with the Isabella Co., says the Record. The ore was graded; controls from the local sampler show values: No. 1, $25 a ton; No. 2, $52 a ton; No. 3, $205 a ton; No. 4, $9540 a ton. The hulk of the ore was of the two lower grades.

Lessees are contemplating extensive work on the C. O. D. on Poverty gulch and are overhauling the machinery. The mine in the earlier days of the camp was a heavy producer. Water hampered the French owners, and although powerful pumps were bought they were never operated. The water has entirely disappeared through the various drainage tunnels and the mine is now dry.

The high-grade shipments from the mines on the west slope of Beacon hill are attracting attention to various unworked claims on the hill. An Eastern syndicate with a representative in the district is now attempting to close a lease in this section, and his company is prepared to expend a considerable sum in development work, hut declines to negotiate for ground under a less period than three years.

GEORGIA.

Cobb Coonty.

(Special Correspondence).—The Kennesaw M. E. & D. Co. own the Georgia Bell gold mine, 7 miles from Acworth. The property consists of 240 acres. The improvements on the mine consists of a 30 H. P. hoist, 40 H. P. hoiler, 60 H. P. engine, and shop with all required modern tools and appliances. The mill consists of one grinder 40 tons capacity, one amalgamator 100 tons capacity, a 10-stamp mill, two concentrators and a Gates rock crusher, automatic feeders, all constructed so that when the miner shovels the ore into the hucket it is not touched hy hands any more. The developments of the mine consist of twelve shafts about 30 feet deep for a distance of 1¼ mile iu length and 600 feet in width, all in ore and on five different ledges. The main working shaft is 65 feet deep. At the hottom of the shaft there is one drift in 45 feet south cutting ore, one drift east 65 feet in pay ore. J. H. Brown is superintendent. There are many other good properties in both Cobb and Cherokee counties that will later develope into good paying mines.

Acworth, April 8.

IDAHO.

Blaloe Coonty.

(Special Correspondence).—During the '80s the towns of the Wood River valley were the center of an extensive silver-lead mining district. Twelve years ago the greatest producers were closed, since which time the country has been quiet, but within the last two years many of these old claims have heen reopened. Of these old properties the Minnie Moore, 1½ miles west of Bellevue, was one of the largest producers. It was owned by Englishmen who, after taking out several million dollars, thought they had exhausted it. In this county there is a fault or break in most of the silver-lead veins and they had struck this hreak, and, not understanding mining geology, abandoned operations. Three years ago the property was bought by Eastern men, and, under the systematic management of I. E. Rockwell, it has taken its former place among the great producers. After taking the water from the mine, a crosscut was run on the 900 level and an ore body cut containing, approximately, a gross value of $2,000,000. The main ore shoot now exposed is 350 feet long. The first-class ore at the 1000-foot level is steel galena, from 1 foot to 9 feet wide, and samples 70% lead and 110 ounces silver per ton. The second-class ore is concentrated four tons into one, and runs ahout 55% lead and 60 to 70 ounces silver. All the ore thus far produced has come from one claim less than 1400 feet in length. Recently, while the men were at work, the water commenced to come in from the bottom. It rose so rapidly that the men were compelled to abandon one of tho pumps. The water rose rapidly for about 300 feet and then the pumps were ahle to check it, and it was finally pumped out. Evidently a large underground reservoir had been cut.

Hailey, April 6.

Idaho County.

(Special Correspondence).—On the H. Y. group the tunnel on the Dakota claim is in 200 feet, the values running from $1 to $16 per ton. The second payment on the purchase price of the group has been made and a discount for cash is being considered hy the owners. Sinking of the 100-foot shaft on the Climax is making good progress. The Diamond Chief Mining Co. has heen organized at Asotin, Wash., to operate a group of sixteen claims on the west fork of Monumental creek, which includes a fine town site in Thunder Mountain district. The driving of two tunnels has been under way all winter, under charge of J. Cassell. Each tunnel is in 60 feet. and they will he continued 200 feet to get into solid formation. Ore giving good assays has heen taken out. The company also owns a group of claims at Copper Camp on lower Big creek, where developments are heing made hy G. Brewer and Babendorf Bros. On the Black Bear claim a 12-foot ledge has been uncovered, carrying 6% copper and $8 in gold per ton.

F. S. Allison of Sugar creek says the 300-foot tunnel on the Pickwick group is ahout half completed. A crosscut 50 feet each way from the 150-foot station shows ore from the face of the left drift worth $47 per ton. Considerahle active work is being done on and near Sugar creek.

The Blue Bird group of five claims on McCann creek has one ledge of white quartz porphyry 35 feet wide carrying values of $3.50 per ton. Another ledge 30 feet wide of dark ore, between granite walls, has 4 feet of talc on each wall that gives a value of $4.80 per ton, the entire ledge giving from $3.50 to $4.80 in gold.

The Confidence group of seven claims on Gold mountain, half a mile from Sugar creek, is sold to Mr. English of Omaha, Neh. It has a 30-foot tunnel on a 12-foot ledge running $6.40 to $8.75 per ton. The Independence group of six claims owned hy F. B. McCann of Lucile, Ida., lies hetween the Confidence and Blue Bird groups. A 60-foot tunnel is driven on a ledge from 80 to 100 feet wide between granite walls, and has values running from $4 to $6 per ton in gold. The crosscut tunnel on the Burr Oak claim of the Sunnyside group is in 1200 feet and has encountered quartz-porphyry, which is helieved to indicate an approach to the ore hody developed in the north drift of the upper tunnel.

Roosevelt, April 5.

At Hump, the Jumbo's March cleanup is stated to have been $15,000, the largest in the history of the camp. This hullion was from the plates, and between $4000 and $5000 in concentrates are ready for shipment or cyaniding.

The Wise Boy mine is working several men in the lower tunnel and is making a good showing.

The Crackerjack, in the Buffalo Hump camp, is working twenty-five men. In the lower tunnel they are opening a large ore body that has been tapped above. The property has a 10-stamp mill.

The Lucky Lad, operated hy Seattle people, has increased its force and sunk 150 feet. It has from 8 to 12 feet of milling ore.

The Atlas, owned hy Spokane people, is sinking and is down 175 feet, working twenty men.

Owyhee County.

(Special Correspondence).—An important strike is reported on War Eagle mountain, parallel with the Golden Chariot lode. J. Hogan and K. H. McLeod made the discovery. These experienced prospectors found rich float and started a shaft, and found a pay streak 18 inches wide, the ore running, it is thought, $750 in gold. They have fifteen tons out and a mill run will he made as soon as conditions permit.

J. Beaton has been running a tunnel the past four years on his claim—the Industry — adjoining the Empire mine. When in 300 feet a 3-foot vein was crosscut, with a pay streak of 18 inches, the ore running from $100 to $1000 in gold. He has ten tons sacked, employing two men to assist him.

Preparations are heing made to work the Fourth of July group this season. This property is a recent location and remained unnoticed for years, the surface being capped with rhyolite. In following the course of the Golden Chariot vein the discovery was made hy Hogan, Connors & Evans. A shaft was sunk, showing the vein to be 8 feet wide. The entire vein matter will average $10 in gold, which can he recovered at an expense of $2.50 per ton.

The Poorman Gold Mines, Ltd., it is reported will be consolidated with the Sinker Tunnel Co for the purpose of more economical development. The latter company suspended operations a year ago. The reported consolidation and the new strikes made this season are encouraging to individual claim owners and a lively season is anticipated.

The Trade Dollar Con. M. Co., operating on Florida mountain, shipped 1000 pounds of bullion to the mint tbis week. This is a portion of the monthly production, as 25% of the values are contained in concentrates. This property has ore reserves in sight, it is said, to keep the mill at Dewey running for two years. The large tunnel is in nearly 2 miles, with another mile to be run before completion. The company has received eight more elcctric transformers, which will be utilized in the haulage plant. The property has produced $10,000,000. F. Irwin is general superintendent, J. B. Mattenson foreman, J. Inglis master mechanic, and E. C. Given chief clerk. The company employs 250 men, and wages are $3 per day for miners, $3.50 for machine men and $4 for mill foreman and mine bosses.

The Trade Dollar Extension M. Co., adjoining the Trade Dollar, is doing extensive development work, two tunnels heing driven to cut the veins. Several huildings are completed and electric machinery will be in place in a few days. The property shows high values in gold on the surface. The property is owned by Salt Lake men, who are having the group patented. W. Williams is mine manager and A. F. Stevens consulting engineer.

The De Lamar mine is producing 100 tons a day, the ore heing treated hy the cyanide process at a cost of $2.50 per ton. This property was reputed to be worked out four years ago and now has over two years ore in sight. It has produced between $10,000,000 and $11,000,000. E. V. Orford is general manager.

The old Flint district, 9 miles southwest of Silver City, promises to be active this season. The mill, which has been idle for a number of years, is again to he put in commission, and several men will he employed. The White Bros. and D. Adams have a small mill in operation, which is run in the spring during the water season. They have some high-grade ore.

South mountain promises to be lively the coming season and is attracting attention on account of the high-grade argentiferous ores. The American Standard M. & M. Co. is making preparations to work their property on an extensive scale and will he on the ground about May 1 to commence operations. This company had a carload of high-grade carhonate ore ready to ship last season, hut was prevented on account of the roads not heing completed until too late in the fall. T. F. Walsh of Denver is president of the company and F. T. Clemmons will he manager. What is needed most in this camp is capital to properly develop the district.

Dewey, April 6.

Shoshone County.

Two feet of ore has heen opened in the lower tunnel of the Trade Dollar, at Burke. The strike was made when the tunnel had heen driven 1300 feet. At first there was only small stringers, but it has opened up into a well defined ledge, with 2 feet of good milling ore. This is at a depth of 700 feet. The Trade Dollar is on Gorge gulch, half a mile from Burke, and 1 mile south of the Hercules mine. The principal stockholders in the company are C. Amonson, A. P. Hunter, B. O. Skonnard, M. C. Peterson and A. Shoff.

The new electric power plant at the Hercules mine, near Burke, will be in operation this month. The mine is working 120 men. The new power plant will supply the mine with electric lights.

After a closedown of several weeks, during which time a hoist and pump were installed, the Evolution mine, the first location made in the Cœur d'Alenes, has resumed development. During the winter seven men have been sinking a shaft to tap the ledge at a depth of over 200 feet. When the creek level was reached water was encountered, and it was necessary to install a pump. The shaft will have to be sunk 150 feet more hefore the ledge is encountered. The Evolution was located by A. T. Pritchard in 1878. The ledge that has been uncovered abovo tho shaft has returned values in gold, silver, lead and copper.

Lessees of the upper workings of the Snowstorm, near Wardner, expect to hegin shipments of copper ore to the Tacoma smelter. Development has disclosed high grade silver-copper ore.

MONTANA.

Fergus County.

G. M. Anderson of Maiden bas secured a lease on the Maginnis mine at Maidon and has struck high-grade shipping ore. He hegan work in the mine several weeks ago and found a good grade of milling rock, but not carrying values sufficient to ship profitahly. Since then in a winze off the main tunnel he has discovered a body of high-grade ore.

In Tilden gulch, on east slope of the range, in Cone Butte section, near Lewistown, the Case-Wilson Cyanide Dev. Co. is working the Tilden gulch group of ten claims, which the company has under bond. Seven men are working on this group, and during the winter 550 feet of development has heen done. Low-grade ore hodies are showing in the workings, particularly on the Myrtle and Daisy lodes. A mill will be added to the group during the summer. On the Myrtle a crosscut tunnel is heing driven for exploration. This tunnel has reached 180 feet. The ore of the Tilden gulch group is a cyaniding proposition on the surface, but in the deeper workings much of the ore is impregnated with fluorite. Losinger, Daugherty & Pender have the Laura B. and other claims adjoining the Tilden group on tho west.

NEVADA.

Esmeralda County.

At Goldfields, the new camp west of Tonopah, the January and Jumbo lessees are shipping five cars of ore weekly to Reno. It is reported to run over $300 per ton.

Lincoln County.

(Special Correspondence). — The Nevada Copper Co., in Yellow Pine district, is driving a crosscut to tap the ore shoot developed on the surface. The tunnel will tap the vein at depth of 300 feet. —— It is reported that the numher of men on the Green Monster will he increased. This property is 8 miles northeast from Sandy, which is the base of supplies. The mine is located on a lime contact which can he traced for ahout 1 mile. On the property are three shafts down 350 feet; also levels from the different stations cutting bodies of lead carbonate and galena, carrying good values iu silver. The ore also carries copper. Throughout the mine copper glance is found which is rich in silver. The accompanying spar also carries some values. An ahundance of water is obtainable about 1 mile from the mine, and with the Salt Lake railway now nearing completion the profitable working of the propery now seems assured.

The Nevada-Keystone M. Co. has issued thoir report for the last quarter of 1903, which shows a total of 1280.8 tons of ore milled, from which was recovered $29,298.85, besides values recovered by cyanidation of tailings. The total amount of development work during this period was 900 feet. The new working shaft has reached the 670-foot level, showing ore at the hottom which assays as high as $100 per ton. The 540-foot level has been driven 200 feet through a continuous ore shoot. This level will tap the hottom of the old incline in ahout 30 feet more. The main tunnel is heing pushed ahead to prospect the Honduras claim adjoining

the Keystone. Twenty-five men are employed in development work. On January 20th the regular semi-annual dividend was paid, amounting to $19,325, making a total of $42,623 of dividends paid since September, 1902, at which time the present company started milling. C. Andersen, E. M., is the general superintendent of the property.

Sandy, April 12.

The Searchlight M. & M. Co. is running a drift along the foot wall of the vein, now in 40 feet.

Two miles northwest of Searchlight, in the low hills running up to Pinto mountain, is the property of Onkey & Conley. They are down 40 feet and have a 3-foot ledge. The vein all "horns" and there is a streak in it of high-grade ore.

The Empire Co., near Searchlight, has a millsite surveyed at Empire Camp. The company intends running a 500-foot crosscut from above the millsite to tap the Empire lead. A mill is contemplated.

The latest water strike at Searchlight was made last week by the Pompeii M. Co., operating the Miess property. The strike was made in the main shaft at a depth of 262 feet. An 8-foot sump has been cut and a west drift is being run, from the end of which crosscuts will be run.

The Quartette mill at Searchlight has been closed down for several days while a change of engines was made. A new 40 H. P. gasoline engine has been installed and the old engine moved to the electric room, says the Searchlight. The electric plant adjoins the mill. The plant will furnish power for lighting the property above and below ground and also for operating the pumps. The elevated platform for the six settling tanks is up and the tanks will be set up in a few days. Superintendent F. J. Harrington is taking advantage of the close down of the mill to straighten the shaft.

Nye County.

On the 800 level of the Belmont mine at Tonopah the west drift on the hanging wall is out 25 feet and shows 5 feet of shipping ore. The east drift on the foot wall is out 40 feet and producing a good grade of milling ore. The ledge is 28 feet wide where crosscut.

G. Zanoli last week shipped ten tons of high-grade silver-lead-gold ore from the Rabbit mine at Ely to Selby's Smelting Works, says the Eureka Sentinel.

The McNamara mine at Tonopah is crosscutting through mineralized country rock, which is there considered an indication of proximity to a vein.

The January lease at Goldfields is hoisting thirty tons of ore daily. The sorted first-class runs $200 per ton.

It is reported that J. Campbell has cut 4 feet of $90 rock on a claim southeast of Gold mountain.

In the United-Tonopah a streak of shipping ore has come in on the hanging wall at a depth of 290 feet, says the Bonanza. The remainder of the vein carries gold in milling values.

White Pine County.

It is reported that rich finds of silver and gold ore have been made at Dolly Varden, a camp near the Utah line.

OREGON.

Baker County.

The 20-stamp mill for the Belcher mine, near Baker City, is now being shipped to Whitney. Superintendent Brady expects to get the machinery to the property before the roads soften too much.

Gold ore running $40 per ton is reported near Austin. The formation in which the vein occurs is said to be phonolite. The new strike is near the Wisconsin, and is known as the Oro Fino.

A compressor of 6-drill capacity is to be put in at Midway, near Sumpter. Manager Hendryx says the work will be carried out as soon as climatic conditions permit. The compressor will be run by steam. The present plant generates 125 H. P., which runs the hoist, pumps and compressor. The shaft is below the 200 level and a station will be cut at the 260 level.

It is proposed to put in a grinding machine in the Dixie Meadows mill, near Sumpter, to crush the ore from the rolls, which work to 16 mesh. Only 20% to 30% of the values in the ore are free milling, and it is now proposed to crush finer and concentrate.

The strike at the E. & E. mine, near Sumpter, has been settled and the mine has resumed, though not full handed, as some repairs and changes are to be made.

A report from Granite says rich ore has been found at the Cougar, under direction of I. Nail. The ledge measures 7 feet.

The I X L mine, near Greenhorn, which has a 2-stamp mill, is reported to be taking $300 per day from the plates and is shipping ore that averages net over $800 per ton. The last car shipped brought $13,000 for twelve tons, making the production $20,000 per month.

The machinery for the New York Con. is going in and will be in operation by May 1.

Douglas County.

The Oregon Securities Co. at Bohemia reports increase of work projected, both in mine and for the railroad. The tunnel will be completed by Aug. 1. It is in 300 feet into Champion mountain, through which it will be run to make connection with the Musick mine, allowing the ore to be hauled by electric tramway from that producer to the mill built in Champion basin. Running this tunnel will cost $12,000 to $15,000, says G. B. Hengen of New York, president of the company, but by so doing they will crosscut two veins of ore already known as producers. The first one is the Excelsior, which will be cut at distance of 150 feet from present face, and the second, the Champion, will be reached at distance of 350 feet from face. The tunnel when completed will be 1500 feet long, and will be large enough for a railway train to pass through. When the Champion ledge is cut it is intended to follow that vein the entire distance through the mountain, securing ore for milling. As soon as the tunnel is completed ore can be obtained from the Musick mine, but until that time they will use ore from the Champion mine. Three air compressors, with drills, are in operation. As soon as the snow clears they will get the road in shape from the Musick mine, the rails being already on the ground. The electric plant is completed. Connections for electricity have been installed. The railroad will be completed by May 1 to the warehouse, where the electric plant is built. It is then intended to put in an electric car line from there to the mill. The distance is 5 miles.

Josephine County.

The Allen mine, a gold-copper property, on Rogue river, 3½ miles south of Galice creek, is reported sold to C. d'Autremont of Duluth, Minn., for $750,000.

SOUTH DAKOTA.

Lawrence County.

March averages at the Spearfish G. M. & R. mines, in Ragged Top district, were a dollar better than those of February, being $5.50 a ton. February, however, was a month of profit, $21,000 having been turned out during that month. The average value of February ore was $4.68; the average recovery $4.46, showing an extraction of 95.4%. The net profits were between $9000 and $10,000. This was on ore extracted in the course of development. A header has been started toward another ore body, making six drifts for exploratory purposes. All are in ore.

Arrangements are being made by the Clover Leaf Co., near Perry, for the sinking of the shaft to 1000 feet depth. A small hoist will be installed at the bottom of the shaft at 700 feet to be used in sinking. The large engine at the surface has all the work it can do in hoisting ore and rock broken in development on the proper levels. Improvements are being made in the mill.

UTAH.

Grand County.

F. B. Hammond reports another strike in the Blue Jay, adjoining the Big Indian mines, near Moab, says the Tribune.

In the Stone Cabin group, owned by Mr. Hammond and associates, 20 feet of copper ore is opened that will average 7.5% copper, with some silver. The group is near the Paradox mines.

The Big Indian group is owned by C. E. Loose, Gov. Wells, the L. Taylor estate and J. Skowes.

The first cyanide plant in the La Sal region is about to be built by the Interstate M. & M. Co., 20 miles southeast of Moab, says J. H. Clark, superintendent. The ore is reported to average $7.50 gold per ton. Trials have demonstrated that the cyanide process is adapted to the ore.

On the Grouse Mountain group Superintendent J. W. Wheat has opened up 20 feet of similar ore.

The uranium deposits in the same locality continue to attract attention, with a prospect of extensive development.

Tooele County.

W. P. Richards, of the Utica group, on Dutch mountain, in the Deep Creek section, says another gold discovery has been made in that locality, in territory acquired by himself and associates in the Utica. Recently the manager, while looking for a suitable site to begin a shaft, found the rock rich in gold.

The Sacramento mine, at Mercur, has about $13,000 worth of quicksilver on hand reduced from the mercury-gold ores of that mine. The gold is obtained by cyanidation.

Utah County.

March, in the ore and bullion market, closed on settlements aggregating $2,013,600, with copper bullion output from furnaces independent of those operated by the American S. & R. Co., increasing the output to $2,911,357, says the Salt Lake Tribune. During same month last year settlements in the open market amounted to $2,029,540, with the total from all sources of $2,780,000. The output of copper bullion containing gold and silver from furnaces aside from those of the American shows total of 2,958,990 pounds, compared with 2,921,642 pounds for same period in 1903, as follows:

	Pounds.
Bingham Con.	727,190
United States	1,023,400
Utah Con	1,208,400
Total	2,958,990

In addition to this copper bullion the American S. & R. Co. forwarded matte containing 765,000 pounds of copper, increasing the total copper bullion to 3,723,990 pounds. The output will be still further increased as there are enlargements going in at plants now in operation and new plants in process of construction. Equipment at the United States will take care of the increased output of lead ore, but a sixth furnace being added to its battery will add to its facilities for reduction of copper ores, while in June the Utah Con. will be reducing 50% more, and the fourth furnace at the Bingham Con. is ready for operation.

WASHINGTON.

Ferry County.

(Special Correspondence). — Three months of the new year have gone and the promise of progress in mining has not materialized. At the beginning of the year the opinion was general that ere this the boom of prosperity would have been launched. That this is not the case cannot be attributed to any fault of the mine managers. The mines are sufficiently developed to furnish a large tonnage of ore daily. The real cause is inadequate treatment facilities. The smelters have been unable to take more than 50% of the possible output of the mines and, therefore, the mines could be operated only in a small way. This fact also prevented the opening of new mines, as it was useless to do so if no market could be found for the ores. The hope of the camp at the beginning of the year was the Heudryx process. When the Mountain Lion Co. began the erection of a plant to test the ore by the new process, it was believed that it would prove a success. There was much delay in getting the machinery started, and when started there were the usual drawbacks incident to the installation of new machinery. A test run has been made of 150 tons. The figures have not been given officially to the public, but it can be said with safety that the test was satisfactory, and it is reported that the Mountain Lion Co. will install machinery to handle 100 tons per day. Should it do this, no doubt others will do the same, and mines which have been shippers in the past will install similar plants. It is probable the results of the test in the Mountain Lion plant will soon be made public. Meanwhile the shipping mines will continue to operate in a small way, as in the past.

The Quilp, which has sent out sixty tons per day for the past eighteen months, is continuing its output for the present. The mine is reported looking well, and opened to the 500 level. Its producing capacity is 150 tons daily, but it is probable the mine will close, as the management do not think it good business to mine such a small quantity of ore as the smelters can take. Complete success cannot be made of mining in this section until the treatment facilities are greatly enlarged.

The Belcher mine continues development. Recent assays show a value of $49.70 in gold, $2 in copper and $1.46 in silver, from an 80-foot vein.

Republic, April 7.

WYOMING.

Carbon County.

(Special Correspondence).—The North American C. Co., owning the Ferris-Haggerty and other copper properties near Encampment, are ready to start up the new concentration mill, which is equipped with breakers, rolls, tables and other accessories to the concentration of the ore.

Encampment, April 11.

FOREIGN.

AFRICA.

Transvaal.

The Rand Victoria bore hole No. 2 is now 4975 feet deep and is in slate. Boring has ceased. No new signs of reef in bore have been discovered, and it is thought the series has been disturbed by the dike overlying reefs. This bore hole cut the main reef series at a depth from surface of about 4580 feet, approximately the depth at which they were expected to be met. The bore hole, after passing through dike near the reefs, found the formation was disturbed, and the bore hole was continued farther to make sure that the whole series had been passed through. No further reefs were met, but the slate formation which underlies the main reef series was encountered in correct position, adding additional proof that the reefs previously met with were the main reef series. The fact of the reef being disturbed in the neighborhood of the dike is not an unusual occurrence. The Rand Victoria bore hole No. 2 has secured results for which it was put down, to ascertain accurately the depth at which the main reef series would be cut.

AUSTRALIA.

New South Wales.

Diamond drill prospecting, both vertical and horizontal, in the British Broken Hill proprietary, is resulting in discovery of new bodies of good grade sulphide ore, from 14 to over 60 feet wide. The mill is treating about 9000 tons monthly.

BRITISH COLUMBIA.

J. Hyland, trader of Telegraph Creek, has arrived at Victoria with specimens of gold from the latest field, the Nahani river, near the junction of the Liard and Dease rivers, northeastern British Columbia, says the Rossland Miner. The discovery was made by J. Morrow two years ago. Recently Morrow sent an Indian to try the river bed, not thinking there was much in it. The Indian, who had mined in Cassiar, made a sluice box and shoveled in some dirt, and in an hour he got a handful of gold, which he brought to Telegraph Creek. The news, it is said, has caused a stampede from all over the north, although ice and snow are heavy on the ground and water. The new field is reached by way of Telegraph Creek.

The weather conditions dominate the mining business to a great extent in this Province. During the winter shipments of ore are made from many mines by the method known as "rawhiding" over the snow, for which ore is gotten out in advance as far as possible. When spring comes, there is an interval of several weeks when the snow is too soft for rawhiding or the mud too deep for wheeling, and ore shipments come to a standstill, though if the management has provided the necessary supplies during winter, the operation of the mines can be continued. This is the season of the year when shipments to a great extent cease, owing to the condition of the roads.

Nelson District.

The Broken Hill M. & M. Co., operating the Wilcox mine, near Ymir, reports having struck black sulphurets and pyrites, carrying gold, silver and lead. The find was made in the tunnel at vertical depth of 240 feet. The ledge is 2½ feet wide and the sulphides from 14 to 16 inches wide, the balance of the vein being high-grade milling ore. The company is opening a new vein on the first level and has drifted 40 feet. In this vein there is a high-grade streak 2 feet in width. The stamp mill is kept in continuous operation. There are twenty-seven men at work. S. Bywater of Spokane, Wash., is president of the company and E. A. King of Chicago, Ill., manager.

The Reliance G. M. & M. Co., Ltd., has been incorporated by A. H. Kelly, J. A. Turner, W. P. Tierney, B. White and R. S. Lennie of Nelson. The company has bought the May and Jennie group of claims on Forty-nine creek, 8 miles from Nelson and 5 miles from the tracks of the Columbia & Kootenay Railway. Over 3000 feet of work have been done in tunnels, shafts, drifts, raises and crosscuts.

CUBA.

An extensive deposit of chromic iron ore is reported found on the coast of Cuba, 30 miles from Baracoa. It shows from 8 to 12 feet in thickness. It is said the freight rate by water will permit of its transportation.

Two companies are mining manganese ores in Cuba, according to the Mineral Resources, issued by the U. S. Geological Survey—the Ponupo M. &. T. Co. and the Standard Manganese Co., shipments being made through port of Santiago de Cuba. The Ponupo manganese mines are near La Maya, 16 miles northeast of El Cristo, the ore averaging 47% metallic manganese. The Standard Co.'s Boston mine is 3 miles southeast of El Cristo. The mine is worked by open cuts, through mixed sandstone and manganese. The ore occurs in pockets. When sorted for shipment, the ore is said to average 50% metallic manganese, and 1% to 3% iron.

FRENCH GUIANA.

The output of gold in 1903 is reported at Cayenne and St. Laurent at 4033 kilograms. Of this total 3597 kilograms were entered at Cayenne, as compared with 4645 kilograms in 1902.

INDIA.

The output of the gold mines of India for month of February was 50,151 ounces, as compared with 51,588 ounces for January, and with 46,268 ounces for February, 1903. It was distributed as follows:

	February.
Champion Reef at Kolar—	
Mill, tons	15,062
Mill, ounces	14,600
Tailings (cyanide), tons	19,400
Tailings, ounces	3,021
Total ounces	17,621
Mysore at Kolar—	
Mill, tons	15,750
Mill, ounces	14,756
Tailings (cyanide), tons	11,817
Tailings, ounces	1,661
Total ounces	16,417
Ooregum at Kolar—	
Mill, tons	10,402
Mill, ounces	5,288
Tailings (cyanide), tons	10,012
Tailings, ounces	1,001
Total ounces	6,289
Nundydroog at Kolar—	
Mill, tons	5,800
Mill, ounces	5,065
Tailings (cyanide), tons	4,825
Tailings, ounces	566
Total ounces	*5,786
Balaghat at Kolar—	
Mill, tons	2,800
Mill, ounces	2,180
Tailings, tons	2,280
Tailings, ounces	230
Total ounces	2,410
Mysore West-Mysore Wynaad at Mysore—	
Mill, tons	1,816
Total ounces	977
Hutti at Nizam's—	
Tons	960
Ounces	651

*Including 15.5 ounces from cyanide slag.

MEXICO.

Chihuahua.

The Harmon M. Co. has its shaft on the Monte Cristo, near Parral, down 150 feet and on the San Nicolas 300 feet.

The Buena Ventura Co., near Parral, has begun operations by starting a shaft and exploring the old open cuts. J. W. Pender is manager.

The third California company to operate at Santa Eulalia has begun operations on La Minerva mine. The owners are Los Angeles, Cal., men.

At Terrazas camp Dale Bros. and F. McDonald have out 800 tons of shipping ore at the Americano mine. They are taking out forty tons daily, much of which is said to be of shipping grade.

At the Quebradillas mine, near Parral, there are eleven shafts, ranging in depth from 120 to 200 feet. It is reported $1200 worth of ore is mined daily. J. W. Pender is manager.

The output of the Santa Eulalia mines is 30,000 tons of ore monthly, says the Chihuahua Enterprise. This ore comes principally from four mines, the properties of the American S. & R. Co., the Santa Eulalia Exploration Co., the Chihuahua M. Co. and El Potosi M. Co. The Mineral Railroad is hauling 8000 tons per month, principally from the first two companies named; and the Chihuahua M. Co. Railroad is hauling 12,000 tons monthly from El Potosi and Santo Domingo mines. Other mines ship irregularly as development produces ore. Both railroads are taxed to full capacity. The output is expected to be increased. The Santa Eulalia M. Co. (Hearst) has struck ore in No. 3 shaft. The Santa Eulalia Ex. Co. is hoisting ore through the shaft of the American S. & R. Co., hut as soon as the shaft of the former is completed both companies will increase their outputs. In the Parcionera the known ore body has not heen reached, but is expected this month.

Sonora.

There is considerable activity in the Sierra Tordillo country, west of Fronteras, a station on the Nacozari railroad. Many Americans are taking up copper concessions and gold and silver properties are heing opened.

The Santa Rosalia is to he worked again. This property is within 15 miles of Arizpe, the capital of the district, and 65 miles from Cananea. G. Mitchell, formerly manager of the Cananea Con. C. Co., is at the head of the uew Santa Rosalia Co.

The Phelps-Dodge Co. of New York is working on their gold property. A mill will be installed and the ore dump worked. The company is shipping high-grade gold ore. All the rock that goes $100 or less is put on the dump for reduction in their own plant.

The smelter of the Juarez Smelting Co., including the concentrators and machine shops, were destroyed by fire last week, says the Cananea Herald. A company of soldiers from Juarez were taken to the scene of the fire, but could do nothing. The smelter is 2 miles south of Juarez, on the Sierra Madre railway, and was built in 1897–8 and at a cost of $150,000. The works had heen shut down two months, owing to lack of ore.

Yucatan.

Oil fields are reported found on the Yucatan coast by G. F. Dujay et al. of Galveston, Texas. Concessions on 150,000 acres of land have heen ohtained from the Mexican Government and three of the wells drilled have proven the presence of petroleum. Dujay will estahlish a pipe line to the coast and build oil harges to market the product of the field.

NEW ZEALAND.

The total production reported for ninety-six dredgers operating in New Zealand during January, 1904, was 7400 ounces fine gold. Average yield per dredger was 78 ozs. 15 dwt., and average working time of dredgers was three weeks, showing a loss of 25% time.

Personal.

J. H. KEMP has resigned as manager of the Magnolia mill at Magnolia, Colo.

R. B. LAMB is with the North American Copper Co. at Encampment, Wyo.

JACKSON DENNIS, a mine owner of Sutter Creek, Cal., is in San Francisco, Cal.

F. H. HOOD is manager of the copper mine near Fairplay, El Dorado county, Cal.

H. A. LEE has returned to Denver, Colo., from New York and other Eastern cities.

F. M. CLARK is assayer of the Amador County Reduction Works at Sutter Creek, Cal.

J. H. MACKENZIE of San Francisco, Cal., has left Rossland, B. C., for Spokane, Wash.

W. C. HOWARD has returned to San Francisco, Cal., from mine examination in Mariposa Co., Cal.

W. D. PEARCE, general manager of the La Luz G. M. Co. of Chihuahua, Mexico, is in Los Angeles, Cal.

H. W. TURNER, E. M., has returned to San Francisco, Cal., from mine examinations at Tonopah, Nev.

H. DE C. RICHARDS of San Francisco, Cal., has gone to Sonora, Mexico, to examine mining properties.

J. H. BROWN is superintendent of the Kennesaw M. E. & D. Co. at the Georgia Belle mine near Actworth, Ga.

W. F. WENDT, manager of the Buffalo Forge Co., Buffalo, N. Y., has returned there from a trip to California.

W. SHARWOOD, a mine owner and manager of Soulsbyville, Cal., is recovering from an attack of appendicitis.

F. D. SMITH of Sumpter, Or., and manager of the Snow Creek mine, has gone to Mexico City on mining business.

DEW OLIVER, president of the Zubiate, Mexico, M. Co., has returned from Sonora, Mexico, to San Francisco, Cal.

W. F. WARDEN, president and general manager of the Burt Mfg. Co., Akron, Ohio, sailed for Europe on the 15th inst.

JOHN B. FARRISH of Denver, Colo., has returned to San Francisco, Cal., from a professional trip to Sutter Creek, Cal.

A. LUCE, C. BENHAM AND J. HARTIN of Prescott have heen examining mines owned hy the former near Hillside, Arizona.

J. H. CLARK, superintendent of the Interstate M. & M. Co., has returned from Salt Lake, Utah, to the mines near Moab, Utah.

H. C. HOLTHOFF, general manager of the Power & Mining Machinery Co., Cudahy, Wis., has returned there from Denver, Colo.

THOS. CLARK, superintendent of the River Hill mine, near Placerville, Cal., has returned to the mine from San Francisco, Cal.

F. O. WILKINSON, superintendent of the Nevada Copper Co. in Yellow Pine district, Lincoln county, Nev., is in San Francisco, Cal.

M. P. KLAVERWEIDEN, chemist, and G. H. Verloop, E. M., of Amsterdam, Holland, are spending some time in Denver and Colorado.

A. W. TAYLOR of Alameda, Cal., has returned from Corea, where he held the position of a division superintendent for the Oriental M. Co.

JOHN ROSS JR., superintendent of the Wildman-Mahoney mine at Sutter Creek, Cal., has gone to southern Oregon to make mine examinations.

THOS. CLARK, superintendent of the River Hill mines, near Placerville, El Dorado county, Cal., has returned to the mines from San Francisco, Cal.

H. HERFORD of London, Eng., representing an English company, has returned to England from Jerome, Ariz., where he bought copper prospects.

W. H. MCCORD of Guanajuato, Mexico, has returned to San Francisco, Cal., from a visit to Virginia City, Nev., where he went to inspect the large cyanide plants.

R. J. GRANT of Denver, Colo., left San Francisco, Cal., on the 14th en route to Kalgoorlie, West Australia, where he takes a position with Bewick, Moreing & Co.

J. H. FENNESSY, president, and A. H. Seep, vice-president, of the Mine & Smelter Supply Co., Denver, Colo., are in the City of Mexico on business connected with their firm.

G. F. G. SHERMAN of Grass Valley, Cal., who for some time has been assistant superintendent of the North Star mine, has accepted a position as assistant manager of the Copper Queen mine of Bisbee, Ariz.

E. H. NUTTER of Redding, Cal., has been appointed assistant superintendent of the Standard Con. mines at Bodie, Cal. Theodore Hoover, who formerly occupied the position, has heen made superintendent.

Commercial Paragraphs.

THE J. Geo. Leyner Engineering Works of Denver, Colo., contemplates the erection of a $150,000 plant at Littleton, Colo.

FROM the firm of A. Leschen & Sons Rope Co., St. Louis, Mo., is received a celluloid rope caliper, which they are distributing to their customers who use wire rope, and will he furnished on application.

J. O. DIMMICK, Pacific coast manager Dimmick Concentrating Co. of Denver, Colo., has established his office with the Lacy Mfg. Co., at 334 North Main street, Los Angeles, Cal., where he will make his headquarters.

THE Rix Compressed Air & Drill Co., San Francisco, Cal., have a contract with the Utica Mining Co. for a 400 H. P. compressor, to he placed alongside of the other 400 H. P. machine which they furnished the company three years ago.

INCREASING BUSINESS of the National Wood Pipe Co., Los Angeles and San Francisco, Cal., has occasioned the removal of Vice-President W. J. Woodward from Los Angeles to San Francisco, where he has assumed the management of the business at the company's office, 301 Market street.

THE Ore Concentration Syndicate, with offices at room 53 Crocker Building, San Francisco, Cal., has an order for one of its Elmore oil concentrating plants from the Kassandra M. Co., owner of silver-lead properties in Macedonia. The shares of this company are largely held in France. The ore has to he crushed to 60 mesh to separate the ore from the limestone gangue.

A DOUBLING of its capital stock, which has heen $1,000,000, is announced hy the Crocker-Wheeler Co., manufacturers and electrical engineers, Ampere, N. J. The company was organized in 1892 hy Dr. Wheeler and Prof. Crocker on a relatively modest basis. It now has fifteen hranch offices from Boston to San Francisco, and does a large business in electric power apparatus. The capitalization was several times increased, until in 1899 it had become $1,000,000. In view of the rapidly expanding business the stockholders have now decided to increase this amount to $2,000,000.

Trade Treatises.

Illustrated catalogue of mineral collections, Foote Mineral Co., 1307 Arch street, Philadelphia, Pa.; 25 cents.

Corliss engines and high pressure hoilers are the subject of a handsome treatise from the Murray Iron Works, Burlington, Iowa.

The Keller heater is elahorately described in a catalogue sent by the Pacific Steam Economizer Co., 711 Lankershim building, Los Angeles, Cal.

"Wireless Telegraphy and Its Wonderful Possihilities" is the suhject of a treatise from the Thos. E. Clark Wireless Tel.-Tel. Co., Pontiac, Mich.

Hydraulic dredging machinery, air compressors for heavy duty, are among the subjects treated in Catalogue D from the Great Lakes Engineering Works, Detroit, Mich.

Mining machinery catalogue No. 19 from the Jeffrey Manufacturing Co., Columhus, O., is fully up to the high standard of this company's productions, and will be mailed anywhere on request.

Bulletin No. 6, from the Jeffrey Manufacturing Co., Columhus, Ohio, written hy Frank R. Field, graphically illustrates and descrihes one of the Jeffrey electric coal mine installations in Colorado, giving detailed items of cost and operation. Bulletin No. 7, hy C. B. Peck, also shows the value of electric haulage as compared with mule haulage.

Books Received.

"Quantitative Analysis, for Mining Engineers;" Edm. H. Miller, pp. 137; octavo; reprint of a series of practical articles in School of Mines Quarterly in convenient form; $1.50; D. Van Nostrand Co., 23 Murray St., New York City.

Obituary.

EDWARD WALLOWS, a California pioneer, aged 74 years, died at Dutch Flat, Cal., on the 5th inst.

GEO. BLAKE, formerly superintendent of the Star and O. K. mines in Tuolumne county, Cal., died at Silver City, N. M., recently.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING APRIL 5, 1904.

756,311.—PAPER BOX—F. R. Adams, S. F.
756,565.—WRENCH—T. H. Barry, Empire, Or.
756,774.—STAMP MILL—M. P. Boss, S. F.
756,211.—PRECIPITATING METALS—C. Butters, Berkeley, Cal.
756,582.—VALVE—M. J. Chaplin, Seattle, Wash.
756,584.—BOTTLE—Chase & Dole, S. F.
756,328.—RECOVERY OF PRECIOUS METALS—S. B. Christy, Berkeley, Cal.
756,596.—CORSET SPRING—E. M. Dhale, Oakland, Cal.
756,780.—BOWLING ALLEY—E. F. Dreger, Oakland, Cal.
756,350.—HOSE MENDER—F. A. Garhutt, Los Angeles, Cal.
756,620.—NUT LOCK—W. Ghiglieri, Stockton, Cal.
756,627.—INSULATOR—Hanson & Lamhert, Davenport, Wash.
756,360.—MOWING MACHINE—Harrah & Flint, Pendleton, Or.
756,362.—ROTARY ENGINE—R. Hazelrigg, Cottage Grove, Or.
756,370.—ANIMAL EXTERMINATOR—G. R. Jack, Lockeford, Cal.
756,371.—HOUSE—W. C. James, Cucamonga, Cal.
756,508.—TELEPHONE—G. Konigstein, S. F.
756,385.—MOP HOLDER—J. C. Look, Tudor, Cal.
756,514.—GAME—G. W. Maxwell, S. F.
756,701.—CLIP BAND FASTENER—C. L. Pope, Ely, Nev.
756,529.—GAS COMPRESSOR—S. S. Rose, Amador, Cal.
756,531.—SPRING KNOTTING MACHINE—J. H. Ross, S. F.
756,532.—SPRING DOWEL MACHINE—J. H. Ross, S. F.
756,804.—TOILET PAPER HOLDER—A. E. Sexton, Los Angeles, Cal.
756,425.—SAW GAUGE—W. Stephens, Montesano, Wash.
756,438.—BUOY—W. L. Uhlenhart, Portland, Or.
756,548.—DRAPER—J. C. White, Marysville, Cal.
756,758.—DISPLAY STAND—W. G. Winans, Spokane, Wash.
756,765.—FEEDING DEVICE—Z. Xevers, Santa Cruz, Cal.

Notices of Recent Patents.

Among the patents recently ohtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

GAS COMPRESSORS FOR ICE MACHINES.—No. 756,529. April 5, 1904. S. S. Rose, Amador City, Cal. The object of this invention is to provide a compressor acting upon a freezing medium, as ammonia gas, which will he simple of construction, whose parts are easily accessihle, in which the cooler gas is delivered directly into the cylinder from the coils without coming in contact with or heing heated hy the running gear of the compressor, and in which the chances are ohviated of any admixture of gas with the oil in which the gear in such machines usually runs.

SPRING KNOTTING MACHINE.—No. 756,531. April 5, 1904. J. H. Ross, San Francisco, Cal. Assigned to American Steel & Wire Co. of San Francisco, Cal., a corporation. The object of this invention is to provide a machine for automatically tying or "knotting," as it is called, the end of a conical spring after it comes from the colling machine; such springs heing used as coil furniture springs.

TELEPHONE ATTACHMENTS.—No. 756,508. April 5, 1904. Gahor Konigstein of San Francisco, Cal. One-half assigned to Joseph Silverman of San Francisco, Cal. This invention relates especially to desk telephones. It consists in the comhination, with the vertical post or standard, of a desk telephone having a transmitter adjustahly hinged to its top, of a receiver, and an arm upon which the receiver is carried, said arm heing adjustahle with relation to the post or standard and the transmitter, so as to he supported in proper relation with the ear of the user. In conjunction with these parts are the hook upon which the receiver is ordinarily suspended and hy which an open circuit is normally maintained, connections hetween said hook and a vertically guiding slidable rod, an arm or hand piece hy which the hook is raised and the circuit closed preparatory to conversation and a device hy which the parts may be maintained.

Latest Market Reports.

San Francisco, April 15, 1904.

METALS.

Silver.—Per oz., Troy: London, 24⅛d (standard ounce, 925 fine); New York, bar silver, 53¾c, refined (1000 fine): San Francisco, 53¾c; Mexican dollars, 43½ San Francisco, 43c New York.

Copper. — New York: Standard, $13.25; Lake, 1 to 3 casks, $13.50: Electrolytic, 1 to 3 casks, $13.12½; Casting, 1 to 3 casks, $12.87½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £57 15s spot per ton.

Lead. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¼c 1000 to 4000 lbs.; pipo 6½, sheet 7, bar 5¾c; pig, $4.85. London: £12 17s 6d ℔ long ton.

Spelter.—New York, $5.30; St. Louis, $5.00; London, £22 5s ℔ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

Tin.—New York, pig, $27.87½@28.12½; San Francisco, ton lots, 30c: 500 lbs., 30½c; 200 lbs., 31c; less, 32c; bar tin, ℔ lb., 32¼@35c. London, £127 spot.

Platinum. — San Francisco, crude, $18.00 ℔ oz.; New York, ingot, $19.00 ℔ Troy oz. Platinum ware, 75 @ 82c ℔ gram.

Quicksilver. — New York, $45.50@46.50, large lots; London, £8 5s 0d; San Francisco, local, $43@44 ℔ flask of 76½ lbs.; Denver, $46.00. Export, $43.00@43.50.

Babbitt Metal.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; oxtra, 17½c; gonuine, 31½c; Eclipse, 35c.

Solder. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

Zinc.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

Nickel.—New York, 50@60c ℔ lb.; ton lots, 40@47c.

Aluminum.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

STRUCTURAL MATERIALS.

Iron.—Pittsburg, Bessemer pig, $14.20 @14.35; gray forge, $13.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

Steel. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ℔ lb.

Lime.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

GENERAL SUPPLIES.

Antimony. — New York, Cookson's, 7c; Hallett's, 6½c; San Francisco, 1000-lb. lots, 8c; 300@500-lbs., 8½c; 100-lb. lots, 10½c.

Powder.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

Caps.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

Fuse. —Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tapo, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

Candles.—Granite 6s, 16 oz., 40s., 11½c ℔ set; 14 oz., 40s., 10c.

Chemicals. — Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphito of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.20@1.40 ℔ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrato of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdored sulphur, 2@3c; flour sulphur, French, 3½@3¾c; alum, $2.00@2.25; California rofined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75: sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

Bone Ash.—Extra No. 1, 5@6c ℔ lb. No. 1, 4@5c.

Coal. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.00; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

Oils.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 47c; cs., 52c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c: 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, puro, bbl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

White Lead.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

Red Lead.—500 lbs. and over at one purchase, ℔ lb., 7c; less than 500 lbs., 7¼c.

Litharge.—Pure, in 25-lb. bags, 8@9c ℔ lb.

Borax.—Concentrated, 6@7c ℔ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

Manganese.—Pure, ℔ lb., 60c.

Sodium.—Metal, ℔ lb., $1.00.

Bismuth.—Subnitrate, ℔ lb., $2.00.

Mercury.—Bichloride, ℔ lb., 77c.

Molybdenum.—$2.00 ℔ lb.

Chromium.—90% and over, ℔ lb., $1.00.

Phosphorus.—American, ℔ lb., 75c.

Silver.—Chloride, ℔ oz., 90c@$1.00: nitrate, 55c.

Aluminum.—No. 1., 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

Uranium.—Oxide, ℔ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

BUSINESS OPPORTUNITIES

PARTNER WANTED TO INVEST $10,000

in operating copper-gold mine on Vancouver Island. Will make extensive stock proposition or pay to work. J. H. BROWNLEE, Lick House, S. F., Cal.

"THE ACME OF PERFECTION" is the verdict given our Burt Exhaust Head by the Zeeland Milling Co., Zealand, Mich., and hundreds of others. The Burt Exhaust Head will save you a large expense bill for repairs on your walls and roof, damaged by steam from the exhaust pipe and it will deaden the disagreeable noise made by the exhaust. The Burt Exhaust Head will give perfect satisfaction. Order to-day, stating size of pipe; cost you nothing if the head is unsatisfactory.

THE BURT MFG. CO.,
Largest Mfrs. Oil Filters in the World.
221 Main St., Akron, Ohio, U. S. A.
Supplied also by Engine Builders, Dealers and Power Contractors.

SITUATIONS WANTED.

Assayer and cyanide mill man desires position with established company. Address "Assayer," care Mining and Scientific Press.

Cyanide chemist and assayer, at present engaged, who has successfully superintended cyanide plants, wishes to communicate with some company about to make provision for the treatment of slimes and which is not satisfied with any of the systems used at present. Address "Slimes," care of this office.

Experienced assayer and chemist desires change of position by May 1st, preferably with smelting company. At present employed in Mexico. Best of references. Address E.T.A., care this office.

Experienced superintendent, engineer, Metallurgist; technically and liberally educated; 15 years handling men and machinery of smelters, mills and mines. See testimonials. Address Prof. Stickney, Mountain View, Cal.

Expert assayer with practical working knowledge of cyanide and chlorination processes, desires situation. Correspondence solicited. Best of references. Address B., care of this office.

Man with twenty years' experience quarrying sandstone and slate would like to take a quarry on contract. Address G. D., care of this office.

Mill and cyanide superintendent wants position. Thoroughly understands milling of gold ores and the cyaniding of same. Good assayer. Address D. A., this office.

Mine superintendent is open to engagement with a live company. Thoroughly understands his business. Address B. R., this office.

Miner with fifteen years' experience and fair knowledge of Spanish wishes employment as shift boss in some Mexican mine. Address N. B , this office.

Superintendent of construction, up to date on design and erection of mining and smelting equipment, open for immediate engagement. Address L.A.H., Mining and Scientific Press.

Superintendent, fully competent and experienced, desires position. Assayer, chemist, surveyor and mill man. Address J. C., care of this office.

HELP WANTED.

Wanted, by a first-class mining company, a good energetic all around machinist as repair man, to take charge of gyratory crusher and general mill repairs. None but competent, sober men need apply. Address M. R., this office.

Wanted—Competent assayer who also understands bookkeeping. Address R., care of Mining and Scientific Press.

"The truth, the whole truth and nothing but the truth"

PATENTS

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, our Washington branch which tends *exclusively* to our business before the Patent Office, intimate acquaintance with the subjects of inventions in our own community, and our most extensive reference library, containing official American reports since 1790, with full copies of U. S. Patents since 1872. All worthy inventions patented through DEWEY, STRONG & CO.'S Patent Agency will have the benefit of a description in the *Mining and Scientific Press*. We transact every branch of patent business, and obtain patents in all countries which grant protection to inventors. The large majority of U. S. and foreign patents issued to inventors on the Pacific Coast have been obtained through our agency. We are conservative and counsel preliminary examinations in cases of doubtful novelty. Guide to inventors sent on request.

Whole No. 2283.—VOLUME LXXXVIII. Number 17. SAN FRANCISCO, CAL., SATURDAY, APRIL 23, 1904. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Spheroidal Weathering.

The accompanying engraving illustrates a phenomenon often observed in regions of massive eruptive or intrusive rocks. On first sight one might think the numerous boulders were the result of stream erosion and deposited by such. They, however, are "in situ" and rest on large masses of the same material, and are the result of spheroidal weathering. This property is particularly exhibited by some granites (the case illustrated is of granodiorite at Nevada City, Cal.), but it is also observed in greenstone, various porphyries, andesite, etc. When the more or less angular fragments of the rock are attacked by atmospheric or other decomposing agencies, the corners are first softened and removed or replaced, and the action continuing inward develops a rounded exterior if the boulder is on the surface so that the decomposition products can fall away from the main portion. If, however, the altered portion remains in place, as when the rock fragments are below the surface, on cutting through it a succession of concentric shells are seen around an unaltered core. Sometimes these shells are replaced by other minerals, occasionally ore bearing as in the Bassick mine at Rosita, Custer county, Colo., and described by S. F. Emmons, Trans. Amer. Inst. Min. Engrs., Vol. XVI, p. 833. Where this phenomenon occurs at depth, due to the chemical action of circulating waters, it is known as concentric decomposition. Concerning the occurrence at the Bassick mine, Mr. Emmons says: "The deposit of the Bassick mine is a nearly vertical chimney. It occurs in an andesitic breccia, composed of angular fragments of various sizes and forms cemented together by material of essentially the same composition as the fragments, the cementing material being more readily attackable than the fragments, for the ore has replaced it, forming concentric layers around the latter, whose angles have become rounded during the process of deposition. Here the fragments were original and were necessarily produced by dynamic movements, which probably resulted in a simple fracturing of the rock without much displacement."

In the cut may be seen fragments and shells which have dropped off from the boulders, and also disintegrated, incoherent material. On the left is a boulder resting on a sort of pinnacle or cone-shaped mound, the decomposed products having fallen away from underneath of a large portion of it. Probably the fine material was partly washed away by rain waters. At Nevada City, the surface of the main masses of the grauo-diorite, often many feet across, have a dome-shaped appearance, showing that the action goes on in the main mass as well as the fragmental portions.

There are hundreds of granite boulders in the neighborhood of Prescott, Ariz., which have been produced in this manner, and at the Catoctin silver mine, 15 miles southwest of Prescott, the porphyry dike accompanying the vein shows a beautiful illustration of concentric decomposition. A similar condition may be observed in greenstone tuff near the German mine, El Dorado county, California.

Spheroidal Weathering of Grano-diorite at Nevada City, Cal.

In some instances where spheroidal weathering has occurred the phenomenon has been considered due to stream erosion, and miners have been led to prospect for placer in such deposits, in the belief that gold might be found. In the instance at the German mine above referred to gold was actually discovered, constituting a placer in fact, but the gold came from pockets which had been disintegrated a short distance above on the hillside, as evidenced by the rough and crystal form of the pieces of gold found. There was no evidence whatever of a stream having ever beeu there.

In some way mines and courts seem to have something in common, but it is not always questions of mining law that involves mines and mine owners in litigation. Occasionally it is found necessary to appeal to the courts to adjust other questions than those bearing upon such abstruse problems as those connected with the extra-lateral right. And in these cases in which the technicalities of mining law find no place, the rulings of the court are sometimes quite as surprising as they are occasionally in the more intricate cases. An instance occurred not long since in Australia where a man was accused of stealing a bucket of rich telluride ore found at his back door. The defendant denied the charge and said it was his opinion that some personal enemy had placed the ore where it was found to make a case against him. The court admitted the plausibility of this defense and declared defendant not guilty. Upon acquittal the former defendant applied for an order of court demanding that the ore in question be turned over to him and the order was accordingly made, there apparently being no other claimant who could legally establish ownership to the ore. This is an instance in which the law gives a man that which he cannot rightfully claim.

THE difficulties of obtaining sufficient unskilled laborers for the mines of the Transvaal appear to be increasing with the spread of a disease which is locally called the plague. It affects Asiatics, natives and white men alike. Numerous deaths have occurred among the several nationalities. Petitions for and against the free importation of Chinese coolies continue to be circulated among the mines of the Rand. Mine managers and mine officers generally, as well as the white men who are employed, sign "for" the Chinese, and the unemployed sign "against" them. It is not improbable, however, that the experiment of Chinese in the mines will be tried, as the General Government sanctions the scheme.

THE department of mines of Queensland, Australia, recently decided that all official mining returns, monthly aud annual, shall be made in fiue ounces, which is a good idea, as by its use all who are interested may figure the value in whatever coinage they please. In Western Australia a similar rule has been made, but unfortunately the officials of the Goverument have complicated matters by requiring that these returus shall be per ton of 2240 pounds, which is indeed a step backward. There should always be an endeavor to simplify public documents and reports, and in such a decimal system is desirable, but if the metric system is not popular, the ton of 2000 pounds is standard and easier of computation than the long ton of 2240 pounds.

THE Vindicator mine at Cripple Creek, Colo., furnishes an interesting object lesson on the distribution of ore bodies and the uncertainty which always exists in ground not thoroughly prospected. The mine has been vigorously and successfully operated to a depth of 1200 feet and a large amount of valuable ore removed. Last August the mine was closed at the beginning of the strike and the pumps removed from the bottom of the mine. In a few weeks the water rose in the workings to the water line about the 1000-foot level. Since resuming work the company has been exploring the ground above the drainage level and has found several large and rich shoots of ore in the undeveloped territory, which, in the haste to reach depth, were passed by. These new ore bodies will now permit a large output from ground previously considered of uncertain value. It indicates the possibilities that lie in other properties of the district, at points above drainage level. This is not the first experience of the kind in Cripple Creek district, and it should be suggestive of the great possibilities which lie near the surface, at least above the 1000-foot level. In the haste to get great depth much promising territory remains undeveloped.

The One Mine Camp.

For some reason there is found among many miners a prejudice against a "one-mine camp." The camp where there is but one mine is looked upon by some men with suspicion, and to be avoided, ofttimes by men who should have better aud broader ideas. It should be remembered that, in all probability, if it were not for that one mine there would be no camp there at all. The arguments against the one-mine camp are: The miners are compelled to board at the company's boarding house and to patronize the company's store. They must buy all they require—clothing, boots, shoes, tobacco, etc., at this one store. In some instances it is claimed the men innocently patronize the company's store and at the end of the month find they have nothing coming, or worse still are in debt to the company. This does seem to be unfair and unnecessary, but does analysis of the situation show this to be a fact? In the first place, mining companies as a rule are not organized and run for the purpose of building up a village or town about the works. The primary object of the company is to make money upon the capital invested, and this the greater number strive to do legitimately. When an isolated mine is opened and worked a new village springs up about it, and if there be but one company operating there the management must do something to accommodate the miners. At no mine are the men all single or all married. They who are single must have a place to sleep. and as the greater number prefer boarding to "batching," necessarily the company must supply these wants. This means the investment of several thousand dollars more in bunk houses, and boarding house and their equipment. It is only just that the boarding house should not be run at a loss, consequently the management must make a rule that all employes shall patronize the boarding house. Often exception is made in the case of married men, with whom the matter is optional. Where the proposition is left to the miners, the boarding house becomes a "nightmare" to the manager. One week there will be more than can be accommodated, the next there will be less than half the former number, and the arrangement cannot always be regulated to meet the requirements of the miners. Of necessity the company insists on the men making use of the accommodations afforded, as this is a portion of the organization, though only an incidental part. As to the company store, of which there is so much said in its disparagement, that too is usually a necessity when the mine is remote from the nearest town, and hundreds of men will candidly admit that the store is often a great convenience. Prices are usually higher than in towns more easy of access, but it should be remembered that there are additioual freight charges. Mines are not philanthropic institutions couducted for the benefit of a community which may spring up about it, but are operated for the purpose of making money, the same as any other industrial enterprise.

The miuer who at the end of the month finds himself in debt to the company would in many cases find himself broke at the end of each month in cities like Cripple Creek, Leadville, or Butte.

There are places where the company boarding house and the company store are "made to pay," and the men do not receive the treatment or fair play they deserve, but good workmen will not usually remain in such a camp longer than necessary to get away. The company which treats its men with the greatest fairness, pays the going wages, supplies good food and comfortable accommodations, and runs its store on honest business principles will be found to have the best men obtainable in the country, for good men seek such places and are able to hold them against inferior workmen. It pays the company to give men fair treatment and to supply them with good accommodations, for the men in return are both able and willing to respond with more and better work. It pays to treat men well, even at a one-mine camp.

Cyanide Poisoning.

The use of cyanide of potassium in the treatment of gold and silver ores has spread throughout the world within the past twelve years. Twenty years ago the cyanide process was commercially unknown in the treatment of ores. Its first large application to the extraction of gold from its ores was made in New Zealand in 1888. Its possibilities were at once realized, and other cyanide plants were built. Gradually they extended and increased in number—slowly at first—until the chemistry of the process was better understood, and later the construction of cyanide plants became as common as the building of stamp mills or smelters. There are hundreds of plants treating from less than 5 tons daily to those which handle upwards of 2000 tons in twenty-four hours. Tons of cyanide of potassium are consumed in this branch of metallurgy annually, and notwithstanding the fact that cyanide is one of the most deadly chemicals known to science, and so prompt in its effects that medical aid is almost always futile, yet there have been very few cases of cyanide poisoning of men working in these plants reported, and until within the past few days no cases have been noted, or, at least, become generally known, wherein animals and fowls have died from drinking the waters of streams to which the discharge of cyanide works is tributary. The single exception is that of the Exposed Treasure cyanide mill in Kern county, California, where, a few miles from the village of Mojave, the mill of the Exposed Treasure Mining Co. is located in a canyon which is dry except when heavy rains fall. The water for the mill is pumped to it and the wash water, containing a very low percentage of cyanide of potassium, is allowed to run to waste down the desert canyon to the sand flats in the valley beyond, where it soon sinks from sight. A State deputy game warden was informed that all the game in that part of the county was being killed from drinking the deadly waters coming from the Exposed Treasure mill. The investigation is said to have shown that numerous doves were found lying along the banks or near the stream. At a distance of 3 miles from the mill it is said the sand in the tailings has settled and the water has become comparatively clear, and from that point onward until the water is absorbed by the desert sand the stream is lined with the bodies of dead birds, rabbits, and even cattle which have drank of the waters.

As previously stated, this is the first instance of importance of the kind ever reported, and the reason may probably be found in the fact that the canyon in which the Exposed Treasure mill is located docs not contain a living stream, and the water discharged from the mill is dangerous and even deadly, though containing a minimum of cyanide of potassium—for managers of cyanide mills do not permit strong solutions—0.25%—to escape if it can be helped, solutions of that strength being pumped back for reuse, but the water employed in washing out the pulp from the treatment vats must flow away, and if impounded it would be useless unless it be discharged into a reservoir of so large a superficial area that the evaporation would equal the amount of water running from the mill into the basin. It would seem, however, that possibly the amount of water flowing down the canyon might be lessened by pumping it back from a settling reservoir, thus reducing the quantity of water required from the original source, if this has not already been doue. If, as in most other places, the canyon contained a living stream, the deadly solution would probably become sufficiently reduced in strength to be innocuous, but as nature has not generally provided living streams iu the desert mountains it remains for the company to render the situation as harmless as possible, by one of the methods suggested or by fencing the stream along that portion known to be dangerous.

CONCENTRATES.

AN analysis of coal should show the percentages of: Water, volatile carbon, fixed carbon, ash and sulphur.

✤✤✤✤

TO FILL a tank having a capacity of 100 cubic feet at a pressuro of 200 pounds per square inch would require 1400 cubic feet of freo air.

✤✤✤✤

"FIVE VOLTS DROP" on a machino means that that voltage is used in the machine itself, and must be provided for. To amalgamate a zinc in a battery cell, clean the zinc with acid and coat it with mercury.

✤✤✤✤

WHERE the land in question has not been patonted, the discovery of mineral thereon would except it from the State or federal grant to the railway company, the latter in that case having no jurisdiction over it.

✤✤✤✤

AN ordinary charge in pyritic smelting would be about as follows: Pyrites, 15%; quartz ores, 45% (containing lime and pyrites); lime ores, 20%; low grade matte, 10%; slag, 5%; coke, 3% to 5%; from 1% to 2% charcoal; the charge of fuel to be about 5% of the total.

✤✤✤✤

AN undershot water wheel to develop 2 H. P. in a 6-mile-an-hour current tho area of each bucket should be 4 feet, with an immersion of 1¾ feet above the periphery; the wheel should be 8 feot diameter; have twelve buckets and make about ten revolutions per minute.

✤✤✤✤

EMERY is a mechanical admixture of corundum and magnetite or hematite. It is the presence of corundum in the emery that gives to it its abrasive qualities and makes it of commercial value. The abrasive efficiency of emeries varies according to the percentage of corundum they contain.

✤✤✤✤

TO CONVERT Centigrade thermometer readings to Fahrenheit, multiply by 9, divide by 5 and add 32. To convert Fahrenheit readings to Centigrade, subtract 32, multiply by 5 and divide by 9. On a Centigrade thermometer 0° is freezing point of water and 100° boiling point; while on a Fahrenheit thermometer the corresponding points are 32° and 212°.

✤✤✤✤

A "TENTADURA" is defined as a sort of assay made in a horn spoon, in an earthen saucer, in a wide and sballow vessel of any kind, for the purpose of ascertaining the amount of amalgam present in a sample of argentiferous mud from an amalgamating patio; any assay made by washing, so as to concentrate the metallic portions of any mineral and to cause the earthy portions to be floated off.

✤✤✤✤

THERE has been no change in California law and there is no such thing as "non-assessable stock" under the laws of that State. The stock in a California corporation of any kind, mining or any other business, is subject to assessments, and stockholders are responsible for the amount of assessment legally levied upon corporate stock held by them, any agreement or statement to the contrary notwithstanding.

✤✤✤✤

THE "critical temperature" of a gas is that temperature above which, no matter how great pressure it may be under, it will not condense and become a liquid—i. e., when above the critical temperature no amount of pressure can liquefy the gas. For hydrogen this temperature is 242° below 0° C., while for carbon dioxide (CO_2) and some others it is above the ordinary temperature, so that pressure alone will liquefy them.

✤✤✤✤

GENERALLY there are two ways of igniting the explosive mixture of gas and air in gas engines—one by use of an incandescent tube or wire; the other by the electric spark. The latter is considered preferable. There are two methods of electric lighting—that simply using a spark coil, where the spark of the electric current is utilized, and that employing a Ruhmkorff coil or open core transformer. The latter method often gives better results.

✤✤✤✤

IT is probable that zinc in slag from a lead blast furnace exists chiefly as silicate, a small percentage possibly as sulphide, partly free and partly combined with other sulphides. Lead occurs as metal, as silicate and as sulphide. Oxidation of the sulphide produces some sulphate, which gives rise to the white fume so commonly noticed. Silver exists in the slag as a constituent of the entrained matte. Silver can not exist in slag in the form of silicate.

✤✤✤✤

EYE BARS for bridge work were formerly made by hammering, but in doing so the metal crystallized and this proved detrimental to their strength. They are now pressed into shape by special machinery. The head of the bar is built up with plates of the proper size, care being taken to keep these apart so as to let the heat permeate the whole mass of metal. After it is heated into a semi-fluid or good welding heat the whole is placed under the press, and the pressure welds the whole into a solid piece, at the same time facing it.

✤✤✤✤

IN the electric generating plant of the Bay Counties Power Co. at Colgate, Cal., the dynamos are direct-connected to impulse wheels that operate under a head of 700 feet. The three 2500-kilowatt dynamos are each mounted on a wheel shaft operating at 285 revolutions per minute: each of the four 1125-kilowatt dynamos is direct-driven by an impulso wheel at 400 revolutions per minuto. In such plants threo-phase machines are usually employed. High voltage is transmitted 143 miles between Colgate and Oakland, Cal.

IT has been and is the pleasure and the privilege of the publisher to receive warm encomiums and cordial endorsement of this journal from all parts of the world, and their receipt constitutes an ever present source of satisfaction. One of the strongest and at the same time one of the most unusually worded comes from an Idaho mining camp where all the concomitants of modern jurisprudence are not yet existent, but where the reputation of this journal is evidently appreciated. The writer says: "In the absence of a Bible we swear a witness on a file of the MINING AND SCIENTIFIC PRESS."

✤✤✤✤

A PIECE of timber 6x6 inches at one end and 18x18 inches at the other and 12 feet in length contains 156 feet board measure. The most logical way is first to find the cubic contents of the piece of timber, and, multiplying that by 12, changes it to board measure. The area of the large end is (in feet) 1.5x1.5, or 2.25 square feet; the area of the small end, .5x.5, or .25 square foot; the mean proportional is the square root of 2.25x.25, or .75 square foot. Adding these three gives 3.25 square feet. This volume multiplied by $\frac{1}{3}$ equals 13 cubic feet. That multiplied by 12 gives 156 feet board measure in the stick.

✤✤✤✤

AN applicant for a patent has the right to unite in one application claims for a process and claims for an apparatus where the inventions are related and dependent: an order of the primary examiner twice made denying that right and requiring a division between the claims for a process and those for an apparatus is equivalent to a rejection of the application, and entitles the applicant to an appeal to the board of examiners-in-chief under Section 4909 of the United States Revised Statutes. It was so held by the Supreme Court of the United States in the case of the United States ex rel. Steinmetz vs. Allen, Comm'r.

✤✤✤✤

EXPERIMENTS and experience in attempts to burn pulverized coal go far toward demonstrating that it is difficult to obtain combustion of such fuel with as small an amount of air per pound of fuel as can be obtained in the best practice with coal fired on an ordinary grate, and this has always tended to make the economy lower than with the usual method. Besides, the power required to operate the coal pulverizer and feeder has counted against the efficiency of the plant, as a whole, and there is usually some difficulty from the collection of ashes and unconsumed particles of coal in the back connections of the boilers.

✤✤✤✤

TO FIND the capacity of a duplex pump, multiply the area of the water end by the stroke; that will give the number of cubic inches of one side, per single stroke. Multiply that product by the number of strokes per minute and by 2. Then divide by 231, the number of cubic inches in a gallon, which will give theoretical capacity. Multiply that product by the efficiency to get the true capacity. Example: Find the capacity of a duplex pump with a diameter of 3½ inches, stroke 6 inches, number of strokes 75, efficiency 70. Operation: Area = 9.62 square inches × 6 inches = 57.72 × 75 = 43,290 × 2 = 86,580 ÷ 231 = 374.8 gallons; 374.8 × .70 = 264.36 gallons, true capacity.

✤✤✤✤

ANY manufacturer will send a catalogue or trade publication that he issues to any address designated, in the idea that the asker wants what is therein described and is a possible customer. The privilege certainly is abused, and many manufacturers seriously contemplate charging a nominal sum for the catalogues that are expensive, with a view to checking indiscriminate and unprofitable demand from those prompted only by curiosity. Meanwhile our inquirer need feel no hesitancy in writing for any catalogue reviewed or noted on the usual page of each issue of this journal, or similarly in its contemporaries, though it were well to enclose a few cents in each case—say 6 or 8—for necessary postage thereon.

✤✤✤✤

A LARGE VARIETY of combinations of iron and carbon with tungsten, chromium, manganese, nickel, silicon or molybdenum characterize the special steels now on the market. Every maker furnishes, besides his regular carbon steel, a self-hardening steel, and an intermediate grade, which may be called a semi-self-hardening. The latter is capable of being hardened in water without cracking and is suited for extremely hard cutting. The self-hardening steels cannot be brought in contact with water while hot on account of the danger of cracking. Some of the milder grades rely on the assistance of an air blast after forging to give them the proper degree of hardness for their work, and are called "air hardening steels."

✤✤✤✤

GRAPHITE makes a good lubricant. A fine machine lubricant is made by taking 100 parts of mineral oil, 75 of linseed oil, 50 of rapeseed oil, 100 of spirits of turpentine, and 25 of lime slaked in five times its weight of water. The liquid thus obtained by slaking is boiled, and the linseed oil, the rape seed oil, the spirits of turpentine and the mineral oil are in succession added to it. Tho mixture is to be boiled for six or eight hours and used only when cold. Should it prove too hard it is because too much lime has been put in. To tell if the lubricant is pure put a sample of it, the size of a pea, in a glass of water. If it floats or only sinks very slowly the lubricant is pure; if it falls quickly to the bottom it has heavy substances mixed with it and is not fit for fine uses.

✤✤✤✤

A MINING ENGINEER can be too scientific as well as not scientific enough. No matter what the amount of "science" one may carry he must have commercial efficiency to make it count, and the business ond of any thing undertaken must at least be as well understood as the scientific or technical end of it. If a mine shaft is to be sunk or a mill built, the man that is putting up the money wants an engineer that can not only do the work well, but also do it economically, and so that it can be made to pay. The man furnishing the money is usually not so much interested in how the shaft or mill looks as a finished and fine product, as in the profits resulting from the operation of the shaft or mill. The most successful engineers are men in whom the commercial instinct is well developed.

✤✤✤✤

THE new department in the United States Cabinet of Commerce and Labor when first prepared had a provision in it for the establishment of a bureau of mines and mining, and the idea at the time was to transfer the Geological Survey from the Interior Departmont to the new department. Upon its passage by Congress, however, that was all stricken out, and the bill as passed simply enumerates mines and mining as one of the industries to be fostered by the new department. The only apparent good that that can do would seem to be that in the preparation of statistics the magnitude of the mining industry as a great national matter will finally become so apparent to even the federal legislators that the long deferred cabinet department of mines and mining will be advanced on the calendar of statesmanship.

✤✤✤✤

REGARDING the old slag dumps at Eureka, Nev., they could be undoubtedly utilized, as suggested by our correspondent, in the manufacture of Portland cement, but transportation would interfere with the commercial side of tbe idea. Any big "deposit" or accumulation of furnace slag, the same as at Eureka, is susceptible of similar disposition. But the materials for manufacture of Portland cement are so plentiful, cheap and widespread that it is doubtful if the Eureka slag dumps, though rich in lime, iron and manganese, which take the place of silicate of alumina, could be brought in successful competition with more centrally located sources of supply. "Concentrates" suggests, however, that a more probable source of profit would suggest itself in such cases as that cited by our Eureka correspondent in making what is sometimes called "mineral wool" out of those slag dumps—blowing it into long, fine strings of substance having sale in a variety of ways in industrial arts.

✤✤✤✤

REGARDING the assaying or analyzing of coal to determine its coking powers, in case of any doubt, and in order to determine the power of the coke to withstand a crushing burden, tbe coking of a large quantity of coal in heaps would be advisable, rather than to risk the erection of costly coke ovens before it is known whether the coal will or will not coke. As the amount and composition of the ash in a coke is of the first importance, analysis of smelter samples of large lots are preferable to grab samples, which may vary so much as to be worthless. The ordinary way of sampling coal for assaying is similar to that used in metal mines, viz., right across the whole coal vein. The ingredients bearing upon the commercial value of coke are the water, sulpbur, volatile combustible, ash and fixed carbon. Of these, the latter only is valuable, the first four vary to a greater or less extent and are detrimental. Ash should be as low as possible in a good coke. The volatile combustible would, if present at all in large quantities, cause the coke to shatter in a blast furnace. Sulphur in coke is due mainly to the presence of iron pyrites in the coal. While detrimental in iron smelting, it is not present in sufficient quantity to make much difference in lead, silver or copper-silver smelting. The constituent which cuts a real and considerable figure in many cokes is the ash, which throughout this west half of America is usually high. When the ash of a coal or coke is only such as would result from the condensation of the plant ash of the coal-bearing flora it should rarely exceed 6% in the coal or 10% in tbe coke. A lower ash than this is called normal, and in metallurgical work is considered self-fluxing. Where the ash exceeds this it is generally siliceous and may result from a failure to sort out the slate cleanly or from bone or sandy impurities in the coal at the time of its deposition. This sand or clay is highly siliceous and its presence in a coke makes it far less desirable to the smelters than a coke with a normal self-fluxing ash. An example will make this clear. Taking a normal coke with ash at 9% as a standard, a coke with 19% ash would have the excess of 10% mainly made up of sand or silica and clay or silicate of alumina. As ore of this class, which it replaces on the furnace, has to be heavily fluxed, and would be given about a $15 smelting charge, the 10% ash would cost the lead-silver smelters $1.50 per ton of coke, in addition to the fact that they are paying for 10% of dead weight instead of fuel. The furnaces would also work poorly with such a coke.

Ore Delivery From Stopes.

Written for the MINING AND SCIENTIFIC PRESS by E. L. LEFEVRE.

The economical disposal of ore after it is broken down in the stopes is a problem of great importance and frequently demands displays of higb technical knowledge from managers in order to bring the various items of timber cost, labor and repairs within a certain limit of cost per ton of ore, beyond which prudence demauds a halt. It is a matter of surprise, too, at the perfunctory way in which some managers give directions for mill hole coustruction at variance with all rules of economic mining. As soon as the ore body is opened up the problem of its economical handling at once becomes paramount, and while it is true that a haphazard selection of a method of ore delivery will, and frequently does, answer the purpose, yet instances of injudicious adoption of faulty systems are too common. The executive head of a mine, intent on producing results iu the best way at least cost, has a large field before him when he takes up the study of the timber problem of a big mine, located usually at a place where timber is a scarce article. The practical, expeditious and cheap delivery of ore may be placed at the head of the subdivisions of timbering and a uumber of otber tbings considered before a general scbeme of mill hole construction is finally adopted. Size of the ore body, dip of the vein and character of the walls are the major items upon which to base a decision. Physical properties of ore, distance between levels viewed with reference to the probable wear of the timbers, proper spacing in order to facilitate shoveling, and an exact comparison of relative costs of the various systems are other things that influence the adoption or rejection of a general plan of ore delivery.

There are six meritorious systems of mill hole construction in general use, and these, with slight modifications to fit individual cases, furnish a diversity of plans sufficient to meet the requirements of any kind of an ore body. These are:

1. The crib of tenoned mill timbers.
2. The stulled mill hole.
3. The stull and block mill hole.
4. The all-block mill hole.
5. The stoue-faced mill bole.
6. The lined, square-set mill hole.

The first and most generally used is the crib built of tenoned timbers of fixed pattern dimensions.

This form is to be recommended for all veins having rotten walls, where it is not necessary to use the square set and where the stopes are filled with waste, as it furnishes the cheapest and most practical method of sustaining bad ground and affording an outlet for ore at the same time. It is well to state that, uo matter how great the dip of the vein up to that angle where the ore ceases to mechanically deliver into the hopper, the cribbed mill hole is by far the best sustainer of rotten ground we have, where a filled stope is used.

A number of things are to be cousidered even after physical conditions suggest the crib form of construction. The distance between levels, amount of ore, character and size of broken ore and average dip of vein are all determining factors in deciding upon the size and quality of timbers used. For example, it would be injudicious and wasteful to build a mill hole 3 feet in the clear for a narrow vein with levels 100 feet apart, unless the dip was excessive and tbe ore wet enough to block the hole by sticking to the sides. Not only would the timber cost be excessive, but a large unnecessary expense would be incurred in shooting out the walls in order to secure the space to properly set the timbers. On the other hand, I have known levels to be run 400 feet apart, using 3-foot mill holes spaced 60 feet apart. The dip of tbe vein was slight and free from abrupt variation, with a stoping width averaging 5 feet and fairly stable walls. In this particular instance timber was an expensive item, and the atmospheric conditions were such that two years represented the life of a first quality drift set. A careful scrutiny of the expeuse items convinced the management that it was cheaper to line the mill holes with first class 2-inch plank than to stand the staggering cost of drift timbers for intermediate levels. The mill timbers were sawed in a mill, thus furnishing a good face for the plank lining. The mill holes were raised 50 feet, then lined; a second 50 feet was added, lined, and the first lining repaired. By the time the third 50 feet was up the first was usually ready for relining. At places where the vein deflected from normal dip, exposing the timbers unduly, a double lining was put on when the hole was built. While this was an exceptional case, nevertheless it is a striking illustration of the possibilities of mill hole construction with cribbed timbers on a vein with a slight dip. Where the delivery distance is short, and spruce or other tough timber expensive, balsam fir or "quaking aspen" may be used with perfect safety, if the stopes are not to be withdrawn at some indefiuite time in the futurc. In that case first class timber is to be recommended, as the extra expense is more thau counterbalanced by the increased durability.

In framing mill-hole timbers patterus with varyiug tenon widths are used, and care should be taken that tbe tenons are of exact size, thus insuring a perfect fit and obviating trimming in the stope. The shoulder should not be less than 2 inches, and in holes having much dip more is advisable. The use of nails at the joints is a pernicious practice to cover up slovenly framing which may prove expensive in case it is necessary to replace timbers. Abrupt bends in the crib should by all means be avoided. An intelligent observance of the general contour of the vein vertically will show where a shot or two into the wall is advisable to avoid these and conserve the timbers at that point. It is better to line mill holes with 2-inch plank when first built at those places where falling ore strikes, for two reasons: First, the destructive effect of a falling mass of ore is much less when the fiber of the wood is parallel with the line of descent; and, second, the cost of replacing a timber cut in two would pay for several linings. Exact comparison will establish the fact that first-class 2-inch plank is by far the best material for lining mill holes. "T" rails and boiler plate are expensive fads that never fail to bring disaster and annoyance with their use. The reason for this is plain, as a lump of heavy ore dropping on a rivet head or track spike held tightly against a metallic face will snap off unless made of an unreasonable size and strength. The use of this form of lining tends also to take away one of the chief virtues of the crib—its mobility or the facility with which it may be bent. Where cribbed mill holes are to be kept filled or partly filled, they should be made large enough to prevent "hanging up" and carefully lined as built. The stulled mill hole is admissible in veins of auy size up to the point where the timbers become too cumbrous to handle, presupposing that the walls are stable, and are in general use on those veins of appropriate size where the stopes are to be filled with the broken ore reserves. It is a very expensive method of timbering, as the labor expense entailed in cutting the seats or hitches and properly setting the stulls is frequently prohibitive. As before stated, points like these should be carefully gone over before the final adoption of this system. Stulled mill holes are usually made 5 feet from ceuters of stulls, with retaining faces of split lagging and a 2-inch plank or slab liuing. It will be readily seen tbat it is desirable to have the hanging wall hitch cut, so that the upper and lower angles made by the stull and wall are 100° and 80° respectively. It is false economy to use stulled holes without lining, as the cost of repairing or replacing timbers cut by falling ore is very great and far exceeds the cost of a plank protection from the time it is put into use.

The third class, or stull and block system, is really a composite of the second and fourth forms of construction, aud furnishes a very durable form of mill hole without entailing a big lumber bill for lining. On tbe other hand, the amount of timber required renders its use unwise in many places. The adoption of this form of construction is therefore restricted to those mines where lumber is dear and timber cheap, and to those veins where the physical conditions are propitious. Its adoption is not to be recommended where the stoping width exceeds 5 feet unless exceptionally favorable conditions exist. A great saving in this system over the stulled form is the absence of a labor bill for cutting hitches which frequently amounts to a large sum. The writer is personally cognizant of several instances where the cost of hitch cutting amounts to $3 per linear foot of mill hole. The stull-and-block hole is constructed by first tightly wedging a stull in place between the walls, then filling in behind the stull with fine stuff level with the top. On top of this foundation and projecting over the stull 3 to 6 inches a course of blocks is laid, theu another stull, more fine stuff, then blocks, and so on. The distance which the blocks project over the stulls depends upon the size of the blocks and durability of the timber, as well as tbe probable wear to which the timber is likely to undergo without endangering the stability of the hole, for it must be understood that the block-and-stull mill hole is built to last the life of the stope without repairing. It can be repaired, of course, but it is slow, tedious work. The timbers used as blocking should be cut not less than 2 feet long and carefully graded as to diameter when laying. In this system of construction all the refuse timber of a mine can be utilized to advantage. Where this method is employed on small veius of rich ore, and where more or less waste rock must be moved from the stope in order to secure working space, it is uecessary to clean the hole down after using it for ore, as a surprisingly large amount will hang on the projecting blocks. For this reason it is well to have the projection as little as is compatible with safety. Yet if the stopes are properly handled this expense of dressing down should amount to practically nothing, as the miner can make the trip down, using a rope to prevent accidents, in a short time.

The fourth, or all block system, presents commendable features that makes it by far the most desirable one in certain places where the cost of timber of proper size is not too great. It is true that it costs a lot to build a mill bole 2 feet square with three sides composed of first-class timbers 18 incbes to 2 feet long. Yet, in cases where the vein is large and the ore hard and heavy, with an extreme delivery distance, in the long run it is ecouomical to build the block mill hole. The judgmeut of a foreman will tell him whether the foot wall is sound enough to be used for the principal wearing side of the hole. If it isn't don't build a block hole. There are a few points to remember, though, in order to secure satisfactory results from the heavy initial expense. The timbers should be sound and, if possible, air dried; they should be of sufficient length to remain in place in spite of the natural wear and strain incidental to hard usage; they should be laid by a thoroughly capable, conscieutious workman, and the orifice should be large enough to permit the passage of a man's body easily in case the ore hangs up, or a job of repairing presents itself. The straighter the line of ascent the greater the life of the mill hole, hence it pays to trim the foot wall to a reasonable extent to secure this evenness. A block mill hole properly constructed will last a long time subjected to the hardest usage unless some mucker tries to avoid breaking large lumps of ore and blocks the bole. The resulting necessity of shooting out the obstruction with dynamite or hoisting it out with a windlass should result in two things: Firing the culprit and seeing that a minimum charge of powder is used if shot. Repairing a powder shattered block mill hole is one of the slowest, most disagreeable and expensive tasks a mine timberman has. Besides, the patched place rarely holds when subjected to hard pounding.

The fifth, or rock faced mill hole, is one made feasible only in rare instances where the miueral may adhere to either or both walls with a central or adjacent dike of tough, hard blocky rock not subject to atmospheric disintegration. Where such a physical condition exists very efficient and durable mill holes may be constructed by using the rock, tying the courses every 3 or 4 feet by laying a split lagging back a little from the edge of the rock face, and spiking a split lagging to each end of this cross piece, then filling the whole over with fine stuff. Tbis system of tying makes it possible to carry rock mill holes to great heights without the danger of losing the hole in case a cave starts, which would happen in the event a straight rock face was used.

The lined square set, or the use of a foot wall with three sides of a square set is an old standby that will never be supplanted where the square set system of timbering is in vogue.

In mines worked through tunnels, and where a number of levels are run above the tunnel, it is good policy to put up raises for ore and waste in the solid rock adjacent the vein, provided, of course, the country rock is sufficiently stable. Raising is a cheap form of excavation, and wheu once done in hard rock the expense stops for all time.

Cyaniding Sulphurets Direct.

To THE EDITOR:—I have read the very valuable contribution of Prof. Christy in the late issues of the MINING AND SCIENTIFIC PRESS regarding the treatment of concentrates and the detrimental effect of metallic iron on the extractions, as well as on the consumption of cyanide, and this remiuded me of some experiments made several years ago that coufirm his conclusions very decidedly. Am sending you herewith the details of one experiment.

I had been making many tests by agitation in an old iron cleanup pan and was very much surprised at the extremely poor results obtained, and after considerable striving for the solution of the problem I concluded they might be due to the iron, and therefore put up a wooden agitator and ran it alongside of the iron one under precisely the same conditions. I was simply astonished at the results, which clearly showed that extractions were not only greater in the case of the wooden tank, but that an actual precipitation occurred in the iron one. The material worked on (the Bullionville slimes tailings) had been treated by pan amalgamation two or three times and contained, beside about 10% lead and a little copper, considerable acid salts that were added during the amalgamation treatment. The muller in the iron tank ground slightly on the bottom and some metallic iron doubtless got in the sludge in this way.

After discovering the very bad effect of the iron on the Bullionville material I took the same tanks to Pioche, Nev. (an adjoining mining camp, where we were about to treat the ore from the Yuba mine by agitation leaching), to determine if the same bad effects would be noticeable on the Yuba ore. Tests were conducted side by side under precisely the same conditions with the result that the wooden agitator extracted just 20% more values than the iron agitator did in eight hours. Therefore, in constructing the Yuba mill, wooden agitators were installed and no more iron than was absolutely necessary was used in the agitators. The Yuba ore contained 3% lead, mostly in the form of carbonate, and about 85% of the silver and gold was extracted after concentration, with a consumption of about one pound per ton of cyanide. So it could not be considered a very "base" ore.

Following is a summary of the agitation cyanide tests on Bullionville slimes made in wood and iron agitators at Bullionville, Nev., August 15, 1897:

The following conditions were the same in both cases: The iron agitator used was an all iron cleanup pan, while the wood tank was composed entirely of wood; thirty-five pounds of ore to sixty-five pounds of water; twenty-five pounds of lime added per ton of ore and agitated one hour. Then cyanide was

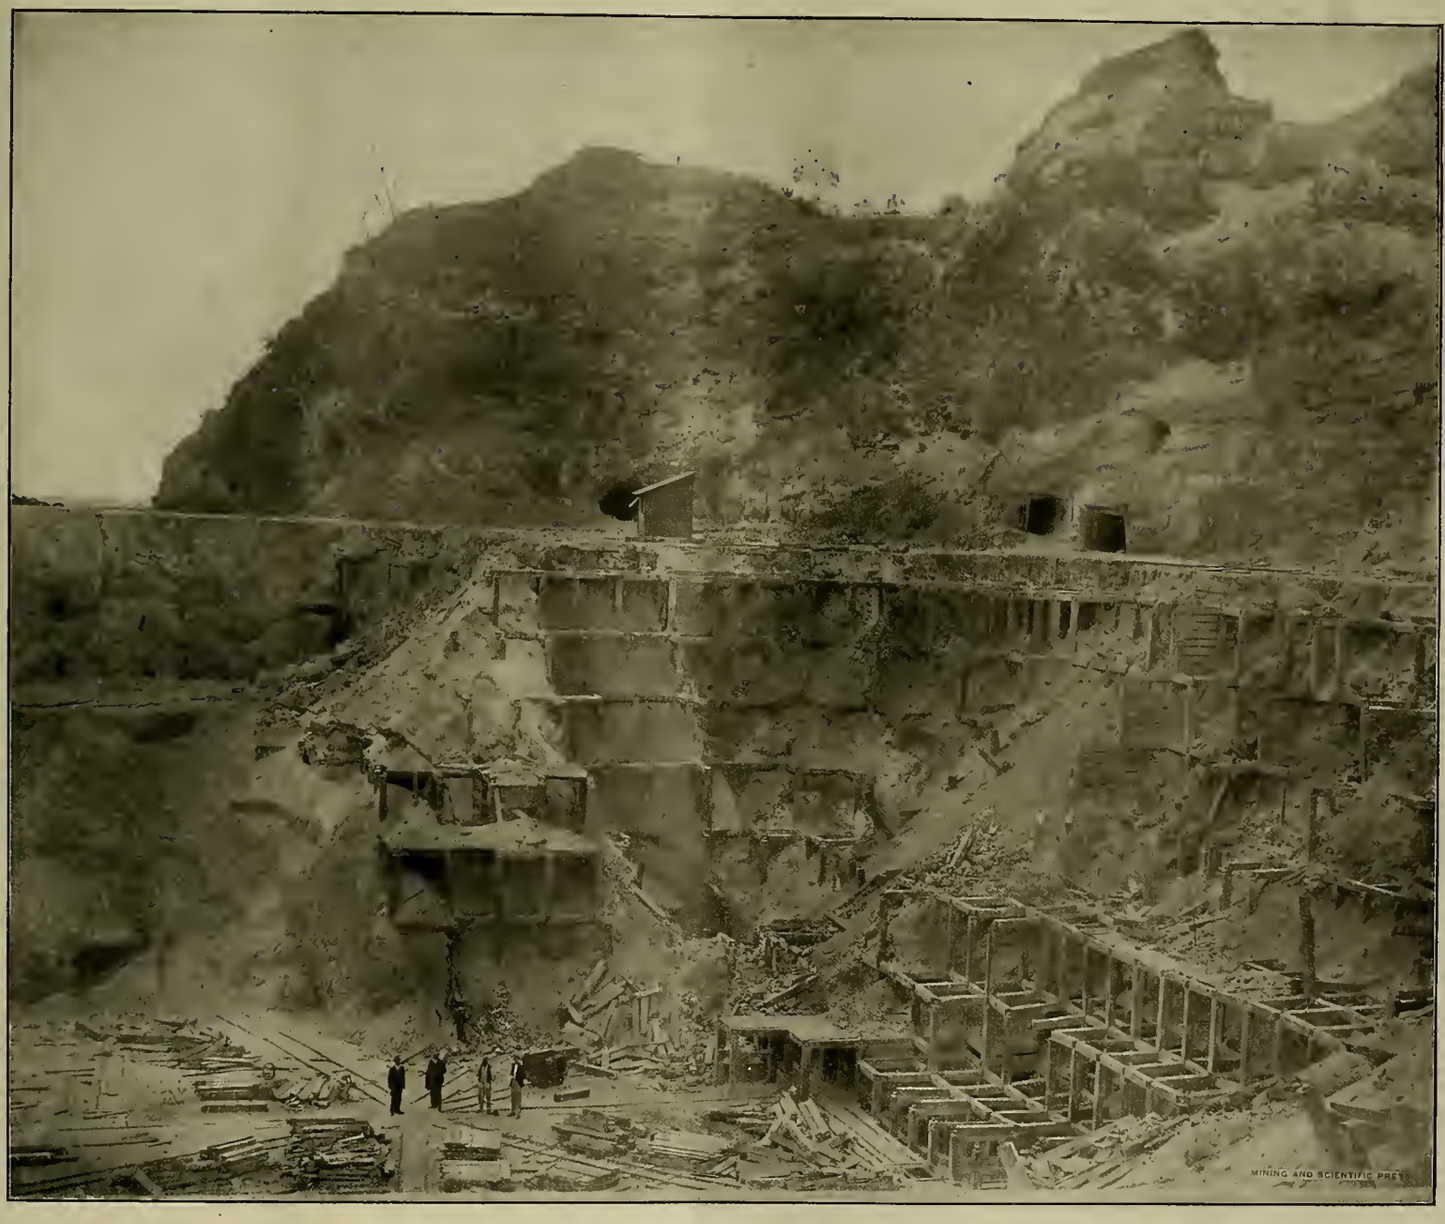
added to bring the water up to .05% solution, or a solution containing one pound of cyanide per ton of water. This material containing a considerable quantity of "cyanicides," enough cyanide was added to maintain a solution of from .025% to .05%.

	Wood Tank.	Iron Tank.
Additional cyanide added at start, lbs. per ton of ore	1 34	1 34
Additional cyanide added end 1 hour, lbs. per ton of ore	1.0	1 0
Additional cyanide added end 3 hours, lbs. per ton of ore	1.0	1 0
Additional cyanide added end 4 hours, lbs. per ton of ore	1.0	1 0
Additional cyanide added end 6 hours, lbs. per ton of ore	1.0	1.0
Assay of heads, ounces silver per ton	17.40	17 40
Assay of tails at end 4 hours, ounces silver per ton	11 70	13 80
Assay of tails at end 6 hours, ounces silver per ton	11.20	14 20
Assay of tails at end 8 hours, ounces silver per ton	11.00	15.00
Per cent extraction at end of 4 hours	32.7	20.1
Per cent extraction at end of 6 hours	35.7	18.4
Per cent extraction at end of 8 hours	36.8	15.0
Cyanide consumption at end of 8 hours	5.0	5.5

Salt Lake City, Utah, April 15. E. L. Godbe.

The Mount Morgan Mine.

One of the most noted mines of the world is the Mount Morgan, situated 26 miles southwest of Rockhampton, in Central Queensland, Australia. The mine is located on a rounded eminence in a range of low hills. It was taken up in 1873 for grazing land, with no thought of its value for mineral. The outcrop of siliceous iron-stone, bearing gold, attracted the attention of a man named Gordon, who sold it to the Morgan Bros. at £1 per acre, the tract comprising 1 mile—640 acres. Some of the ore showed gold, and assays proved the rock to be even richer than the visible gold would indicate. A corporation was formed in 1886 to operate the property. It was capitalized at $5,000,000, but so great was the output that the market value of the shares rose in 1888 to $86,250,000—a figure far above its actual value, but not an infrequent occurrence in connection with rich mines. For several years following its complete equipment the mine paid dividends approximating $5,000,000 annually. The mine occupies, as stated, the summit of a hill, which rises about 500 feet above the neighboring gulches. The surrounding country is hilly and broken. Originally tunnels were run into the hill and underground mining was carried on, but subsequently this method gave place to benching in a series of terraces. One of the accompanying engravings shows the appearance of the hill from the outside with its great dumps of waste, and the other is that of one of the large open cuts, in the side walls of which may be seen the timbers used in supporting the underground workings when operated under the old system. The crest of the hill has entirely disappeared, having been removed by the extensive quarrying operations. The mine furnishes a great variety of ore—dark heavy ore colored by many hued oxides; white porous ore, from which the sulphides have been leached; brown iron stone, ocher-colored earthy material, and in the lowest working abundant sulphides. Recently copper has become an important factor in the output of this noted gold mine. The ore deposit occurs in sedimentary rocks, much altered. Quartzite, graywhacke and slate are the most abundant in the vicinity. The hill on which the mine is situated is cut by several large dikes, and numerous smaller ones are associated with the ore. At one time it was supposed to be a deposit from a geyser, but there has been nothing found in the extensive exploration of the mine to substantiate this theory. The rocks were fractured by the intrusion of the dikes along planes of weakness previously existing, and the mineral solutions permeated the zone of fractured rocks, silicifying them and depositing in the favored places the sulphides, chiefly iron and copper, together with gold. Oxidation produced the rich coloring of the oxides, and leached some of the ore to a porous mass so light that some of it would float upon water, due to the occurrence of air in the honey-combed mass. During the later eighties the mine produced about 75,000 tons of ore annually, from which were derived over four ounces of fine gold per ton. In comparison with the yield of those earlier days the statement of the manager for the month of January, 1904, shows that during that month 19,370 tons of ore produced 9524 ounces 16 dwts., or about 0.5 ounce per ton. In addition to this 1300 ounces were obtained from the treatment of 6705 tons of old tailings, and 21 tons 6 cwt. of copper were obtained as a by-product, containing 81% copper. It is expected the mine will soon produce 15,000 tons of copper ore monthly, which contains 3% copper and 6 dwt. of gold per ton. The monthly output from this source, it is estimated, will reach £40,000 per month. Although the Mount Morgan mine is no longer like the mine of its early history, it is still a large, valuable and interesting property, and its output will still annually approximate that of earlier days, though a far greater tonnage is necessary to attain this result, about 400,000 tons now as against about 75,000 tons in 1889–90. The net returns will not be as great, for though cost of treatment has been greatly reduced, the grade of ore has fallen off in greater ratio.



Open Cut Mount Morgan Mine, Queensland, Australia, Showing Timber in Old Stopes.

Acetylene Flame for Welding.

The process for welding metals by using a blowpipe or burner of acetylene has been developed by a Paris company, says the American Acetylene Journal. The chief difficulty up to the present has been to regulate the proportions of oxygen and acetylene. According to the relative quantities of these gases, an oxidizing or reducing effect is produced.

It is announced that experiments with a mixture of acetyleue aud ether vapor have been successful. The acetylene apparently is passed through ether, by which means it absorbs a considerable amount of the vapor. On igniting the mixed vapors a green flame as small as a pencil point is produced. It is stated that the heat produced exceeds that of the electric arc; this seems rather an exaggeration, but at any rate it very rapidly melts refractory materials. A hole can be made in a bar of iron in a few seconds. In employing it for welding purposes, a file is first passed over the edges to be joined; then a weld is made at the middle and at two other points at the end of the line of contact. Finally, the flame is passed right along this line. With thick plates, the

edges are filed in a particular shape, and then a bar of iron melted by the flame is passed along them to act like solder. The new method is successful with wrought iron and steel, but so far has not been so with cast iron.

Gold Dredging in New Zealand.*

Written by GILBERT WINSLOW.

The method of dredging for gold in "alluvial wash" in New Zealand is the result of thirty to forty years' experiment and improvement. As now carried on, it may be said to be entirely "bucket dredging," for although suction pumps have been tried they have always been discarded.

The essential parts of a working dredger are the pontoons, which form the barge on which all the machinery is placed in position; the ladder frame, including the buckets by means of which the wash to be treated is raised; the revolving cylindrical screen and tables, or an ordinary sluice box, in which the wash is treated; the elevator, not always necessary, for returning the treated wash into the river, behind the dredger, in such position as not to inconvenience dredging operations; and the winches, for altering the position of the dredger by means of ropes fastened to the sbore.

THE PONTOONS.—The pontoons are built of wood or iron. They are always double, with a well about 5 feet in width between them, extending fully half their length, through which the ladder can be lowered.

THE LADDER FRAME.—The ladder frame, of iron or steel, is so arranged that a chain of buckets can travel continuously round its length. The midship, or upper, end of the ladder frame is held at a height of 15 feet to 25 feet above the deck of the pontoons by a strong framing, but the lower end can be lowered through the well to tbe depth required by means of blocks and ropes attached to a bridge-like framing, called the "gantry," on the end of the well. The gantry is so built that the ladder can be hauled entirely out of the water. The buckets discharge their conteuts, when they have passed their highest point, onto a chute which directs the wash to the revolving screen or to the sluice box.

The revolving screen is open at both ends, revolves slowly on its axis, the end which receives the wash being higher than the other end by 1 foot to 2 feet, dependent on the length of the screen. As the screen revolves, material put in at the higher end will be delivered at the lower eud. Water plays on tbe wash in the screen from end to end. The screen is perforated with holes as close together as possible, consistent with strength, and varying in diameter between ¼ inch and 1¼ inch, according to the coarseness of the gold which it is expected to catch. The larger material is delivered from the lower end of the screen into the elevator. All the gold and smaller particles of the wash are washed through the holes, and fall directly onto the tables which have a width equal to the length of the screen, aud a length of about 8 feet or more, if space allows. The tables are covered with plush or felt, having a protection of "expanded metal" laid over it. The fall of the tables may be 1½ inch in 1 foot, and the water frequently flows over the tables with a depth of ½ inch. When once the gold and finer products are on the tables, the separation of the gold is effected by gravitation. The water disintegrates the product on the tables and at the first opportunity the particles of high specific gravity, such as gold and heavy black sand, fall through the expanded metal onto the plusb, where they are caugbt. The lighter particles at the same time are carried away by the water. The stream of water must be so adjusted that it is not sufficiently powerful to move gold particles, and yet is too powerful to allow a mass of fine wash to accumulate on the tables.

DIFFICULTIES IN DREDGING.—It will easily be conceived that gold washed down a river may lodge in a crevice in a rock bottom, and may be absolutely irrecoverable by means of a bucket; for this reason a hard bottom constitutes a serious defect in a dredging claim. Moreover, gold in a face loosened by undermining may fall down and be lost, as far as the dredge is concerned, and thus both the gold on the bottom and that in the higher strata may be lost. Perhaps the most important part of a dredgemaster's work is to see that the bottom is cleaned up, and a few inches of it brought to the surface, for gold appears to work its way into a soft bottom. If the bottom is composed of rock no bucket can clear it effectively.

The presence of too much soft clay, or even of any at all, may prove a source of considerable loss. In general, it has beeu found in New Zealand that in a very clayey ground better results are given by a sluice box than by a revolving screen in the matter of saving gold. It is not difficult to find a reason for this. In a sluice box, any gold in the wash mixed with clay has an opportunity, immediately after the disintegration of the wash uuder the action of a powerful stream of water, to fall to the bottom, between riffles, where the clay lumps cannot reach it. In a screen, however, the gold cannot be expected to go through the first hole it comes to, and that it does not do so in any ground is amply proved by the distribution of the gold across the width of the tables underneath the screen. Until it does find its way through, it will be in constant danger of being picked up by a lump of clay and carried to the elevator and lost.

If a dredge claim happens to be situated in a river into which trees might find their way, and into which much sluicing bas been done, there is a strong probability that there will be a certain amount of buried timber. This, if in large quantities, involves a tremendous loss of dredging time, and may even make a claim undredgable which without dredging timber might be considered ideal dredging ground.

A forest on the land to be dredged must be cleared before the dredger can get to work, and as many as possible of the roots taken out. These frequently are entangled, and may prevent ground which is undermined from falling in, and generally cause great inconvenieuce and loss of time. Nevertheless, a forest does not necessarily condemn a claim, for there are claims in New Zealand with thick virgin bush on them, which are now worked with handsome results. Part of the timber can be burned as firewood.

A dredger working in a flooded river may have its buckets coming up full and be apparently treating a huge quantity of stuff. Yet this may be only river silt, containing almost no gold, which is being continuously washed into the paddock. Sometimes the dredger may even be unable to prevent its paddock from becoming filled up with silt.

If the gold to be caught contains large nuggets, aud a screen be used, some of the nuggets may be too large to pass through the screen, and may become deposited with the tailings. This may be more or less overcome by placing a small sluice box between the screen and the elevator, so that the material delivered from the screen must pass through the sluice box before being elevated. A more likely occurrence, however, is that the gold is too fine to be saved easily and no system of gold saving applicable in the limited space available on a dredger has yet been evolved to meet this case. The device of treating the wash on a separate pontoon has been suggested, but the author has never heard of its beiug carried into practice. Heavy black sand frequently accompanies gold in alluvial ground. On the west coast of the South Island, New Zealand, certain dredging claims exist which are sea deposited and are even only now a few hundred yards from the sea. Here the gold is exceedingly fine, and black sand abounds, so that gold saving operations are rendered exceedingly difficult. Some progress has been made recently, chiefly by using a large spread of tables, a good flow of water, aud a distributing arrangement which makes every part of tbe table do its work. Large quantities of sand might also prevent another difficulty, as sand when run into the paddock behind the dredger might run in underneath it.

Every dredger must be built to suit the requirements of the claim it is intended to work. Many claims have proved apparently valueless when worked by one dredger, which have afterwards given excellent returns when worked by a more suitable dredger. This has beeu due mainly to the fact that the first dredger was either not sufficiently powerful or else was unable to dredge deep enough, and had to leave the best part of the wash on the bottom untouched. In designing a dredge for any claim, it is always necessary to ascertain the greatest depth which it may be required to dredge. If the bottom is so soft that it can be cleaned up easily, it may yet be uneven, or on a regular slope, and so cause difficulty. A ladder of such a length that it will dredge the deeper ground of a claim on being lowered until it approaches a vertical position, has, when in that position, the stresses supported at both ends. If, however, the same ladder be hauled up to dredge much shallower ground, it approaches a horizontal position, and, except for its weight, the principal working stress will be in the direction of its length, and thus the stress will be sideways instead of downwards on the tumbler frame which supports the upper end. In such a position the dredger will frequently "kick" as each bucket impinges against the face. To get rid of this trouble, ladders are sometimes made telescopic, so that they may be lengthened or shortened 4 or 5 feet. The deeper ground may be expected to carry more gold than the shallower ground; it should tberefore not be missed.

Althougb a well designed dredger will probably only need two men per shift, i. e., six men or eight men including the dredgemaster and tbe engineer, yet frequently roads to the grouud must be made, and, if timbered, the timber must be cleared, and possibly cut up for firewood; the cost of labor, therefore, must not be dismissed without thought.

It may be possible to do away with expenditure in fuel by the use of electric power generated by water power. Water power has been used for dredgers with good effect. If, however, steam has to be geuerated, the proximity and cost of coal or wood fuel must be reckoned with. The cost of getting machinery on to the claim must receive as much consideration in dredging as in any other mining proposition.

The wash should not be too coarse, nor should it be excessively hard, due to cement; the proper coarseuess is somewhat difficult to specify. Roughly, however, if the boulders do not exceed 18 incbes in diameter, the grouud is dredgable. Occasionally boulders of 2 feet in diameter may be allowed, and although it has been stated that boulders of ten tons weight have been lifted, they occasion serious inconvenience, and stoppages, if not breakages, will occur. However, it certainly seems that if the wash be coarse the gold has a tendency to be coarse also, and collected in pockets, so that it very frequently pays to move a large boulder, in order to recover what is underneath it.

Prospectiug frequently constitutes a most expensive item, and nearly always an unsatisfactory one. It has been said that the only way to prospect a river is to dredge it.

Bore holes have been put down in a river, but the author does not consider boring tests satisfactory. Wben it is considered that a bore hole of 30 feet in length and 5 inches in diameter contains rather less than one-sixth cubic yard, and that gold nuggets up to one-half ounce in weight may easily be encountered, it is easy to see how misleading a boring test may prove, and no one could expect to get any kind of accurate results. Should the gold be fine and the rods well managed, somewhat more reliable results may be obtained, but even then they cannot be expected to be more than a guide.

The progress made in dredging in New Zealand during the last five years has been due in a measure to the excitement caused by the success attending the efforts in dredging the Molyneaux river. This river has now been found, with the exception of a few miles, to be dredgable for nearly its whole length, or about 100 miles, and as the river flows for about half its length through very rocky gorges, such a result is remarkable. The river flows from Lake Wakatipu, and, to give two instances of its character, its source is a fine waterfall, and about 35 miles below this is a natural bridge of rocks. So rocky is the Molyneaux in parts that one dredger built for convenience on an adjoining claim, was unable to dredge on to the right claim. A large number of claims, which were at their initiation termed "wild cats," are now proved successes. Judging by this, a prospector should not term a gorge undredgable at first sight, for it is not unlikely that it may have a bottom composed of some kind of clayey material, which may prove rich in gold.

Dredging has been accomplished to a depth of 60 feet below water level, and elevating to a height of 60 feet above it. These are extremes, and as the machines to do this work are very costly it is advisable to secure claims somewhat easier to work. At the same time a new type of elevator, working by means of centrifugal force, is now being tried, which, if successful, will greatly reduce the cost of elevators. In general, a depth of 35 feet and an elevation of 30 feet are convenient for a dredger to work.

Claims in New Zealand, which when prospected gave results of 6 grs., over 6 grs., and 1 dwt. to the cubic yard, respectively, have proved failures on dredging; in these cases the prospecting was probably tampered with. The author, without going into details, believes that 3 grs. per cubic yard will give, under good conditions, good results on 100 acres in New Zealand. There, a claim is normally 100 acres, but generally not more than 70 acres of it is dredgable, which may mean a life of about eight years only, and during that time the first cost of the dredger must be paid, as well as a fair rate of interest on the capital expended.

*Abstract Proceedings Inst. C. E.

The Correct Dimensions of Open Flumes.

A matter recently came under my notice regarding the correct dimeusions of open flumes, so as to insure the greatest carrying capacity consistent with using the smallest quantity of material, says T. Cooper in the New Zealand Mines Record. From personal observation and inquiry, I find that this subject receives little attention, and therefore take the liberty of bringing it before your readers' notice.

I find by calculation that by modifying the dimensions of a flume it is possible to materially increase its capacity without any corresponding increase in the quantity of timber used in its construction. The correct relation of sides to bottom appears to be as 1 is to 2.

Taking, for instance, a commonly used flume of 2x2 feet, and, say, 12 feet long, we obtain an area of 4 square feet and a capacity of 48 cubic feet, requiring for its construction 72 square feet of timber. Now, modify the dimensions in accordauce with the proportion above laid down, making the sides to be 1 foot 6 inches and bottom 3 feet. We then obtain an area of 4 feet 6 inches, and with the 12-foot box, a capacity of 54 feet, still using only the same quantity of timber—72 feet.

Other examples work out similarly, e. g.:

Sides.	Bottom.	Length.	Area. Square Ft.	Capacity. Cub. Ft.	Timber Sq. Ft.
3 feet	x 3 feet	x 12 feet.	9	108	108
2 feet 3 inches	x 4 feet 6 inches	x 12 feet.	10.125	121.5	108
2 feet	x 3 feet	x 12 feet.	6	72	84
1 foot 9 inches	x 3 feet 6 inches	x 12 feet.	6.125	73.5	84
3 feet	x 4 feet	x 12 feet.	12	144	120
2 feet 6 inches	x 5 feet	x 12 feet.	12.5	150	120
4 feet	x 4 feet	x 12 feet.	16	192	144
3 feet	x 6 feet	x 12 feet.	18	216	144

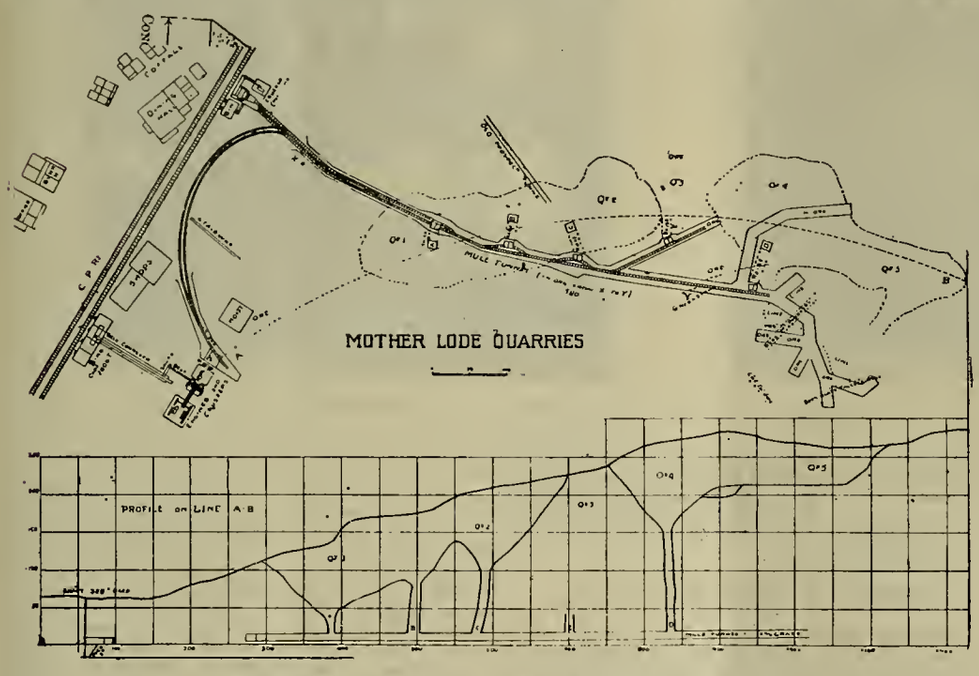
In these examples I have, in order to simplify calculations, taken no account of the loss of timber entailed at the junction of sides and bottom; but this will not affect capacity results.

Mining in Boundary District, B. C.

Written by Fred'k Keffer, M. E.*

Two years ago the writer described the methods employed in mining low-grade ores at the Mother Lode mine, in the Boundary district, B. C. It is the purpose of the present paper to briefly note developments of the system, particularly as regards the quarrying and economical handling of ores, and also to touch upon certain features connected with smelting operations.

At the Mother Lode the series of quarries has been extended and there are at present four raises to the quarries from the main tunnel, with a fifth in course of driving. As far as is possible, the tops of these raises are maintained funnel-shape so as to reduce to a minimum the handling of the ore. While the pits remained shallow it was an easy matter to remove barren or very poor rock by loading it into cars and tramming to waste dumps, but as the funnel system developed it became inadvisable to remove any except large bodies of waste, for the cost of removal had become greater than the cost of smelting. Experience has shown, however, that the detrimental effects of these smaller bodies of waste have been more than offset by the improvement in the general run of the ore body, due to lesser quantities of partially leached surface rock being included; so that the average copper contents of the 137,800 tons mined in 1903 were appreciably higher per ton than those of the 135,500 tons mined in 1902. In places, however, large dikes of epidote, and alkali porphyry, and occasionally isolated bodies of limestone, occur, which are removed by blasting into the raises, all the ore having been previously withdrawn.



Plan and Section of Mother Lode Mine, Boundary District, B C.

The crusher plant located at the entrance to the quarry tunnel has dealt with the quarry ore alone, that from the stopes having been crushed by a Gates machine installed at head of shaft. Work is now being carried forward to consolidate the crushing plants and do away with the machine, which is inadequate to the demands now made upon it. To this end a tunnel is being driven to intersect the main shaft on the same level as the quarry tunnel. At the shaft will be placed a large pocket, and this will discharge the ore into 5-ton skips which will replace the cages now used. The skips will empty into a bin at the head of the shaft, ore passing thence to either one or two crushers, each crusher having a jaw opening 2 feet by 3 feet. These crushers will be driven by a pair of 100 H. P. engines so arranged that either engine can drive either crusher, this arrangement to eliminate all chance of stoppages through breakdowns in either engines or crushers—stoppages which past experience has shown to be inevitable as well as costly. The crushed ore will be conveyed by a Robins belt to the main ore bins. All car dumping and opening of bin and pocket gates will be done by means of compressed air. The same skips and crushers will, of course, serve all levels in the mine.

Although the ore will have to be hauled farther under the new arrangement, crushing costs will be lowered, for the reason that, aside from stoppages for repairs to machinery, the provision of capacious pockets and shaft bins insures steady operation of crusher, which machine, if constantly supplied with ore, can crush a furnace day's run in a single shift, instead of this work taking a shift and a half as at present. Jamming of elevator buckets, constant repairs to them, and their clogging with frozen fine ore in winter, all serious drawbacks to rapid work, will be avoided. The short tunnel to shaft will become the general entrance to mine, both for men (whose houses are all on this level) and for materials from shops and store houses. The main features of this work are shown in the reproduced photograph of map of the mine.

In the matter of power, the cost of this item at the mine has been greatly reduced through the consolidation of power plant, and the driving of all machinery by compressed air. The 100 H. P. crusher engine, formerly steam driven from boilers located near by, now uses compressed air, which is heated to a considerable degree just before entering engine. This expedient has effected a direct saving in labor and fuel to the amount of from 5 to 7 cents per ton of ore crushed. Air is furnished by a cross compound condensing compressor, capacity 3200 feet free air per minute. Two boilers situate near the crushers and hoist will be available to furnish steam on short notice should the compressor machinery break down, thus guarding against stoppages from this cause.

From a smelting standpoint, the ores of the larger Boundary properties have, as a rule, grown less basic as the works have been extended and deepened. That is to say, the proportion of iron oxide ores to the whole ore body has sensibly diminished, there being no great change in the amount of other base. Whether or not this reduced proportion of base to acid ore is to be permanent, it is (at any rate in the case of the Mother Lode mine) impossible to predict. Long experience in mining these deposits has shown that it is not possible to make safe predictions as to occurrence of zones of mineralization, new ore bodies frequently having been found in unexpected places. On the 200 foot level of this mine there has been found considerable less oxide of iron ore than in either the quarries or the 300-foot level. The iron oxides of this latter level are uniformly of higher grade than those of the quarries, carrying more copper and gold, and they do not appear to be directly connected with the upper deposits, although this is not absolutely proven. No exploratory work has yet been done beneath the 300-foot level (which is about 500 feet under the highest outcropping of the ore). A large body of iron oxide ore occurs at the mouth of the main tunnel, but no work has yet been done on it owing to close proximity of the crusher plant, which would be damaged by flying rocks were the requisite blasting to be done.

The change in the basic character of the ore is illustrated by the following average slag analyses, taken over corresponding periods of 1901, 1902 and 1903. The small tonnage of foreign ores treated affects the assays somewhat, but not materially:

Year—	Silica.	Iron.	Lime.	Total.
1901	33.3%	28.5%	20.6%	82.3%
1902	40.5	22.2	20.2	82.9
1903	42.7	20.4	20.2	83.3

With slags running in silica from 40% to 43%, and with matte at 40% to 45% copper, it is found that the furnaces can be maintained in good running condition, and slag losses kept within proper limits. To guard against possible scarcity of iron fluxes it has, therefore, become the general practice to conserve the iron ores of the mines, using only sufficient to keep slags within bounds above indicated.

* B. C. Mining Record.

Cyaniding Gold-Bearing Sulphurets.*

NUMBER IV.—CONCLUDED.

Written by S. B. Christy.

I frequently find that in extracting those ores such a thing as this happens: First, the gold comes out abundantly and very little silver. After a while the solution contains more silver than gold. That goes to show that the gold being more accessible at first is removed, and then, being covered up by the silver, only the silver is touched. I have always found these ores very difficult to treat. I will mention one case of an ore containing about thirty ounces of silver and about two or three ounces of gold. It contained a lot of arseuide of iron, antimonide of iron, lead, copper, zinc and several other minerals. The best I could do on it was about 40%. So do not attempt to apply this on a large scale until you have tried it on a small scale, and then only if it works on the small scale is it wise to attempt it on the large scale.

As to cost, it is rather difficult to make an estimate. It depends in the first place upon the number of tons of ore you treat in a day. One of the difficulties in California is that our mines are located mostly widely separated from each other, and it is extremely difficult to get any one point easily accessible to a large number of mines, where the ore from a large number of mines can be treated. There are only a few places in the State where that is possible, and it therefore results that there are small batches of sulphurets produced at isolated points, where perhaps a mine produces only one or two tons a day, and it is very difficult to put up a plant to handle that small amount economically, but where you have five or ten tons of sulphurets a day, and you have cheap water available for grinding, I see no reason why these sulphurets cannot be treated, when they are properly composed for favorable treatment, of at least 90% or 95%, at a cost of $5 a ton or less, and under favorable conditions $25 material which now does not pay in many cases, might yield a profit of at least $15 a ton, and probably more.

At the present time a great deal of attention is being paid to this subject all over the world. In Australia they are making very earnest attempts to solve the problem, and recently in South Africa they have attacked it there, and I am glad to say, for the first time in years along rational lines. I have recently read a number of papers in the transactions of the South African Mining Association, which showed they were beginning to realize the importance of fine grinding and plenty of water, though they had not yet fully realized, apparently, the importance of getting rid of the metallic iron. But it is along the lines I have indicated here that the problem is to be solved. I feel very sure, if this subject is given the right kind of attention, close and persistent it must be, that it will be easily practicable to add to the annual output of our California mines from $5,000,000 to $6,000,000 a year, because it will mean that a large number of mines which now lie idle because they just contain free gold enough to pay expenses, will become producers, and profitable producers as well.

There is another thing I should have mentioned; that is, the treatment of the iron removed by the magnetic separator. You will see if you remove from 1% to 2% of magnetic material from the sulphurets, you have left a material which contains some gold that has not been treated. So far I have not found any satisfactory way of treating that except to roast it. You may say that will bring us back to chlorination. I don't believe so, because a very small roasting furnace would do. You roast the iron and convert it to the red oxide of iron; then it may be ground fine, either alone or mixed with the rest of the ore, as it is now perfectly harmless to the cyanide solution. Thus you only have to roast a few per cent of what you would if you chlorinated it.

As to the removal of the magnetic material from the sulphides, which should be done before roasting, I had to do it dry. I used a little machine on the plan of the Wetherill magnetic concentrator. The Wetherill people have a concentrator which works under water on wet pulp, and though I have not tried that I feel sure it will work. There is a powerful electric magnet on two sides of a moving belt, and the ore pulp fed into a stream through the field of either magnet, and the non-magnetic part falls into a hopper. A belt with brushes travels around between the maguet poles and sweeps the magnetic part off and dumps it off into a separate hopper. It is a very simple apparatus, which can be easily used. I will say, also, in some cases where the ore is very soft and very little iron produced, you might not need to separate the iron at all, and in any case you would not need to separate it if you are willing to put up with a great loss of cyanide, but that affects the cost. Of course, it is advantageous to circulate the solution so as to use it over again repeatedly, as is done in leaching, but as this is so familiar to cyanide men I did not think it necessary to mention it. But by utilizing the principle of opposed currents, as was first done in decantation treatment by Mr. Williams in South Africa, the volume of solution that must be precipitated can be much reduced.

*Abstract Trans. Cal. Min. Ass'n.

A Compressed Air Installation.

Written for the MINING AND SCIENTIFIC PRESS by WALTER W. BRADLEY.

Much is being said and written along scientific as well as practical lines of the various phases of mining installations. Of these, the question of power is receiving its share of attention, as between water, electricity, compressed air or steam. Water is used argely as the prime mover in the production of both electricity and compressed air. The one advantage of electricity which stands out above all others is its susceptibility to long-distance transmission—present installations reaching up to 300 miles. It may be used direct-connected or belted, or it may be used to compress air, which in turn is used direct. In the latter case, however, at many mines it might be cheaper to compress the air directly with the water power, without electricity as an iutermediate stage. Compressed air is of manifest value around a mine, and especially underground, where, after it has done its work as an agent for power, the exhaust serves to aid ventilation. Electricity, too, is being applied to the operation of rock drills. Compressed air is used in pumps, hoists and other engines in lieu of,

Fig. 1.—North Star M. Co. Compressed Air Power Plant, Grass Valley, Cal.

Fig. 2.—Hoist at Central Shaft, North Star M. Co., Grass Valley, Cal.

and as interchangeable witb, steam, as will be observed below.

An important installatiou in the way of compressed air power plants is illustrated herewith in Fig. 1, being that of the North Star mine, near Grass Valley, Nevada county, Cal. At the time the photograph was taken the plant had a capacity for producing 500 H. P., but this bas since been increased to 800 H. P. One of the compressors therein is driven by a tangential water wheel, 30 feet in diameter, using a single jet under pressure of 775 feet head. A speed of 65 revolutions per minute is maintained and the compressor has automatically operated governors, which (set at 90 pounds pressure per square inch) cut out (blow off) the excess of air not being uscd, down to 15% of the volumetric capacity of the cylinders. This 30-foot water wheel was designed to withstand up to 200 revolutions a minute (a peripheral speed of about 20,000 feet per minute). The first wheel put in was of 18½ feet diameter, to run at 110 revolutions per minute, under 750-foot head, developing 300 H. P. The compressor is direct-connected to the 30-foot wheel, and is of four single-acting cylinders—oue low and one high pressure on each side—having a common stroke of 30 inches. The low pressure cylinders are 30 inches in diameter aud compress the air to 25 pounds per square inch. The high pressure cylinders are 18½ inches in diameter and raise the pressure to 90 pounds per square inch. Between the high and low pressure cylinders the air passes through a series of cooling pipes set in the waterway of the wheel pit.

The compressed air is conveyed by pipe lines to the several workings of the company, the principal one of which is the Central shaft and its connections. The hoist used there is shown in Fig. 2. It is of double-drum, direct-connected, with both post and band brakes, and bas a capacity for raising 2400 tons per day from 1625 feet depth. Allowing 2 minutes for a round trip, hoisting in balance, with 3 tons of rock per skip, this would require 13⅓ hours, leaving 10⅔ hours for handling tools, timber and men and hoisting water. The compressed air before use in the engines of the hoist is reheated by crude oil in a furnace placed in a separate room to the rear of the engineer.

The Central shaft at a depth of 600 feet cut the New York Hill vein, and at a depth of 1625 feet the main North Star fissure was struck, being about 4000 feet on the dip of the vein. A 50-foot sump was sunk and stations cut for ore bins and pumps. From there a raise of 1600 feet was driven in the vein most of the way, and cutting the bottom of the old workings. That the ore values are well maintained throughout this entire depth is shown in the annual report of President Hague of the North Star Co. (see MINING AND SCIENTIFIC PRESS, March 26, 1904, p. 217). Of the values, 90% is in free gold, and the ore carries 3% auriferous sulphides, principally pyrite, but with some galena. The Central shaft is sunk in grano-diorite and in diabase, the contact crossing the shaft irregularly and sometimes following down the center line. However, the two formations were found so tightly "frozen" that the contact never showed any "let go."

Two triple expansion, duplex pumps in the station at the bottom of the shaft raise from 500 to 700 gallons of water per minute a height of 1400 vertical feet in a single lift. These pumps use air at 90 pounds pressure, reheated by crude oil at the pumps. For the rainy period in the spring it is necessary, in addition to the pumps, to use a 3-ton bailing tank. Ventilation in the workings passes down the incline and up the vertical shaft, partly due to the collar of the Central shaft being 50 feet bigher and partly because the gases from the oil combustion in tbe air heaters are discharged up into the vertical shaft. The draught is so stroug as to blow out a lighted candle. To provide milling facilities for the increased ore reserves opened up by these developments, the 40-stamp mill at the North Star (incline) shaft is being remodeled and a new 40-stamp mill is being built at the Central shaft.

Interlocking Metal Sheet Piling.

The advantages to be gained by the use of interlocking steel sheet piling for use in construction of cofferdams, for placer mining, sinking of mine shafts in running ground, and all kinds of earth excavation, particularly where quicksand is encountered, are becoming manifest. The primary object is to provide a metal sheet piling, in which standard rolled beams and plates are used in such a way as to have their adjoining edges interlocked during tbe process of driving. In most cases, the sizes of the beams and plates will be 4-inch Z-bars, 6-inch by 3½-incb angles, and 15-inch wide plates, all of ⅜-inch thick metal. The rolled sections can now be obtained up to 60 feet in leugth, and it is therefore possible to use this piling in one length without splicing the same, if this is deemed advisable. The shapes and plates are put together with Z-bar riveted at one edge of the plate and an angle spaced from tbe plate and extending around the other edge of the plate, thereby forming grooves or channels to receive the adjoining section. One of the interesting features in this construction is the method of caulking the joints. To render the structure water tight, when the same is driven in clear water, a wood strip is provided, and held in the angle where the piles join by means of Z-bar clips and bolts. Slotted holes are provided in the flanges of the Z-bar which permit of the adjustment of the Z-bar closely around the wooden strip. The wooden strip will swell in such situations and present a good joint which requires no further calking. Local leakage can be readily calked when it arises. In running ground or sand, the wooden strip can be omitted, as the joint will readily calk itself by the accumulation of sand, etc. The piling cau be pulled and redriven any number of times, and when it is to be put to no further use, it can be discarded at scrap value. The piling is driven with the ordinary pile driver; it is the iuvention of H. Wittekind, of Chicago. The piling is manufactured by the H. Wittekind Interlocking Metal Piling Co., with offices 611 Cable Building, Chicago, Ill.

Water Consumption in Ore Treatment at Kalgoorlie, W. A.

TO THE EDITOR:—The accompanying tabulated statement shows the water consumption for the principal mines of Kalgoorlie. Some of your readers are no doubt interested in knowing just how far a limited supply of water will go in general mining and milling operations, and it is very seldom that such reliable data as this can be obtained. The tons treated per month can be relied upon as being accurate, as the mines are required by law to render monthly statements. The mines are all under contract to purchase the whole of the water consumed from the Government; and in consideration of the exclusive use of the Government supply they enjoy a rate of 5 shillings per 1000 gallons, and at this rate the mines are obliged to turn tbeir mine water to waste. These quantities include water for all purposes of mining, as well as an allowance of two gallons per day for each employe, and the household supply for tbe staff employes living on the leases.

All the mines of the group have their own steam power, which is used for hoisting, pumping and milling, and the quantities include tbat used for cooling and condensing, and it is principally owing to the character of this apparatus that the variation in consumption is due.

Some modification of the cyanide process is used in every instance; and those using the dry process, roasting the entire ore, would of course have a higher consumption than those using the wet process, owing to the fact that the ore of the district contains a considerable quantity of carbonates which are converted by roasting into sulphates, and these absorb a large amount of water in the subsequent cyauide treatment. The average consumption in the dry process plants is made lower than would otherwise be owing to the fact that the Great Boulder Persevcrance plant is equipped with Fouche condensers, aerial type, while other mines almost exclusively are supplied with water cooling and condeusing plants.

The mines all use filter presses, and the discharged residues vary in moisture from 10% to 25%.

The table is based on the long ton of 2240 pounds and the imperial gallon of 10 pounds.

WATER CONSUMPTION FOR MONTH OF DECEMBER, 1903.

Dry Processes.	Tons Treated for Month.	Gallons Per Ton.
Associated Gold Mines	5,840	256
Associated Northern	2,152	382
Great Boulder Main Reef	2,023	242
Great Boulder Perseverance	11,112	158
Great Boulder Proprietary	9,324	280
Kalgurli	4,571	323
Average consumption per ton, dry processes		234.4
Wet Processes.		
Golden Horseshoe	13,170	234
Rainault	2,205	247
Ivanhoe	12,470	195
Lake View Consols	7,362	208
Oroya-Brownhill	7,009	199
Hannan's Star	1,566	243
Average consumption per ton, wet processes		209.7

Boulder, W. A., Feb. 26. D. E. BIGELOW.

THE local members of the American Institute of Mining Engineers, including the State of Missouri and the adjoining Illinois territory, met on the 9th inst. at the rooms of the chief of the department of mines and metallurgy to prepare for entertaining the mining engineers and metallurgists during the World's Fair. The meeting organized by clecting Arthur Thacher, president of the Central Lead Co., as chairman; F. E. Drake, manager of the Lanyon Zinc Co., as treasurer, and H. A. Wheeler, superintendent of the mining reservation at the World's Fair, as secretary. It is the intention to appoint about twelve vice-chairmen, each of whom will be

prominently identified with the different mining, metallurgical or technical industries of St. Louis and vicinity. Their names will be announced later. The headquarters of the local committee will be in the Mining and Metallurgy Building at the World's Fair, where an attractive space has been allotted to the Institute of Mining Engineers. Affiliated interests are invited to correspond with the secretary, H. A. Wheeler, Mines Building, World's Fair, who desire to co-operate or wish further information.

Scale in Steam Boilers.

Written by V. O. LAWRENCE.

That nearly all water used for the production of steam contains solids, which upon evaporation of the water form boiler scale, is well known to engineers generally, but it does not appear to be so well knowu in what manner that scale is formed, or what chemical reaction takes place to cause the formation.

These solids may be classed separately as sulphates and carbonates. The carbonates consist of the calcium carbonate and magnesium carbonate, both of which are held in solution by reason of their excess of carbonic acid.

From a temperature of about 180° F. to the boiling point and above, this excess of carbonic acid is driven off, and the carbonate of lime, or of magnesia, robbed of its solvent, deposits. An exceptionally high temperature is not necessary to effect this separation, and it is for this reason that we find carbonates to deposit in feed-water heaters and economizers, as well as at the point in the boiler where the feed-water enters.

The carbonates when existing in water without any calcium sulphate being present form a porous accumulatiou, varying from a crystalline to amorphous formation, and even occurring as a fine powder. The latter is more often the case when the feed-water coutains in solution a considerable quantity of sodium chloride (common salt).

Calcium sulphate, which is held in solution by nearly every natural feed-water, is not precipitated at the comparatively low temperature mentioned. In an experiment made in the laboratory a water heavily saturated with calcium sulphate was heated to a temperature produciug ten pounds of pressure, but no precipitation of the calcium sulphate was caused.

Some authorities claim that the separation, or the change of the calcium sulphate from solution to suspension, takes place on the surface of the water in the boiler. If this were a fact the calcium sulphate scale would accumulate in those parts of a boiler nearest the water surface. The contrary, however, is the case, as scale of this nature invariably forms at the parts of the boiler which are exposed to the highest temperature.

It is for this reason we claim that the actual separation, from a certain quantity of water. takes place the moment that quantity of water is changed into steam, and we claim that this change takes place at the point where the heat is transmitted through the iron of thc boiler into the water.

When an atom of water reaches a sufficiently high temperature to become steam it forms a miuute globule, rises through the water to the surface, where the slight coating of water covering the globule breaks. At the point where this globule is formed, that is, at the heating surface, there being nothing to hold the calcium sulphate either in suspension or solution, it must separate, and forms a very small crystal.

If the ebullition of the water is not sufficieut to dislodge it, it will adhere to the iron at the point where it had its origin, or it may be carried by the circulation until it finds something to which it can adhere.

The scale which is formed of calcium sulphate alone is very hard, but a formation of this kind is rare, the great majority of scales consisting of the three substances mentioned, as well as other mineral and vegetable substances.

These latter substances, which are held in suspension by water, instead of solution, become part of a body of scale only mechanically. That is, they become part of a scale, like sand becomes part of mortar, when mixed with cement, the cementing substance in scale being first of all calcium sulphate, magnesium and calcium carbonate being secondary.

Calcium sulphate is the substance commonly known as plaster of Paris. Calcium carbonate exists in nature as marble, while magnesium carbonate is the material often used for covering steam pipes, to prevent the loss of heat.

From the very nature of scale-forming substances their accumulation is a source of trouble to the engineer and expense to owuers of plants. There are, no doubt, many cases where additional expense does not worry the engineer, but there are also, doubtless, more cases where the additional trouble to the engineer does not worry the owner of the plant. There is no question, however, but that both would be benefited if the accumulation of the scale could be prevented and taken care of.

The problem is a difficult one, as not only does each source of water vary greatly in the scale forming solids, but each individual source varies from time to time. One can readily see, therefore, that the analysis of a single gallon of water does not give a great deal of information, as each sample of scale represents the residue left after the evaporation of large quantities of water. We, therefore, contend that if a sample of scale is divided and separated into its various ingredients, chemical treatment can be undertaken successfully. Without such determination, however, it is an impossibility to provide reagents which on the average can be assured to give satisfactory results.

If it were possible to compute the loss in fuel alone from this cause the results would reach an enormous total, and would call the attention of the owners and engineers of plants to the great importance of the subject.

Concrete in Mining and Metallurgical Engineering.*

Written by H. W. EDWARDS.

Concrete is not a new, nor even a modern, substance. Important structures built by the old Romans before the commencement of the Christian era are to-day sound and solid—for example, the dome of the Pantheon in Rome, 142 feet in diameter. I do not propose to discuss the durability of the material, as in the mining and metallurgical business structures, as a ruie, are not calculated to endure for 2000 years. I wish to urge, however, that much of the stone masonry around mines and smelters would have given better results if concrete had been used in place of stone. Concrete looks better, is stronger, cheaper, more durable, more quickly built, and, above all, requires no skilled labor except the carpenter.

Concrete, having well-proportioned ingredients, may be safely relied upon to withstand a compressive or crushing strength of 50 tons per square foot. In most American cities, however, the building laws limit it to the absurdly low figure of 16 tons.

The weight of good concrete, dry, is from 130 to 160 pounds per cubic foot.

INGREDIENTS OF CONCRETE.—Concrete is composed of four ingredieuts, i. e., crushed stone, sand, cement and water.

CRUSHED STONE.—The stone is usually crushed to a size that will pass through a ring of from 2 to 2.5 inches in diameter. It is not necessary nor even beneficial to screen the material. Soft rocks, as sandstone or soft porphyry, are not to be recommended unless the concrete is to bear either no load or an insignificant one. Slag roughly broken to from 2 to 2.5-inch size is suitable. The only objectionable ingredient in slag is calcium sulphide.

COARSE, GRAVELLY SAND.—Jig tailings, both coarse and fine (7 millimeters and under), give good results, especially the 2.5-millimeter size. A mixture of all sizes, with the from 1.5 to 2.5-millimeter sizes predominating, is perhaps the best form in which to use jig tailings. Vanner tailings and stamp battery tailings are not so advantageous, being usually too fine in size. Granulated slag is excellent.

CEMENT.—Cement is essentially a combination of lime with aluminum silicate. A few deposits of rock are known in which limestone and clay occur in about the proper proportions to form cement, and in these cases it is only necessary to calcine and pulverize such material to obtain the so-called "natural cement." Louisville, Milwaukee and Akrou are well-known points supplying such a product. The calcination has to be skillfully conducted at a low heat. If burnt at too high a temperature, it fuses to a slag, which, when ground, exhibits no cement qualities. Moreover, the rock seldom contains the true proportion of lime and alumina, and contains, as well, other

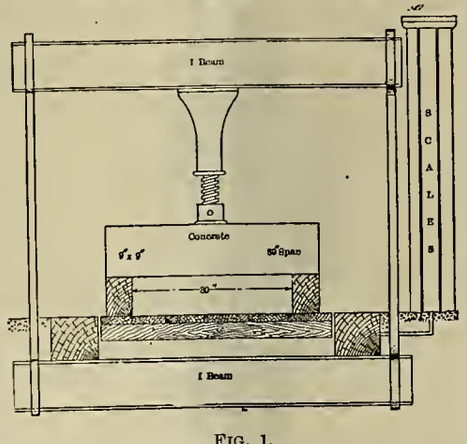


FIG. 1.

substances of an undesirable nature, as, for instance, magnesia. For these reasons the natural cement, while much cheaper in first cost, is usually much less effective than the artificial cement. If any doubt exists as to whether any particular sample of cement is natural or artificial, a test for magnesia will usually settle the matter. In Portland cement magnesia is only a slight accidental impurity (2% or so), while in natural cement it sometimes exceeds 10%. Portland cement only is referred to in the following mixtures.

*Abstract Trans. Am. Inst. Min. Engs.

The tensile strength of a block of concrete may be tested with an ordinary 5-ton platform scales and a jackscrew. Fig. 1 shows the method, and the details are sufficieutly plain without detailed description—the pressure exerted by the jackscrew being read off on the scale beam at the moment the cracks appear on either of the visible sides of the test piece.

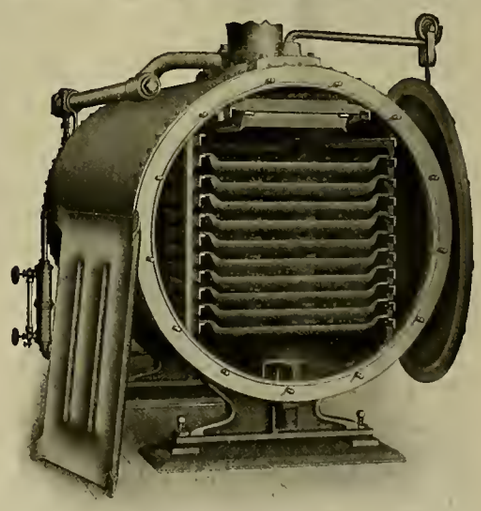
Several prelimiuary series of mixtures of the various ingredients in various proportions should be made—a series with each brand of cement. The mixtures should be rammed in a wooden box, 9 inches square and 30 inches long, inside measuremeut, and left therein for several days or weeks until set. Several batches should be mixed, varying both with the nature and the proportious of the ingredieuts obtainable, and several casts made of each batch. A series of mixtures is suggested as follows:

Cement, Parts.	Sand, Fine Gravel or Tailings, Parts.	Crushed, Unscreened Rock, Parts.
1	0.5	7
1	1	6
1	2	5
1	3	4
1	4	3

(TO BE CONTINUED.)

Exhaust Steam Feed Water Heater.

Herewith is illustrated a feed water heater designed to secure efficiency from the use of exhaust steam, obtained by bringing the water in direct contact with the steam on its passage through the heater, especial provision being made for catching and retaining the solids which separate at the temperature obtained, which is about 210°. Prevention of oil from the exhaust steam becomiug mixed with the feed water is also designed to be provided for; automatic regulation of the water to the heater is secured by float and balanced valve. The heater shell top is of sheet steel, the bottom to a point well above the water line, of cast iron. The heads are cast iron, the front or removable head being swung on a crane as shown, when it is desired to open the heater for cleaning. The trays or pans are of gray



Hoppes Exhaust Steam Feed Water Heater.

iron castings, the form is made up of a series of trough-shaped sections in such manner that the water will flow over the sides and euds, also through the slots, and follow the under side of the pans to the lowest point, from which it drops into the uext pan below. The water in flowing over the edges and along the under side of the pans is brought in direct contact with the exhaust steam and then heated to the maximum temperature obtainable.

When the heater is ready to be cleaned the upper pans will often be found coated with lime and other solids an inch thick, the lower pans being but slightly coated. To clean the heater the head is removed and the pans drawn out when the lime can be scraped off, the pans washed and returned to the heater. The lime will not form on thc shell or other parts of the heater as the water does not come into contact with it until it reaches the chamber at the bottom, and when the pans are cleaned the process of cleaning is complete.

A large oil catcher is located at the back end of the heater through which the exhaust steam passes, and which eliminates the oil and grease from the exhaust steam. The heater is built with especial reference to being non-corrosive from the action of acids in the feed water. All parts of the heater which come into contact with the water are made of cast iron.

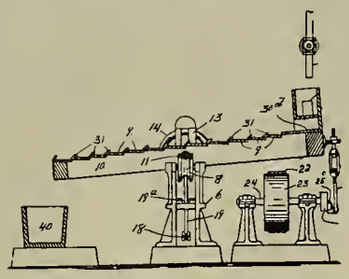
This heater is manufactured by the Hoppes Manufacturing Co., No. 39 James street, Springfield, Ohio.

Mining and Metallurgical Patents.

PATENTS ISSUED APRIL 12, 1904.

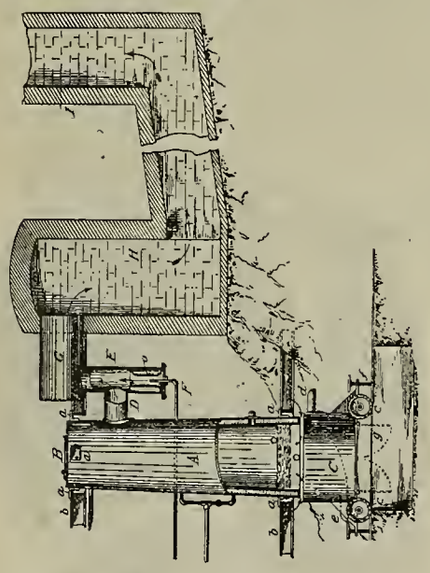
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

CONCENTRATOR.—No. 757,350; J. Ruedy, Denver, Colo.



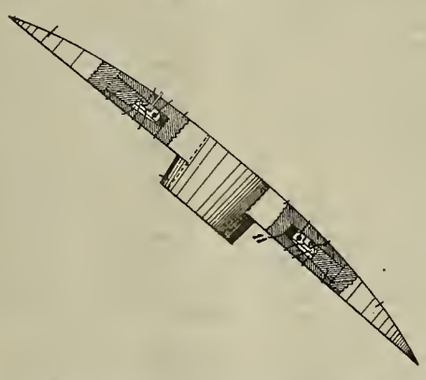
Concentrating table composed of number of longitudinal pans widest at center of table and diminishing in width toward opposite edges thereof arranged to have transverse intermittent discharge from one to other, discharge being completely interrupted during rocking stroke of table in one direction, pans or shelves being provided with riffles projecting above discharge edge and shaped to hold concentrates on pan, and means for simultaneously imparting to table longitudinal reciprocation and rocking or oscillating movement.

PROCESS OF SMELTING ORES.—No. 757,220; A. R. Partridge, San Francisco, Cal.



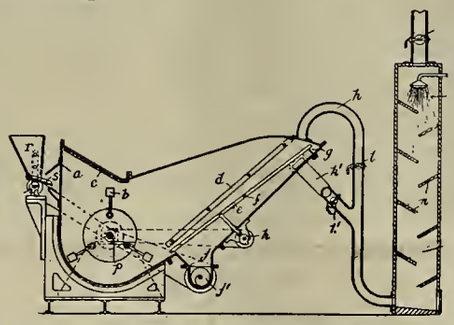
Method smelting ores consisting in admitting air freely at atmospheric pressure to bottom of smelter, and producing suction at top of smelter by injecting jet of steam or air through relatively narrow passage, causing steam or air to pass transversely an outlet from upper end of smelter and to then expand to fill relatively wider passage beyond outlet.

PICK AND POINT.—No. 757,206; L. Kovacs and M. Kovacs, San Francisco, Cal.



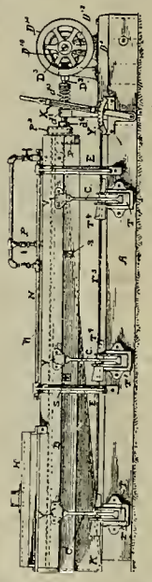
Combination in pick of body portion having handle socket and extensions at each side, extensions having tapering rectangular sockets leading inwardly from center of outer ends, pick points having centrally located shanks adapted to fit sockets, shanks being provided with engaging catches and corresponding latches pivoted within and protected by walls of sockets and adapted to engage with catches of pick point shanks.

IMPACT ORE PULVERIZER.—No. 757,069; J. Thame, London, England.



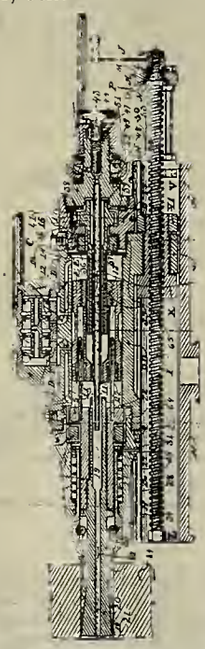
In pulverizing mill, combination with casing, rotary beaters mounted therein and means for feeding material to beaters, of screen within casing, delivery outlets in casing at front and back of screen for dust and delivery receptacle beneath screen adapted to receive and deliver graded material.

ORE CONCENTRATOR.—No. 757,008; G. E. Woodbury, San Francisco, Cal.



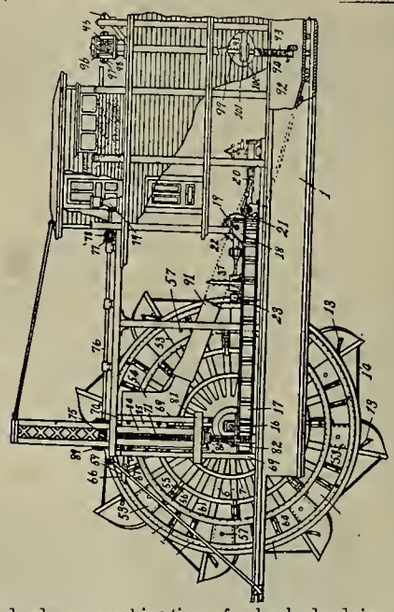
In ore concentrator, reciprocating table, wooden strips thereon disposed in parallel rows, and extending from one end of table surface for portion of length thereof, and relatively thin metal strip of metal of same width as wooden strip and fastened on top of wooden strip, metal strip extending beyond wooden strip and being fastened directly on surface of table beyond terminal end of strip, extension forming continuation of riffle.

METHOD OF EJECTING ROCK CUTTINGS FROM HOLES IN ROCK WHILE DRILLING THEM.—No. 756,972; J. G. Leyner, Denver, Colo.



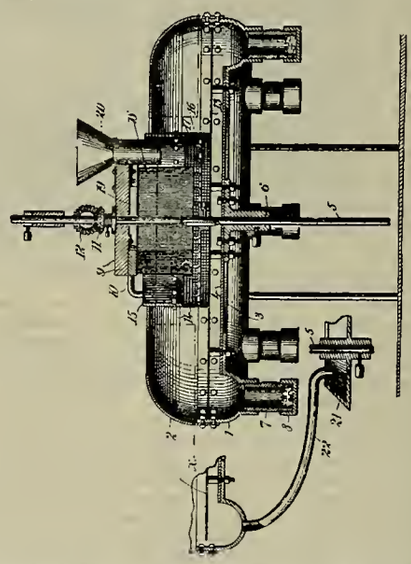
Method of expelling rock cuttings from holes in rock during process of drilling holes, by simultaneously supplying to holes during drilling operation water and air under pressure at the drilling point during drilling operation.

DREDGER.—No. 757,173; A. Boschke, San Francisco, Cal.



In dredger, combination of wheel, dredging buckets secured on periphery thereof, wheel having annular plate, pair of friction rollers engaging sides of plate, shafts carrying rollers, bearings for shafts, transverse slideway for bearings, and means for exerting yielding pressure toward each other upon bearings.

GOLD SEPARATOR.—No. 757,205; J. W. Korfhage, Denver, Colo.



Gold separator comprising annular trough, rotary shaft on which trough is mounted, riffle plate extended upward from outer wall of trough and curved inward, screen arranged horizontally in separator and having imperforate portion extended partly across trough, and mercury containers communicating with trough or trap.

Method of Assaying Tellurides.

TO THE EDITOR:—The scorification assay of tellurides is something of the past, or should be, on account of the small sample necessarily used and the inaccuracies due to volatilization of values. The following crucible charge has given very good results on telluride ores running in value from $5 to $400 per ton:

Ore	½ A. T.
Sodium bicarbonate	½ A. T.
Litharge	3 to 4 A. T.
Borax glass	10 gms.
Reducing agent	Sufficient to give 20 gm. button.

The fusion to be run at a low heat, this being made possible by the large amount of litharge used, which gives a very fusible charge.

The large quantity of litharge has another advantage in that it oxidizes the tellurium, which is the trouble giving element. The amount of litharge used varies with the tellurium content of the ore.

E. J. HALL.

Columbia University, Dept. of Chemistry, New York.

W. E. PASSMORE, secretary of the Colorado Mine Operators' Association, has issued a call for their third annual meeting to be held at the Brown Palace Hotel in Denver, May 2, 1904. Election of officers and other important matters will come before the meeting.

Mining Summary.

Specially Compiled and Reported for the Mining and Scientific Press.

Geological Survey statistics just issued place the world's production of petroleum in 1902 at 185,151,089 barrels. Of this the United States and Russia produced 91 44%. For years Russia has led in production, but an increase of 19,377,722 barrels in the production of the United States in 1902 and a decreaso amounting to 4,628,515 barrels in the production of Russia caused these two countries to change places and put the United States at the head of the list. More than double the quantity of the higher grades of refined products is obtained from the average crude petroleum produced in the United States than is obtained from Russian oil. The United States produced nearly 2.6 barrels of refined products in 1902 for every barrel produced in the rest of the world.

ALASKA.

(Special Correspondence).—A San Francisco, Cal., company having placer and lode mines near Teller, 80 miles northwest of Nome, it is reported will do a large amount of development the coming season, including the construction of a 20-mile ditch to bring in water under pressure for hydraulicking. It is also the intention to develop the tin-bearing lodes owned by the company in the vicinity of American river. Fifty horses will be sent to Teller in the spring to be used in plowing on the ditch line. G. Gibson of Teller is manager.

Seattle, Wash., April 18.

Superintendent MacDonald, of the Treadwell mine at Juneau, has the pyramid representing each year's production of gold at the Treadwell about completed, says the Juneau Record. It is composed of twenty-one bricks, the first year's production (about $2000) being the small brick on top. Each brick toward the base is larger than that above to the last, which is almost 12 feet in length. The value represented by this pyramid is $22,000,000, or more than three times the purchase price of Alaska. When completed the pyramid will be packed and shipped to the St. Louis Exposition and be placed in the Alaska building.

By decision of the board of Arbitration in the matter of the title and proceeds of placer mining claim No. 9 Above, on Anvil creek, Cape Nome, N. O. Hultberg, assignee for the Swedish Evangelical Mission Covenant of America, recovers from the White Star M. Co. of Illinois, C. W. Johnson and P. H. Anderson, the mining claim in dispute and proceeds to the amount of $263,686. The case grew out of Alaska gold mines staked out by Covenant missionaries in 1898. Mr. Hultberg staked the first claim for his society, and when he returned to the States Mr. Anderson and others continued the work. They declared, however, that the mines were their property, not the mission society's. Not wishing to have the church organization appear as a litigant in court, private arbitration was decided on, the hearings beginning in secret February 28. Two of the disputed claims were at one time held by Eskimos, and this necessitated the presence in Chicago of Gabriel and Constantine Uparaczuck, natives of Alaska. A number of other witnesses were brought to Chicago from Alaska. The ownership of mine No. 9 was the only one passed on by the arbitrators. The opinion of Arbitrators Gilbert and Lane recites that "Anderson himself did not either directly or indirectly make any contribution, either by way of labor or money, toward the acquisition of the title to the claim in question. He never saw it until some time after the legal title to it became vested in him."

ARIZONA.

Cochise County.

The three furnaces of the Copper Queen Co. at Douglas are about to be blown in, says the Bisbee Miner.

The Spray is putting in foundations for a new "dinkey" on the spot formerly occupied by the old geared hoist.

Preparations are in progress at the Gardner, where the foundation for the new hoist is completed. The collar of the shaft will be elevated several feet to bring it up even with the floor of the hoist. The engine will be the finest and most powerful hoist in Arizona.

Maricopa County.

(Special Correspondence).—R. H. Laudermilk, near Agua Caliente, has a shaft down 72 feet and a drift in 28 feet. The ledge is 5 feet in width and the ore is free milling. Value of ore is $20 per ton.

J. V. Creath is making preparations to resume work on his claims in the Phœnix mountains. Work will be continued for a year, when a cyanide plant will be installed.

The Gila Gold Lode Co. are working men on their property in the White Tank mountains, north of Buckeye. The ore is free milling, and when the property is developed further, a mill will be built.

A number of properties in the vicinity of Cave Creek are being worked. A. S. Mills is developing a promising copper property; E. Howard is working on a gold property and W. Channel is working on a gold property in the vicinity of Cave Creek.

The Wickenburg smelter, which changed hands some time ago, will be blown in on April 20th, as a sufficient quantity of ore, fuel and flux have been obtained for a continued run.

Phœnix, Ariz., April 11.

(Special Correspondence).—A. Ford has left Phœnix for the Eagle Tail mountains to work on a copper-gold property.

W. H. Black and J. S. Spencer are working on a gold property east of Morristown, which they located some weeks ago.

Morristown, April 18.

Mohave County.

Randall & Forden closed an option on the Billy Mack mine for $51,000. The first payment on the property was forwarded to W. H. Mack and the purchasers have taken possession of the property. The Mack mine is on the Arizona side of the Colorado river near Empire Flats, 50 miles below The Needles. Mack is reported to have taken out a large quantity of rich ore. Single-handed and alone he sunk the shaft to a depth of 300 feet and exposed a large body of free-gold ore. For years he has refused to sell or work his property. Mack gave several options on the property at various times. Randall & Forden say they have bought the property for themselves and intend to develop it systematically with modern machinery. They are also interested with T. M. Drennan in the Colonel Davis and Osborne group of claims in that district, and it is their purpose to erect a custom smelter.

Yavapai County.

(Special Correspondence).—The Black Canyon C. Co. have disposed of their entire holdings in this county to a new corporation known as the American Mineral Exploration Co.

Mayer, April 18.

(Special Correspondence).—F. Williams is securing patent to several mining claims on Mount Union known as the Storm Cloud group. The property consists of 208 acres, in which there are several veins which have been developed by shafts and tunnels. The property adjoins the Cash mine on one side and the Senator property on the other. The ore contains gold, silver, copper, zinc and lead.

Prescott, April 18.

The Pittsburg-Jerome C. Co. will develop a group of mines near Jerome which they have recently bought of G. Avery and J. Larsen, who will have charge of the development work for the company.

At the Iron King mine at Blanchard a large number of men are at work at the mill installing the stamps, says the Miner. The new stamps weigh 1300 pounds each. The mill has been running steadily for several weeks and the results attained have been satisfactory. The plant has been hampered for tank capacity. Men are at work putting together the six steel tanks, which will have a capacity of sixty tons each. This will give the cyaniding plant a capacity of nearly 800 tons and will allow the mill to run full capacity day and night. It is expected to have the new stamps and the new tanks ready by May 1st. From 50 to 100 miners are to be put on in May.

F. M. Sentenney, of Prescott, is reported to have struck a ledge on Wolf creek, 8 miles south of Prescott, with both walls of porphyry. The ore runs $600 per ton. It is a new discovery and only a few feet have been cut into from the bottom of the gulch. The vein crosses the Benedict ledge, from which rich ore was shipped out years before railroads were built in this section.

Two large boilers are being put in by the Arizona-Michigan M. Co. in the Hassayampa district, south of Prescott. E. E. Greenwood is in charge.

D. M. Timmons, of Prescott, has commenced work on the properties of the Gold King Co. in Bradshaw mountains.

Stratton & Son have begun work on their property on Lynx creek, south of the Hudson.——Lucase & Fields are sinking on their claims on Lynx creek and have two shafts down 130 feet and one tunnel in 235 feet in ore. Assays average $15 in gold to the ton, with copper and lead.——F. Giger has struck a 12-inch vein on Lynx creek, says the Courier, that shows ore running well in gold and 10% to 20% copper. This property is north and joining the Hudson group. Considerable placer gold is being washed out daily on Lynx creek.

Yuma County.

Hodges Bros. have sold their mining claims, in Hodges district, 60 miles up the river from Yuma, says the Sentinel. G. Hodges retains his interest and is a member of the new company, which has been incorporated as the American Flag G. M. Co. A stamp mill will soon be on the ground.

CALIFORNIA.

Amador County.

At the Fremont Con., near Amador City, forty stamps are dropping steadily. The ore is said to be good grade. It is mostly coming from the foot wall vein in the Fremont. At the Bunker Hill, south of the Fremont, twenty stamps are running. The ore reserves are being increased by development.

Butte County.

(Special Correspondence).—On March 31st the latest dredger built by the Risdon Iron Works for J. H. Loggett of Oroville began work. The buckets are of 5 cubic feet each; the dredger will dig 35 feet below the water level and stack the tailings 30 feet above; it has a monthly capacity of 60,000 yards, bank measurement. There are five Westinghouse electric motors on board, taking a 3-phase current at 500 volts, the current being brought on board at 4000 in —Y— and transformed to 500 in delta. The main bucket line is driven by a variable speed motor of 75 H. P.; the main pumps are direct connected to 50 H. P. constant speed type C motor, one pump delivering a high-pressure supply into the screen and the other a low-pressure supply on to the tables. The main winch is driven by a 15 H. P. variable speed motor. This winch is of the Risdon design, but with heavier head line shaft and large brake surfaces. It consists of four side line barrels, each operated by friction clutch, one head line barrel operated by jaw clutch, and one derrick line barrel, also operated by jaw clutch. All the levers are brought to a convenient platform, so that the winchman has all the levers close to his hand. The ladder winch is self-contained and operated by a 20 H. P. variable speed motor; this winch raises and lowers the ladder independently of the main winch. The revolving screen or trommel is driven by a constant speed 10 H. P. motor. This trommel is made so that any part is renewable and is fitted inside with spiral steel bars and special jets in the spray pipe to disintegrate the material passing through it. The elevator is driven by a 10 H. P. constant speed motor. This motor is placed close to the top of the elevator. The whole of the machinery is erected on a substantial hull, 90 feet long, 30 feet wide by 7 feet deep, and is housed over.

Oroville, April 18.

Calaveras County.

(Special Correspondence).—At Mokelumne Hill several rich finds are reported in the ancient river beds which underlie the village. In early days the channels were worked vigorously with rich returns. There are several of these channels on either side of the town and some of these run under the principal streets and buildings. In early days the claims were small —16 feet square at one time—too small to be worked to advantage where shafts had to be sunk. In most instances a number of these claims were consolidated by the several owners and the consolidation worked as a single claim. In the haste to work out the ground in a few instances fragments of ground were overlooked or a pay streak was lost by being cut out by a later channel, and it is on one of these latter that the new find was recently made. It has resulted in a revival of prospecting on many lots and long abandoned claims. The ancient rivers are covered with volcanic debris, mostly tuff, to a depth ranging from 20 to over 250 feet. Further down Stockton ridge to the westward of the town the deep channels have been worked by means of tunnels. On the top of the ridge are circular shafts sunk in 1850. They are 250 feet in depth and have not a stick of timber from top to bottom and never had. The shafts are open from top to water level, which is near hedrock.

Mokelumne Hill, April 18.

It is reported that good ore has been struck in the Red Gold mine, near Murphys.

A pocket of gold was found on German hill, 4 miles north of Angels a few days since, by a man who has been working there for three weeks. The amount taken out is stated to be $8000, and was found a few feet below the surface. The man who found the pocket worked around here years ago. A short time ago he returned and went to the owner of the ground and told him he knew where there was a pocket and offered to work it. He secured permission, he gave to the owner 10%, and the results show that his judgment was not at fault. He is now at work searching for another pocket.

The Metropolitan G. M. Co. has been organized to operate the Jones mine (Carson Creek mine), which was recently bonded by T. Kerns and J. A. Cameron of Spokane, Wash., who transferred one-third interest to Walters & Mausner of Spokane, says the Angels Record. Mr. Walters said, while looking over the Allison and Carson Creek properties, that he had never seen a better outlook on Carson creek, but owing to the bad condition of the mill the company is compelled to close down for repairs. J. A. Cameron is in full charge.

Inyo County.

S. R. Phail of Snow's canyon says that the Golden Argus mine, near Ballarat, will start up soon. J. Cyty has out a large amount of high-grade ore and is running his mill. J. C. Cross is also running on ore from his mine. Mr. Phail has had four runs of ore in the Golden Argus mill from his mines.

Kern County.

The Minnehaha has had ore treated at Snow's mill.——Jones & Sumers, leasing on the King Solomon, have had a crushing.——The Red Dog mill is milling ore from White's camp.——The Red Rock G. M. Co. have a well drillor on their property in Red Rock canyon, says the Randsburg Miner, and will prospect the ground under the direction of J. A. Atkins.

Atkinson Bros., operating the Sunshine mine, near Randsburg, have commenced milling. Development work in this mine has opened it up to such an extent that the operators are contemplating installing compressed air drills and a steam hoist.

Including the 1,000,000 barrel reservoir to be built by the Associated Oil Co., says the Oil Reporter, it is estimated that the reservoirs planned and being built will add 2,500,000 barrels storage to the present private storage in the Kern field. Whether the different companies will store their oil in these reservoirs or sell, will depend on the price that can be obtained for oil during the next six months. If the prices range 20 cents or better it is likely all the oil produced will be sold at once; if less than this figure, the oil will be stored for a better market.

Los Angeles County.

The known extent of the Los Angeles oil field is being extended by drilling bore holes in the area west of the city of Los Angeles. There is said to be a probability of finding good oil territory in that direction. The monthly output of oil for the Los Angeles district is increasing.

In the Whittier oil field the Oil Reporter thus summarizes the situation:

Wells drilling	16
Wells suspended	0
Wells pumping	80
Wells abandoned	0
Wells completed	0

Twenty acres of oil land near Whittier were recently bought by the Home Oil Co. for $400 per acre. A well will be sunk on this tract.

Madera County.

(Special Correspondence).—The work of repairing the Gambetta shaft at Grub Gulch is completed. It is reported that a long drift is to be run from one of the lower levels toward the Josephine vein, also owned by the company, as it is thought a large ore body will be found there. The Josephine vein is on or near a contact of granite and slate, and the Gambetta is a fissure cutting slates and schists in both strike and dip. The Gambetta vein, though smaller than the Josephine, is rich. A characteristic is the occurrence of arsenical iron sulphide rich in gold, both free and combined. The mill, it is expected, will be able to treat 100 tons of ore daily.

At the Texas Flat mine, near Coarse Gold, the new 20-stamp mill is treating four tons per stamp daily. The ore is granular quartz, carrying gold and auriferous pyrite.

Near Fresno river are several veins in the Grub Gulch district, which cut the formation and in some instances are accompanied by aplite or granite dikes. These veins resemble the Gambetta and carry arsenical pyrite, some of which is rich in gold. Thus far not much development work has been done on these veins.

Grub Gulch, April 18.

Mono County.

The Lundy Cyanide & Development Co. intend digging a canal to drain the upper end of Lundy Lake this spring, says the Yerington, Nev., Times. This will lay bare the tailings now beneath the water, and they will be worked. The trench will be about a quarter of a mile in length.

Nevada County.

It is reported at Grass Valley that the Idaho-Maryland mine is to be reopened. Mr. Dorsey, the owner, who is negotiating with the Eastern men, says that nothing

definite will be known until Mr. Wilkins returns to Boston. It is thought the deal will be made and that the mine will be pumped out for examination. There remains much undeveloped territory in the lower workings, and there are known to be parallel veins carrying good gold values. The main shoot produced $25,000,000 from the surface to the present bottom of the mine. When the ore shoot pinched out little development work was done, and the mine was closed and has since filled with water. If the property is reopened it is expected a new vertical shaft will be sunk near the present south limits of the ore body.

Mr. Rosenfeld of San Francisco, who recently bought the Lamarque and Inkerman mines, near Grass Valley, says a double-compartment shaft will be sunk. The site for the shaft is about 1000 feet from the west line of the Lamarque, almost on the lode line, and the prospect shaft at that point taps a strong ledge of promising appearance, 1 foot in width. This is some distance back of the old workings, which have been ascertained to have been off the main ledge. Orders have already been placed for machinery. Cornish pumps will be used. A 6-drill compressor is to be installed, with hoisting and pumping plant. Work on the buildings to house the machinery has commenced. C. Brockington is superintendent. The mines are 2 miles south of Grass Valley. The vein has a low dip—about 18°—between slate walls. The sulphurets are high grade. The Lamarque has been developed to a depth of about 350 feet.

Superintendent Graham of the Shady Creek placers reports that in two weeks he will have things running full blast. A string of flume and pipe line is being constructed which will furnish water for the elevator.——At the Brophy claim Superintendent Miller is installing a centrifugal pump.

Placer County.

R. Jeffrey, a few days ago at the Gold Blossom mine, near Grass Valley, put in a blast after clearing out debris. The shot was fired and broke into a pocket of specimen ore. The mine had been idle for some time.

Plumas County.

W. H. Corbiere has bonded the quartz mine owned by J. Freeborough, of Poker Flat. From this mine Mr. Freeborough has taken out several thousand dollars with a hand mortar. The ledge is large.

San Diego County.

(Special Correspondence). — C. W. Pauly has been allowed $500 per month as receiver of the Free Gold M. Co., S. M. Shortridge of San Francisco has been allowed $14,500 for legal services by Judge Torrance of San Diego, and J. Chandler was also allowed $15,000 for similar services. Some of the stockholders object and will petition the State Supreme Court for stay of proceedings.

Picacho, April 16.

An oil well is being drilled at Chula Vista, southeast of San Diego. It is expected that sand and clay will be found until 600 feet is reached, when gas or oil may be found. Holes, sunk some time ago, developed gas at from 400 to 600 feet. The depth of the deepest was 700 feet. The intention of the present enterprise is to go down 1500 feet.

The Encinitas copper mine, 18 miles north of San Diego, which is being developed, demonstrates the existence of good copper ore in large quantities in this section. Superintendent H. MacKinnon says: There is one 400-foot shaft, another 225 feet, and a third 180 feet; with three 100-foot drifts and two 50-foot drifts. The work of sinking, drifting and stoping is going on. The mine is equipped with ore crusher, 6-foot mill and two concentrators. The power is supplied by three large gasoline engines. Two hundred and fifty tons of ore have been milled. The water pumped from the mine is used for milling purposes.

Shasta County.

It is reported that the Midas M. Co. at Harrison Gulch will resume work in the Midas mine. The Midas employs 100 men when in operation. A lockout occurred on February 19th last, since which only two watchmen have been employed. The lockout affected both union and non-union men. The Miners' Union has maintained its organization during the lockout, but it is understood that when the mine opens up it will be with non-union men, who will be brought in from the outside.

Sierra County.

(Special Correspondence).—The Sierra Buttes mine is reported sold to Hayes Bros. of San Jose, Cal., togother with the Butte Saddle and the Bigelow mines adjoining. It is proposed to work the group through the Sierra Buttes tunnels which hold the topographical key to the situation. The Sierra Buttes mines were worked extensively and profitably for years under English ownership. It is believed that under improved modern methods these mines will now again become profitable. W. D. Pinkston is superintendent. At present there is 12 feet of snow at the mines. The surrounding county is very rugged and the difficulties of transportation are numerous, but the property is equipped with machinery which only requires overhauling. Development will begin as soon as practicable.

It is also reported that R. J. Anderson has bought the Hilda and Klondike drift mines, near Sierra City, which property will be consolidated and worked by the Pliocene M. Co. of San Francisco, Cal.

Sierra City, April 18.

It is reported that negotiations for the purchase of the Maple Grove drift mine, between Alleghany and Forest City, are pending. The claim contains 2000 feet of the lowest known part of the Ruby channel, which has yielded $500,000. One nugget from this place sold for $3000. If the Maple Grove is taken over, a tunnel will be started above Cumberland to work the channel.

Siskiyou County.

J. Johnston of Yreka has made arrangements for working the Headwaters quartz mines on Humbug creek, with intention of putting up a smelter, near Yreka.

A. C. Brokaw of Yreka found a $30 nugget with a little quartz attached, while piping down the bank. His hydraulic claim in Quartz valley is one of the most extensive in the State. He intends laying pipe in another year for a distance of a mile, in saving several miles of ditch, and gain 400 feet pressure for the hydraulic elevators and giants. This change will also save a great amouut of water.

J. B. Scott reports doing well at the New York quartz mine on Indian creek. A. C. Brokaw has the extension of the New York mine, known as the Golden Eagle, which shows rich quartz, with ledge 4 feet wide. He intends putting up a mill at the mine during the summer.

The Wright & Fletcher hydraulic mine at Oro Fino has been kept in steady operation all winter with an abundance of water. While other mines in the vicinity suffered damage from the heavy storms, this claim escaped threatened danger from the waters.

It is said the management of the Carlock & Morrison mine of Quartz valley is going to install new machinery, consisting of air compressor, five stamps to the mill, making in all ten stamps, and machine drills.

L. Hill and B. Carter have begun to open up their property on Eddy's gulch, adjacent to the Ball mine.

Trinity County.

A rich gold strike is reported made in Ferry gulch by E. B. Channel, of Minersville, and his partner, A. S. Thomas, who after prospecting a few days uncovered a rich body of ore, 2 miles east of the Fairview mine. During the first day they mortared out $400 in gold in a hand mortar. Tracing their ledge up the mountain they uncovered another pocket from which they mortared out $400 more. Ferry gulch has been mined for fifty years.

Tuolumne County.

(Special Correspondence).—The Mount Jefferson mill at Groveland is to resume crushing, it having been idle pending development work.——At Big Oak Flat the Moody mine has been unwatered for investigation.——The custom mill on Big creek, east of Groveland, is running on ore from various mines of the vicinity. The Cosmopolite mine on Cosmopolite hill, between Big Oak Flat and Groveland, is being unwatered. This mine has been extensively worked and has produced a large amount of gold, mostly from pockets. In the vicinity of Groveland, Big Oak Flat and Priests considerable prospecting is going on with encouraging results. There are a number of pocket claims near Big Oak Flat and Priests, which seem to warrant more systematic development, as the indications are that the gold-bearing zone will pay to mill, as a whole, as is done at the Jumper, near Stent.

Big Oak Flat, April 18.

Connally & Summers have been milling ore from the Side Wiper mine, near Arrastraville, in the Pennsylvania mill at Cherokee Flat.——It is reported that the Soulshy mine is to add five stamps to the mill at Soulsbyville. —— The Seminole mine, 1 mile southwest of Tuolumne, has been unwatered for examination and it is reported an ore shoot 100 feet long has been found which carries a good percentage of high-grade sulphurets. The vein is 3 to 6 feet wide. The mine is equipped with machinery.

At the Black Oak mine, near Soulshyville, forty stamps are again dropping, and the plant is in full operation.

Forty-eight mining companies of Tuolumne county have contributed to the display to be made at the World's Fair at St. Louis, says the Sonora Union-Democrat.——It is reported the Harvard mine at Whisky Hill, near Jamestown, will resume work in May.——It is said the Golden Gate mine, near Sonora, will be worked under new owners. The property has been idle the past year. The Golden Gate is down 700 feet.

Yuba County.

Bids for the construction of a pile and concrete harrier on the Yuha river will be opened hy the California Debris Commission at San Francisco, Cal., May 4th. The work will be hegun within thirty days after the bids are accepted by the War Department at Washington.

COLORADO.

(Special Correspondence). — Business conditions throughout the State are improving. Good strikes continue to he reported from several mining camps, which is encouraging. Articles of incorporation have recently hsen filed with the Secretary of State of the Gray's Peak Railroad Co. It is the intention of this company to build an electric line from Silver Plume, in Clear Creek county, around the slope of Leavenworth mountain into East Argentine mining district, for the purpose of hauling ore, as well as passengers.

Denver, April 18.

Boulder County.

The Terror mine, on Spencer mountain, has been bonded and leased from the Terror M. & M. Co. by W. M. Williams of Boulder, vice-president of the Jenny Creek M. & M. Co. The Terror has 1000 feet of development work done and in all of its workings large bodies of low-grade ore are found. It is equipped with hoist and station and sinking pumps, and as soon as unwatered drifting will hegin.

The United States G. Co. is driving its tunnel into Arapahoe mountain to cut the Monroe, Arapahoe and Klondyke veins. One vein has been cut with assays reported of $65 per ton. The vein has no surface indications.

H. H. Mund, of Denver, has started work on the Caribou silver mine. For the present work will be confined between the tunnel level and the surface, opening new territory that had not been explored by the old company. The tunnel level is 300 feet helow the surface. Should he he successful, he will make arrangements with the company to unwater the lower workings. Caribou was once the largest city in Boulder county, and the mines produced more ore from 1870 to 1880 than all the mining districts in the county. It is believed that the mines of Caribou district, if properly developed, can be made to pay even at the present low price of silver.

Clear Creek County.

The Clift property, on Democrat mountain, at Georgetown, has been sold to the Saxon Mountain M. Co., says the Courier, for $15,000. The Clift in recent years has produced $120,000. It has been owned for a number of years by A. Ford and associates, hut of late hut little work has been done. The Clift is surrounded hy producers, among them the Fred Rogers, Government, Junction, Little Emma, Polar Star and Silver Glance. The Clift is supposed to be an extension of the Silver Glance, which has been a heavy producer. The upper level has been driven 75 feet, and it is thought by driving another 100 feet the veins of the Silver Glance and Rogers will he cut. Level No. 2 is in 700 feet. Level No. 3 has been driven 500 feet. No. 4 is in 706 feet. This level will have to be driven ahead some distance hefore the main ore hody is reached. The lower level is in 800 feet, but no stoping was ever done. There is a large body of quartz in the hreast, carrying an occasional streak of high-grade ore. It is the intention of the company to drive the lower level ahead. The Saxon Mountain M. Co. own a group of claims on Saxon mountain and the Clift has been consolidated with these holdings. The offices of the company are in St. Paul, Minn. D. W. Shepard of Georgetown is manager.

Arrangements have been completed for heginning work on the railway to he built by the Hazleton Con. Co. This road will be 5 miles long and is for the purpose of transporting ore from the Santiago mine to the mouth of the Baltimore tunnel above Silver Plume. It is the intention to build a mill of large capacity, says Manager Rogers.

N. Gregg of the Gregg Investment Co. of Denver states that work will he under way on the tramway in a few weeks.

Good reports come from the Vidler tunnel, heing driven by the Transcontinental M. Co., says the Georgetown Courier. It is expected a vein will he cut in a few days. The tunnel, when completed, will be utilized for railroad purposes as well as for mining. With the machinery in operation which will be installed shortly, the Vidler tunnel will make more rapid headway.

A 4-foot vein carrying streaks of gold, copper and silver was cut in the Grass Valley tunnel on Soda creek this week, says the Denver News. The hreast of the tunnel is in 120 feet, and nearing the Gomez vein. The property is in the control of the Rocky Mountain Securities Co. of Denver and the work is being done hy contract by W. B. Lowery.

The Chicago Mountain M. & T. Co.'s Three Friends tunnel, near Idaho Springs, is being driven under contract hy E. A. Adams. There is now about 3 feet of low-grade ore in the tunnel and they are nearing the junction of the Three Friends vein, which will be cut at a depth of 200 feet.

W. A. Slater, E. S. Giles and E. L. Clarke have organized the Lincoln Co-operative M. & L. Co., which will operate the Muldoon group in Lincoln district. The company has a limited number of members, who each pay into the treasury $10 per month for the purpose of carrying on the development work. They are developing the group by a tunnel and will soon begin shipping to the Bertha mill.

Work is to hegin within a few days on the South Africa claim, in the Freeland section. The claim is the east extension of the Old Stag, and is owned by New York and Montreal parties. It has three veins showing within the side lines, and the shaft is on the center vein. This shaft is down 30 feet and will be sunk to 100 feet, the crosscuts run thence to the other veins. In the hottom of the shaft at present there is from 4 to 5 feet of concentration material of a fair grade.

Indications are that the Yankee, near Idaho Springs, will be producing as soon as the season opens up. The Yankee Con. M., M. & T. Co. is getting ready to start up its new Lombard mill. The mill was finished last fall, but the country was frozen up before it could be started. This mill has a capacity of seventy-five tons per day. H. I. Seemann is president and general manager of the company.

Work on the Central Colorado mine, near Silver Plume, is being prosecuted vigorously, under direction of W. Blantou. Several lodes have recently heen cut by the tunnel, and a shipment of three carloads to Denver brought good returns. This company has been developing this group for a number of years.

The Terrible mill at Silver Plume, which has been idle for eight weeks owing to the pipe line being frozen, is again running. Five machine drills are at work on the different levels on development. Two more drills will be added. Forty men are employed. The creek now has plenty of water for power, and it is possible that no further trouble will be experienced on the pipe line. Two shifts are employed at present and the force will he douhled hefore the first of May. Tbe mill has a capacity of 100 tons of ore daily. In 1870 the Terrible L. M. Co. shipped 99¾ tons of ore to England, which returned $52,462, and 300 tons of ore from the Brown lode, treated at the Brown mill, gave returns of $115,822.60. These two lodes were the largest producers in Clear Creek county in that year.

Fremont County.

The Blaney Oil & Gas Co. have completed the first derrick and have commenced drilling. The well is a few hundred feet from the heaviest producer of the Frazier Oil & Gas Co.——The Victor Oil & Gas Co. has spudded to drill well No. 3 on its leased ground south of Florence.——The first derrick of the National Oil Co. is completed and drilling operations will hegin in a few days. While excavating for the foundation timhers a petrified tree 10 feet long and 18 inches thick was unearthed.

Gilpin County.

The Penohscot M. & M. Co., near Central City, is reported to have struck good ore in the Penobscot tunnel in Gamhle gulch, in Independent district. The tunnel is in 1045 feet and another contract for 100 feet is to he let. The breast shows 5 feet of mineral, of which 18 inches is smelting ore, carrying gold, silver, copper and lead, the balance heing concentrating ore. The company is considering the huilding of a mill. P. J. Hamble is manager.

A steel cahle 1500 feet long has been put on by the Mackey-Burroughs mine on Quartz hill during the past week. Sinking is in progress and this lift of 100 feet will put the shaft down 1000 feet.

The Jenny Creek M. & M. Co., operating in Jenny creek section of the Kansas district, has let another contract for 250 feet on its tunnel to A. E. and W. Scoville, C. Tavaner and E. Miller, and the contractors are reported making good headway.

Operations have been suspended temporarily at the Pleasant View mine on Gunnell hill, near Central City, owing to had air and difficulties in operating through the St. Louis-Gunnell shaft, and it has been decided to sink a new shaft west of the Pleasant View shaft, erect new shaft building and install a plant of

machinery. The Mutual Benefit Co. are owners. W. C. Carnegie is in charge.

Judge Do France has issued an injunction restraining the Roderick Dhu G. M. Co. from taking ore from the Wheal Zor lode. Both mines are in the Nevadaville district, this county.

Tippett & Co., working the Forks mine on Quartz hill under lease, made a shipment of six cords to the Randolph mill during the past week.

Manager J. Lillig of the Golden Rod M. & M. Co., operating in Silver creek, reports that they have reached a depth of 115 feet in the Pet shaft and have opened smelting ore which carries good values.

Leasers on the Speeio Payment mine on Bellevue mountain have shipped a carload of smelting ore from the Black Hawk depot to the Argo plant.

The Gower Mines Syndicate, Ltd., have shipped three cars of concentrating ore from the Running Lode mine to the Alpine mill on South Clear creek.

Richards & Co., leasing on the Old Town mine in Russell district, shipped a car of ore to the Argo smelters last week.

Gunnison County.

The Kimberly group of six claims, between Camps Sherrod and Bowerman on the middle fork of Quartz creek, near Pitkin, is being operated by the Monarch M., M. & Dev. Co., says the Pitkin Miner. The workings consist of an incline 160 feet showing a 2½-foot vein, which has been driven over a hundred feet. An 80-foot tunnel has been driven and an 18-inch vein cut at the breast. The walls are granite and lime and the mineral carries values in gold, silver and lead. There are three carloads of ore on the dump ready for shipment that average $30 per ton. The company contemplates starting a new 500-foot tunnel lower. Manager Givens has sixty acres of placer ground in the gulch that has been platted into town lots and that locality will be known as Camp Givens.

In Mineral Farm basin the Citizens and Maid of Athens have several ore teams on the road hauling ore for shipment. There are a few hundred tons of mineral in their bins which runs from $35 to $100 per ton in gold, silver and lead. The stopes in these mines are looking well. The sulphides carry a good percentage of lead. During the past month or two the Citizens was bothered with water in their shaft, but at present two hours of hoisting per day keeps the mine in good condition.

Samples of ore from a mine recently opened on Pomeroy mountain, near Hancock, assay very high in gold. The mine is near the Alpine tunnel, 13,245 feet above sea level. The ore shows free gold and wire gold, visible to the naked eye, and the mill runs of the free-milling ore are said to he over $300 to the ton.

It is reported that the first shipment of ore from the Camp Bird mine at Bowerman, owned hy Hurley, McShane & Short, has been attached at Pueblo on account of adverse claim of ownership of the property by the Goodwin T. Co.

Development work continues on the North and South Hall's gulch tunnels of the Colorado S. & M. Co. Air drills are used and the tunnels are in between 600 and 700 feet each. These workings will open up the contacts of the Silent Friend and Mineral Farm basin sections.

The Independent G. M. Co., operating the Bowerman group in the Box Canon district, has started a new tunnel between the shaft and lower tunnel. This new workings will be driven on the vein which will be more economical than working on the rich ore by drift in the shaft.

The Iowa Con. M. Co. has been incorporated by F. T. Voris, C. A. Berger, A. W. Hall, A. W. Unger and A. Koehler. The company is operating at the Iowa group of claims in Bertha gulch, Tin Cup district.

G. A. Dewey has begun operations on the Copper King in Box Canon district and will push development work on the property throughout the summer.

Lake County.

(Special Correspondence).—The mineral output of Leadville, after a continuous period of prosperity extending over twenty-six years, still holds its own, but the output would be still greater were treatment charges lower. A number of companies and individuals, owning or controlling large tracts of mineral lands, will neither work the property themselves nor lease to others unless they receive exorbitant royalty. Were this condition different, the output would be materially increased.

In the down-town district considerable activity is manifest among the different properties. The Western M. Co. is operating the Midas, Coronado, Adams and other properties. This company is also running the Adams mill, which is producing 3000 tons of concentrates per month. The ore comes from the Adams shaft, on Carbonate hill. On the Henriotta the Western Co. has recently erected a new shaft house and trestle. Under this trestle ten 50-ton cars can be placed. Both of these properties have been large producers in the past. The Coronado is being worked at present and it is expected the Henrietta will start up later.

Below the Adams mill, in Stray Horse gulch, C. Delker has a small plant treating tailings from the Adams mill. In this mill he has a magnetic separator and other devices of his own conception.

The Caribou Leasing Co. is shipping 100 tons of ore per day to the Salida smelter. This company has recently erected a new head frame over the Wild Cat shaft, which is now down 100 feet, and will take the place of the old Caribou shaft through which they are now working. There is a large body of ore in the Wild Cat.

In California gulch is the California Gulch M. Co.'s property, which is being worked by leasers. They have found some good ore, but not yet in paying quantities.

The A. Y. & Minnie mill is being operated by the Great Western M. Co. This mill is producing about 1000 tons of lead concentrates per month. Just above the mill are the buildings of the Minnie mine.

Across the gulch from the Minnie is the Gilt Edge shaft, operated by the New Leadville G. M. & M. Co., T. S. O'Brien manager. This company is employing twenty-five men and averaging thirty tons of ore per day. The ore is lead and zinc sulphides. The shaft is 500 feet deep. The property is equipped with 200 H. P. boiler, 125 H. P. hoist, 2-drill compressor, 300-gallon compound pump. The ore bins, which are located on the Colorado Midland Railway, have a capacity of 500 tons. The company will increase their boiler capacity later.

A little farther down the gulch is the Moyer property, owned and operated by the Iron Silver M. Co. This company is shipping 10,000 tons of ore per month and is said to he the heaviest shipper in the district. The new ore bins have a capacity of 1500 tons. The building is 82 feet long, 26 feet wide and 55 feet high. The bottom of the ore bins is made of railroad iron. About 30,000 pounds of iron and steel have been used in the construction of the building, besides 125,000 feet of lumber. On this mine they have a 482 H. P. double-drum, counter-halanced hoist, an 8-drill air compressor and boilers.

Leadville, April 15.

San Juan County.

T. J. Hurley of the Ruby Basin M. Co. of Silverton says a new mill will he ordered this month.

C. Dale, contractor, is placing the machinery in the auxiliary mill of the Gold King, near Silverton. Excavations have commenced for foundation of the new power house and for the auxiliary concentrating plant. There are to he installed two marine boilers. It is expected to have the auxiliary mill completed and running by Sept. 1. Concentrate product from the Gold King shipped over the S. G. & N. railroad aggregates 100 tons daily.

In Prospect hasin, near Silverton, the force on the Henrietta mine comprises twenty-five men. Following the blowing in of the smelter the force is to be increased, and before fall will be close to 100 men. —— The Stony Pass M. Co.'s Mammoth tunnel is being pushed ahead. The original size of the tunnel, which was 7x8 in the clear, has been cut down and the 2x4-foot drain discarded. The tunnel is to unwater the Yankee Girl mine at Red Mountain, 2½ miles distant, and has been in operation three years. It is in 475 feet. At 5000 feet from present face it will intersect the Henrietta.

F. Wetzel has started work on his Del Mino group, foot of Prospect basin. There are nine claims in the group, the Del Mino proper being low-grade gold quartz, while the Boycotter and Boycotter Extension show bodies of copper-iron sulphides, which carry gold-silver-copper values of from $11 to $35 per ton.

San Miguel County.

The Mayflower mine in Gray's basin, a tributary of Bridal Veil, has been under development throughout the winter with good results, says the Telluride Journal. The shaft is down 450 feet and shows 4 to 5 feet of ore in which free gold is seen. The third level at 300 feet is also in good ore. At this level the west drift is in 175 feet and the east drift 40 feet, and being driven ahead. The fourth level is being started at the bottom of the shaft. The drift driven in winter on the vein bas reached a depth of 450 feet and is still going forward in 4 feet of ore. There are 5000 tons of ore on the dumps. The company has taken a lease on the Philadelphia mill at the head of Bridal Vail falls. A tramway will be erected connecting the Mayflower with tbe mill. The ore is free milling, says President Marquis.

The Ophir Con. M. Co. at Ophir Loop have had for the past four months as many men as could be employed to advantage on development. For a while ten of the fifty stamps in tho mill were dropping, later twenty, and now there are thirty. C. F. Somers, secretary of the company, says: "In a short time the other twenty will he put in operation. We are crushing our ore to pass a 50-mesh screen, which is considerahly finer than most mills in this district reduce their ore, consequently the fifty stamps in our mill will not dispose of as many tons of ore as the same number of stamps in other plants, but we expect to treat an average of 125 tons in twenty-four hours."

Teller County.

J. W. Hitchcock has leased the Divide claim on Tonderfoot hill. The claim adjoins the Hoosier on the south. A shaft on the property has heen sunk 235 feet. The machinery removed will be replaced by the lessee. The lease covers a period of two years, with a 20% flat royalty. The conditions include 10 feet sinking or 15 feet of drifting a month.

Over $800,000 have been distributed hy Cripple Creek mining companies since January 1, 1904. This is in excess of dividends paid for the same period in 1903. The following companies hy the first of May will have paid dividends as follows:

Portland	$360,000
Stratton's Independence	125,000
Mary McKinney	30,000
El Paso	60,000
Vindicator	33,000
Strong	25,000
C. K. & N.	15,000
Last Dollar	10,000
Lessees and others	150,000
Total	$808,000

The Portland, after the payment of $180,000 on April 15, will have paid dividends of over $5,000,000, and the company's statement shows a surplus of over $700,000 in the treasury.

At Copper mountain, in the north end of Cripple Creek district, the Metallic G. M. Co., which drove the Metallic tunnel in the north side of the mountain, is to resume operations on the south side of the mountain. The company has a lease on the Bill Nye claim, belonging to the Copper Mountain M. Co., where operations will begin. A new shaft is to be sunk and Manager R. Blanchard expects to cut the extension of the Fluorine vein on the dip. A hoist will be erected there.

It is reported the Free Coinage mine on Bull hill at Cripple Creek is ahout to be sold. This change will result from the purchase of a large block of Free Coinage stock by J. A. O. Carper. Mr. Carper has a lease on this property for five years, which requires the sinking of a new shaft 1000 feet.

A number of new ore bodies have been discovered on the Vindicator on Bull hill the last few months, says the Gazette. Ore shoots have heen opened previously and followed down 1200 feet. New ore bodies have been opened in the 600, 700, 800 and 900-foot levels of the property and in various other parts of tbe company's territory. The find in the 600 level has been opened for a distance of 1000 feet, of which the screenings are returning on an average of about 3½ ounces to the ton. This is the average grade of ore opened in the new discoveries. In the 900 level the new ore is returning values of two ounces to the ton. When the strike occurred last August the management of the Vindicator pulled the pumps from the bottom of the shaft and the water rose from the 1200-foot point to the 1000-foot level and remained ever since. The water rising to this point forced the company to confine its work to that portion of the mine above the water level, with the results mentioned.

Lessee Chrisman, operating on the fifth level of the Gold Coin property at Victor, has sent out its initial shipment of twelve tons, which will return values of 1½ ounce to the ton. This shipment was made as the rock was broken. Hereafter the ore will be sorted and shipped in grades. The lessee is breaking ore on what is known as the Little Montana dike. There are ten sets of lessees now operating different portions of this property and all are reported to have ore.

A. J. Wharton, of Cripple Creek, says he will erect a 100-ton cyanide plant on his property this summer. He says that he has 35 feet of ore that assays from $3 to $15 a ton, and he is confident that he can treat it and mine it at a cost not to exceed $2 a ton.

Another shipment of sixty tons has beeu sent from tbe Julia V., on the west slope of Beacon hill. A new plant of machinery is being installed and an engine house, 28x40 feet, is also being erected. Mr. Burke says: "We had assays on 7 feet of ore running $100."

The work on the new cyanide plant on the Wild Horse, owned by the United Mines Co., is progressing rapidly. The lessees on this territory believe that the entire dump of several hundred thousand tons of ore can be bandled at a profit.

W. G. Kilpatrick, who recently secured the Acacia company's ground, under a $50,000 bond and leasc, will commence working two shifts in a few days.

Four sets of lessees are working in the main shaft of the Independence Con., or Hull City placer, and all of them are taking out ore, tho grade of which is said to he hetter than $40 a ton. A 3 foot vein on the 500-foot level runs $70 per ton.

S. Warren, superintendent of the White City G. M. Co., working the Friday, adjoining the Hoosier, on Tenderfoot hill, is getting small streaks of ore that run $780 to the ton.

IDAHO.

Boise County.

R. Winter, owner of 8 miles of placer ground on Moore's creek, beginning 6 miles from Idaho City and extending two miles beyond, has two dredgers on the creek, one of which he started on the 13th inst. and the other will be put in operation as soon as repairs have been made. The dredger now in operation is working 900 cubic yards of dirt a day. Mr. Winter says there is 6000 inches of water in the creek at present. The snow is about 2 feet deep in Atlanta, hut on the summit, 16 miles beyond Idaho City, it is fully 18 feet deep.

Idahn County.

L. Abbott, superintendent of the Belle of Thunder Mountain M. Co., says the company owns thirty-seven claims, the hest known of which are the Sunnyside and Belle of Thunder Mountain. A new shoot was opened in the latter during the winter. Drifts were run in ore over 200 feet without finding ends or sides of the ore body. Enough ore has been opened in this claim to keep a 50-stamp mill running three years. The ore averages $9 a ton. The Burr Oak tunnel, which will cut the ore bodies of a number of claims in the group, has heen driven 1200 feet. In 100 feet farther it will be in ore, at a depth of 600 feet. This company employs twenty-nine men and in a few months will have 100 on the pay roll. The lower tunnel of the Dewey is reported to be in good ore. The mill has been running all winter and bullion has been sent out regularly. About 150 men have been at Thunder Mountain during the winter. Snow at the Sunnyside is 8 feet deep, and in Pen Basin 12 feet.

At a meeting of the stockholders of the Twentieth Century M. & P. Co. of Roosevelt, Idaho, and Cleveland, Ohio, held at Cleveland, it was recently decided to put in a 10-stamp mill, says the Boise News. The mill will have to be shipped in sections so as to he packed on animals. This mill will be used until such time as a wagon road is completed, when a larger mill will be placed on the property.

Owyhee County.

J. Sullivan, who is developing his Jacob gulch property, reports having cut the vein in the Shamrock claim 300 feet from the mouth of the tunnel and has drifted 100 feet on the vein, crosscutting at intervals to ascertain the average width, which is 15 feet. Tbe average value is $15 per ton. The tunnel cuts the vein at a depth of 300 feet. There are four claims in the group, with four veins running through their entire length. A shipment last season taken from the surface of these claims netted $700.

Shnshone County.

The rush from Hamilton, Mont., to the Owl Creek gold district is in full swing, says the Butte Intermountain, and 7 feet of snow covering the heart of the district. Men are leaving here and other places near by every day for the new gold fields. A numher of New York men who left last week took along 6000 pounds of supplies, which were hauled to Mineral Hill and from there transported on toboggans to the new camp at Boulder crossing, a distance of 10 miles.

The Silver King will treat the ore from the Wyoming mine, near Wardner, which is being worked under lease by O. R. Young of Wallace, says the Press. Hauling from the mine to the mill was begun, but tbe condition of the road has prevented the transportation of large loads. About twenty tons a day are being hauled, which will be increased to forty tons when the condition of the roads improves.

At the Standard mill, at Wallace, Superintendent G. Ruggles has completed the installation of the fourteen slime tables wbich bave supplanted the canvas plant that had been in operation at the mill for a number of years. There are eight Frue vanners and six standard Wilfleys. The former were the first installed and they have been treating the slimes for some time, while the Wilfley slimers have been made ready for operation.

Washington County.

The Idaho M. Co., Ltd., organized in Buffalo, N. Y., will prosecute developments on the California group of six claims on Camp creek, about 2 miles above Landore. The officers of this new company are: C. F. Macey, president and

general manager; A. H. Beckham of Omaha, vice-president; F. Macey, treasurer; J. C. Sutherland, secretary; F. Powell, superintendent. The company will begin the erection of a boarding and bunk house, blacksmith shop, etc., and operations will be confined to sinking the shaft now down 100 feet.

Another new mill will be built in the Rapid River district this season for the Weyant Milling Co., which is operating near Pollock, says E. L. Hollingshead, manager. Mr. Hollingshead says the mines are showing up well.

The Seven Devils copper district is to be reopened, says the Weiser Signal, by F. Powell and J. C. Sutherland.

MONTANA.

Carbon County.

As a result of disagreement between the Miners' Union and officials of the Northwestern Improvement Co. at Red Lodge over the selection of a weighman, 600 men are out on strike. While the real matter at issue is not great, the miners maintain that a principle is at stake, and that their rights have been invaded. The company claims that under existing conditions they have no way of protecting themselves. The weighman, an official who weighs the coal as it comes up out of the mines, is elected by the union from among its members. The company asked that a regular employe of the company be selected, and when N. Smethurst was elected by the miners Manager Pettigrew objected to his serving and ordered him to leave. The miners refused a suggestion made by the officials that the matter be referred to the higher officials before action was taken and the strike declared. The Northwestern Improvement Co. is controlled by the Northern Pacific Railway, and the officers of that railway have been notified of the trouble.

Fergus County.

In the Judith mountains, near Lewiston, the Townsend M. Co., of which L. H. Mershon is president, owns the Big Horn mine. The Big Horn tunnel is being driven into the northern base of Crystal mountain and is in 300 feet, and has cut a vein of ore 40 feet in width which carries values in gold, and it is estimated that there is enough ore now in sight to justify the erection of a mill. The ore is one adapted to treatment by the cyanide process.

Flathead County.

Operations at the Snowshoe mine are well under way, says the Libby News. Twelve carpenters are making the necessary alterations and additions to the mill, getting ready for the additional machinery which will be installed. There are two carloads of additional machinery for the mill. This car consisted of a Huntington mill, a crusher, much larger than the old one, and a compressed air receiver. The latter will be placed in the 200 level of the mine and from this the air drills will be supplied. With the proposed additions the management anticipates a large increase in production.

Granite County.

The Heverin-Houle M. Co. is moving a 56-ton steam shovel from Bearmouth to its properties on Harvey creek. The shovel grades its own way up the gulch, the track on which it runs being moved forward as the machine progresses. Two and a half miles were covered in the first two weeks, and within a week or more it will reach its destination.

Jefferson County.

Men have been at work on the Rose Gold properties at the head of Golconda creek, near Jefferson City, all winter and a large amount of ore has been extracted. The crosscut is still being run across the large vein of the Yellow Jacket, and it is said that the vein is solid ore for 95 feet. The company is preparing to erect a large mill the coming season, using electric power from the lines of the Missouri River P. Co., which runs near the property.

The Copper Mountain & Milling Co. owns forty claims in the Wickes-Corbin district, upon which development work has been progressing for several months, says the Basin Progress.

J. H. McCabe of Corbin has started work on the Robert Emmet group, 6 miles north of Boulder. The group has been a large producer of high-grade silver ore, which was shipped by ox team and river to Swansea, Wales, for treatment. The old shaft has been retimbered and the property will be developed. It has only been worked to a depth of 200 feet. The shaft will be sunk another 100 feet.

Mulvahill & Ely have put a number of men at work to develop the Daly properties at Wickes, which they have bonded. The shaft is down 350 feet and will be sunk to 500, with levels each 100 feet. They have a large amount of good ore on the dump.

The development work commenced recently at the Big Indian, in the northern part of the county, is progressing. Several hundred feet of tunnel have been run. In the south tunnel a new vein of ore has been crosscut for 30 feet and no sign of the opposite wall. In the west tunnel a number of small rich veins have been struck, all leading in the direction of the main workings. It is the intention of the company to thoroughly develop this property. In the regular working of the mine they are taking out and milling 300 tons a day.

Lewis and Clarke County.

The crosscut on the vein in the Copper Hill mine of the Red Bird Co. at Austin has been run 25 feet, and there is no opposite wall. The ore is copper and iron and the company has a contract for a car a day as soon as the spur from the railway at Austin is completed. The company has placed steam hoisting machinery at its Reliance group in High Ore gulch, and is taking out a large amount of high-grade smelting ore from development work. New and improved machinery is being placed on the Red Bird, near Austin, and the production will be increased.

The Liverpool, in Lump gulch, continues shipments from development work, shipping six cars in March to the East Helena smelter, which netted several hundred dollars to the ton, principally in silver. Assays of the new vein in the 700 level run from 224 to 1230 ounces of silver per ton from large samples of 125 pounds.

President Winscott of the Gold Bond Co., owning the Good Cheer group in Maupin gulch, and the Tunnel property, 4 miles from Helena, says preparations are being made to start development on the Good Cheer group, 15 miles from Helena. There is a 60-foot shaft, which will be sunk to 200 feet and levels run, and stoping commenced. A tunnel will also be run on the vein, which carries 6 feet of ore at the surface, and this will give a depth of 1000 feet before reaching the shaft. The tunnel will be run 700 feet. The ore runs a smelter average of $30 per ton. A new vein has been discovered in the White Pine properties, owned by Schmidt and associates of Helena. The claims are in Warm Springs gulch, 9 miles from Helena. The new strike is the richest that has been made in these properties.

Ravalli County.

The Wood Placer Co. has taken possession of the diggings at Hughes creek, near Hamilton, which were operated last year by J. A. Nelson of Indianapolis, under contract with the Wood Co. The Wood Co. will resume operations soon, employing fifty men.

Silver Bow County.

The annual report of the Alice G. & S. M. Co. of Butte has been published, in which President M. H. Walker shows that expenditures exceeded receipts during the past year to the amount of $5303.03. The report of Superintendent Buzzo states that considerable attention was given during the past three years to the treatment of the complex zinciferous ores in the Alice and other mines belonging to the company. These ores commence at about 300 feet from the surface and on the 400 level of the Alice mine average 17% zinc, 8% lead, 9% iron, 1% copper, 30.4% silica, 8 ounces silver and $1.60 per ton in gold. Various methods of treatment have been tried, particularly wet concentration and magnetic separation, but the losses attending thereto have thus far interfered with satisfactory results. In addition to the working tests, 200 tons were sent to the mills in Colorado and Utah, where it was treated with care. From all tests made it is manifest that if the ore carried a higher percentage of lead the outcome would have shown a profit. Recent prospecting on the 600 level of the Alice mine shows the average per cent of lead in the vein to be 13½, as against 8%, and zinc 20%, as against 17% on the 400 level. When desirable the 60-stamp mill, which has remained intact since closing down, October 1, 1899, can be used for a concentration plant, and the White-Howell roasters brought into service to aid in extracting the iron from the zinc. Superintendent Buzzo further says that it is evident that at depth the ores of lead-zinc, bearing also copper, silver and gold, will be susceptible to treatment by concentration and magnetic separation, requiring only to be worked upon a generous scale to pay.

Attorneys for the Amalgamated C. Co. have filed in the State Supreme Court an appeal from the order of Judge Clancy, denying a new trial in the Minnie Healy mine case, which had been adjudged the property of F. A. Heinze. It is reported the Amalgamated Co. will ask in connection with the appeal that the Minnie Healy mine be closed pending a decision on the appeal. Unless the case is advanced on the calendar, it will not be argued for a year or more.

NEVADA.

Esmeralda County.

The discovery of coal is reported 30 miles southeast of Sodaville, near the railroad building to Tonopah. The vein is said to be 12 feet thick, at a depth of 150 feet.

Lincoln County.

(Special Correspondence).—Work was commenced April 6th on the new crosscut tunnel of the Empire Con. M. Co.'s property at Empire Camp. It will be 488 feet in length and will crosscut the Empire lead at a depth of 500 feet, or about 700 feet on dip of vein. Drifts will be run east and west 2000 feet each way. The mill will be erected on the millsite adjoining this tunnel.

The Searchlight M. & M. Co. at a depth of 250 feet have encountered a 15-foot body of quartz, averaging from $20 to $25 in gold. They have a good milling ore all the way down.

One of the near and interesting probabilities of this section is a railroad from Ibex, on the Santa Fe, to a connection with the new Salt Lake road, via Searchlight.

Searchlight, April 16.

F. Gardner reports a new find in the Pioche-Nevada Con. mine, near Pioche, in the shaft at depth of 45 feet. The entire bottom of the shaft is in ore.

Nye County.

(Special Correspondence).—The Goldfield M. Co., at Goldfield, represented by J. R. Duffield, is the owner among six others of the January claim, which is one of the important producers in the camp. This claim was leased to Patrick, Kendall, Jones & Reilly on February 5th, and the first shipment made February 16th of 100 sacks of ore. Since that time there has been shipped by the lessees 275 tons of ore which will net $150 per ton. There is also on the dump from 1200 to 1500 tons of mill ore which will average $30. There are two shafts on the property, one an incline to a depth of 112 feet and the other a vertical 100 feet deep about 75 feet west of the inclined shaft. These are connected at the 50-foot level and drifts are being run in the bottom to connect. The vein has been crosscut at the bottom, showing 35 feet of ore, with the foot wall not yet in sight. The Combination claim, adjoining the January on the east, which is also a large producer, has another ledge at 165 feet in depth, showing high values.

Goldfield, April 18.

The ore in the shaft of the Combination, at Goldfield, is changing from oxides to sulphides. The values of the sulphides in the Combination assay $300 per ton.

J. P. Harvey, local representative of P. Clark, started to develop two springs and a few days ago struck a flow of 3 to 5 miner's inches. The shaft on the Combination is down 170 feet and they are drifting both ways on the 130-foot level. Stoping has been started on a 4-foot streak of ore in the 80-foot level. This is the first stoping done in the Combination, the ore heretofore coming from development work.

A gold discovery was made on Gold reef 2½ miles southeast of Gold mountain, says the Tonopah Bonanza. The discoverers are G. Gordon and T. Ahern. They came upon the top of a ledge carrying mineral 2 feet from the surface.

The rock has the appearance of porphyry and carries a black mineral resembling manganese oxide. Samples of the rock have been assayed. The highest return given is $370 in gold, and other assays running from $8 to $40, all in gold. Neither wall of the ledge has been found. The gold belt, according to Mr. Gordon, is 3600 feet wide by 6000 feet long as far as prospected.

It is out on the open desert. Back of it some distance is a range of mountains. By the wagon road it is 9 miles from Tonopah, but on a bee line not over 6 miles. The group is known as the Rattler. The claims are Rattler, Montana, Compromise and Dawn. The owners are G. Gordon, T. Ahern, J. Hall, F. M. Field and R. Wampler. The first strike in that locality was made a month ago in the Conglomerate group by Kielhofer, Graham and Campbell.

They have a ledge of the same rock as the Rattler, but is colored with red and brown iron. Otherwise the characteristics are much the same. The Conglomerate lies about 2000 feet to the northward of Rattler. Hall and Campbell have another group in that district. This ledge is large and of the same character as the others.

Washoe County.

It is reported that W. C. Williams has sold his Cabin and Cabin No. 2 mines in Olinghouse canyon to I. Miller, president of the Springfield M. Co. of Reno. Twenty-five thousand dollars is the consideration stated. The Cabin and Cabin No. 2 have been producers for several years. There is a millsite that goes with the mines, also a water right.

The Forlorn Hope mine in Olinghouse canyon is drifting south to connect the new shaft with the old at the 100-foot level. The new shaft is down 50 feet and shows 16 inches of $20 ore. In the drift a better grade is found. At the Crown Point a drift is being run north on an ore shoot in which values are $10 per ton free milling.

NEW MEXICO.

Sierra County.

The Richmond group, owned by the Gold Mines Co., is near Hillsboro. The company owns a millsite and water right on Percher creek, which gives water sufficient for all uses and an ample water power for operating a 100-ton mill during the entire year. The erection of a 50-ton mill is contemplated. Formerly the ore was shipped to the smelters at El Paso, Texas. All the lower grades were piled on the dump and some left in the stopes. The values of these ores averaged from $4 to $20.

NORTH CAROLINA.

Mecklenburg County.

(Special Correspondence).—The Capps mine, 5½ miles northwest of Charlotte, has passed into the control of the Capps M. Co., who are making preparations to resume operations on a large scale and to add a chlorination plant to their 10-stamp mill and concentrators. This property is one of the oldest and best known mines in the southern district, having a record of about $2,000,000. The property is well equipped with machinery for extensive operations, and has three working shafts —90, 160 and 180 feet deep—and over 2000 feet of underground levels. The company is considering an offer from English ore buyers to take its entire output for export to the English smelters.

Charlotte, April 16.

OHIO.

The Pollock bill, indorsed by the Ohio Mine Workers, was passed by the senate last week. The bill requires the operators of coal mines to employ one man, whose duty it shall be to have full charge of the firing of all blasts. No blast is to be exploded until after the miners have left the shaft or slope at the end of the day's work. It is claimed by the author that this will result in the saving of many lives.

OREGON.

Baker County.

G. Carter, consulting engineer for the I. X. L. and now in charge of the cyanide plant near Baker City, says that the additional battery of stamps has been set up and the boiler is being placed. The extra stamps will be ready to go into commission within a week. This will double the capacity of the plant, making about twenty tons of ore a day.

M. Sullivan, one of the owners of the Lucy group in the Greenhorn mountains, says work at that property is progressing. The Lucy ledge, cut recently, shows 18 feet of ore, with values from $6 to $50. The crosscut will be continued for the O. K. ledge, a distance of 250 feet. This is the main lead of the group. The outcrop, Mr. Sullivan says, has given assays as high as $150, while the Lucy ledge never showed such surface values.

Jackson County.

It is reported that the Millionaire mine has been sold for $40,000. The property is 25 miles from Grants Pass. M. P. Ward will begin work at once and buy the necessary machinery, pumps and hoists.

SOUTH DAKOTA.

(Special Correspondence).—The outlook for mining in the Black Hills the coming summer is good. There is much activity in all of the old districts and considerable in new fields, as well as in some that have been idle for several years. In Rochford district and Hornblende district, near it, the ores are mostly gold. Numerous rich deposits were found at and near the surface in early days of these districts, but, after mining them, operations were in many cases suspended. It is now found that the auriferous pyrite can be concentrated and treated at a profit. Some of the veins are of large size and will justify big mills At Galena, east of Deadwood, the Branch Mint Co. intend to build a cyanide plant this spring, and the Ruby Co., in this district, also contemplate building a 100-ton plant. At Lead City 100 stamps are being added to the Amicus mill, and it is reported that sixty more will be added, which will make a total in this mill of 300 stamps, with a capacity of 1200 tons daily. The Deadwood-Standard Co. is to increase their cyanide plant by addition of more tanks. At the Clover Leaf, near Perry, the shaft is to be sunk to 1000 feet, and it is reported that the

lower workings show an improvement in the vein, which is there more regular. South from Perry a good deal of prospecting is going on, particularly on upper Box Elder. In this district the formation is identical with that at Lead City, excepting that there are no intrusive porphyry dikes. West of this section and about the head of Silver creek are promising copper prospects in black slate and quartzite. On upper Box Elder is found conglomerate containing copper. About Custer there is a great deal of prospecting for gold. In this district the formation is mostly mica schist with granite dikes, and some very rich ore has been found; but the rich spots do not hold out and the low-grade ores seem by comparison worthless; but some of the veins are large and carry enough gold to make the property profitable, if properly equipped and managed. Timber and water are plentiful almost everywhere. The coming summer promises to be a prosperous one for the Hills.

Rochford, April 16.

Lawrence County.

The Lucky Strike mine, 2½ miles south of the Uncle Sam mine and owned by the Clover Leaf Co. at Perry, is sinking the shaft with a horse whim. When the shaft gets somewhat deeper a steam hoist will be put in.

A new mill is projected by the Gilt Edge-Maid M. Co. in Strawberry gulch, Bear Butte mining district, near Galena. It is to be a cyanide plant for the treatment of ore from the Gilt Edge and Dakota Maid properties. G. A. Duncan and O. P. Ankeny of Deadwood and others are at work on the enterprise.

The Puritan M. Co. has recently bought the 10-stamp mill of the North Star M. Co. and will move it from the North Star mine, near Custer, to the Puritan in Strawberry gulch. The company has also bought the North Star hoist and will move it at the same time.

Another shoot of ore has been found at the Penobscot mine, at Garden City, east of the main shaft. It is one of the strongest yet found in the mine. Of late this company has been prospecting beyond the line of actual mining and preparing the way for future years. A new compressor has been ordered, capable of driving twenty-four drills.

Pennington County.

The Lucile G. M. Co. was organized recently to develop and operate a group of mines near the head of Irish gulch, 1 mile north of Rochford, and near the Montezuma mines.

TEXAS.

Matagordo County.

An oil gusher was struck last week in the Big Hill oil field, at a depth of 870 feet. This is the first gusher in that field. The oil spouted 50 feet above the derrick.

UTAH.

Box Elder County.

The Utah C. Co. of Bingham is forwarding big consignments of concentrates to the smelter.

The Utah C. Co., owning the large concentrating plant at Bingham, contemplates the installation of concentrating tables, says Manager Jackling. The mill has a capacity of 1000 tons per day.

Juab County.

It is reported at Eureka that the Sioux and Utah mines are to be included in the proposed amalgamation of the La Reine and Beck Tunnel, the Cyrus Oliver and Salvator. R. D. Grant, owner of the Sioux and Utah mines, says while such a consolidation of interests would be of advantage, the Salvator, owned and operated by J. Knight, is developing a body of argentiferous-gold ore, showing fifty-four ounces silver, with $14 gold, the lessees of the Sioux have ore containing silver, lead and gold.

Manager Joseph of the Carisa, Tintic district, says now that the road between the mines and the leading station has improved shipments will increase. At the mine arrangements are being made to sink the shaft to 900 feet. Lessees are taking out ore, while the company is raising the usual tonnage.

The directors of the Tesora of Tintic district have arranged to have the mill moved to Bingham for the Bingham Con. M. Co., where it will be used in connection with the Dalton & Lark mines to concentrate the second-class silver-lead ore.

Salt Lake County.

In Alta district the winter is broken and claim owners have comenced work. The superintendent of the Alta-Quincy reports a strike at that property where the tunnel has cut 8 feet of copper ore.

A strike is reported made at the Continental-Alta mine at Alta, in the winze sunk from the lower Grizzly tunnel. Manager H. M. Crowther says the ore is of milling grade and will concentrate about 8 to 1. The ore carries gold, silver and copper. The vein is 10 feet in width and is on the contact between lime and porphyry.

The South Columbus will cut the Alta-Quincy, which it adjoins on the east. The tunnel will open an ore body at a vertical depth of 1000 feet, which was worked on the surface.

Summit County.

The Ontario's new concentrator at Park City is handling an average of 100 tons of ore per day.

A new station pump has been ordered by the New York Bonanza Co. Manager Wilson says it has a capacity of 300 gallons of water per minute.

Ore shipments from Park City for week ending April 15 were as follows:

	Pounds.
Ontario	816,000
Daly-West	2,523,000
Kearns-Keith	31,000
	3,400,000
Total	5,108,060

Tooele County.

The Black Diamond M. Co., at Stockton, is preparing to sink an incline to connect with the Honorine tunnel, for the purpose of transportation and ventilation.

WASHINGTON.

Ferry County.

C. M. Fassett of Spokane is at the Bedie mine, west of Republic, accompanied by F. H. Flood, who will install and manage the cyanide plant at the new mill. The frame for the plant is up and the mill should be running by July 1.

King County.

The discovery of gold in the suburbs of Seattle is reported. The gold is said to occur in black and ruby sand, and is apparently an old beach, on which layers of heavy sand and gold have been concentrated by the waves.

Stevens County.

W. E. Harris, manager of the Review M. Co., reports a strike in the 140-foot crosscut tunnel. The ore shows galena mixed with gray copper, iron and zinc. This property consists of five claims and lies on the west side of the Columbia river, 2½ miles from Northport. It is an old property, first located in 1892, before the reservation was opened, and again in 1896 by the present owners, after the reservation was opened. The latter location brought on a legal battle that ended in the United States Supreme Court in favor of the present owners, G. Reith of Holly, Mason, Marks & Co., H. Baer of Spokane and W. E. Harris of Northport. The title is now clear. The place where the ledge was tapped is 130 feet in depth. The surface showing is quartz 100 feet in width and has been prospected for nearly 1200 feet.

FOREIGN.

AFRICA.

Transvaal.

The mining department of the Transvaal has published its report showing the trade returns of the colony for the fiscal year ending June 30, 1903. The imports relating to the mining industry exclusively are valued at $22,739,187 as against $8,966,840 in the fiscal year preceding. Of this amount 93.03% represented the value of stores consumed in the gold mines, 5.45% the value of stores consumed in the coal mines, 0.51% that intended for the diamond mines, and the remaining 1.01% for the chemical and metallurgical plants. The value of stores consumed in the gold mines averaged $7.668 per effective stamp. In 1898-99, the year before the Boer war, these imports averaged $5.03 per stamp.

AUSTRALIA.

Queensland.

The gold returns of Queensland for the month of March are reported by the London Mining Journal as follows:

	Tons Crushed.	Yield, Ounces.
Charters Towers	23,100	24,600
Croydon	3,700	2,300
Gympie	20,200	12,900
Mount Morgan	20,900	8,900
Ravenswood	2,200	2,500
Other Fields	5,800	3,600
Alluvial		900
Total yield		55,700

The yield for the March quarter was 145,000 ounces. The following calls were made and dividends paid in March:

	Calls.	Dividends.
Charters Towers	£8,600	£30,100
Croydon	500	3,000
Gympie	6,400	43,500
Mount Morgan	Nil	12,500
Ravenswood	1,300	Nil

BRITISH COLUMBIA.

Boundary District.

Ore shipments from the mines of the Boundary district for the week ending April 16 ran over 15,480 tons.

Rossland District.

As a result of a conference between Superintendent R. C. Morgan of the S. F. & N. R. R., Manager Wilson of the Northport S. & R. Co., and Acting Manager J. H. MacKenzie of the Le Roi, held at Rossland, the ore train and local switching crews have been put to work. The Le Roi is again hoisting ore and will resume shipments to the Northport smelter.

At the Le Roi mine, Rossland, fifty men have been added in the last few days, says the Miner. Others will be put to work from day to day. Seventeen machines are at work in the mine. It is expected that within a short time the full crew of 425 men will be restored to the Le Roi.

The Le Roi No. 2's concentrator at Rossland is running steadily, though the oil feature is not operated.

MEXICO.

Chihuahua.

S. G. Burn of Tom's River, New Jersey, is in the city of Chihuahua to commence work on the Josefina mine in Santa Eulalia for the company recently organized by J. H. Furman to exploit the property. Mr. Burn is accompanied by C. J. Burnup of London, England. The company is composed of English and New York people.

There are fourteen diamond drills in the Santa Eulalia camp, all of which are in operation on nine different properties. It is diamond drills that have brought the Santa Eulalia district into prominence within the last two years, says the Chihuahua Enterprise. Their use has done more to locate and develop the ore deposits in the lime mountain than anything else. The camp has a record of $600,000,000 in production and stands a good show to repeat itself, and the diamond drill will henceforth be a leading factor. There is a large area of Santa Eulalia that has not been scratched.

The Terrenates Con. M. Co., operating in Parral, has been reorganized as the United States M. Co., with J. P. Elkin of Pennsylvania as president and J. W. Marshall as manager. The 600 H. P. electric plant is installed and said to be working well. The power is used for lighting and hoisting and later will be applied to the pumps. The station pumps are at the mine and the others are to arrive.

NEW ZEALAND.

At Waikine the management has been experimenting with the new grinding plant, and, so far as experiments have progressed (with sands only), the results obtained have exceeded expectations, says the London Mining Journal. The working of this mill is about to make a radical change in dealing with the residues from the whole of the company's mills. This mill will serve the great purpose of effecting a further percentage of bullion extraction, not only from the sands, but the importance of being able to deal with their own concentrates right from the stamps. It is reported that the working costs have been reduced and that fully 2s 6d per ton has been saved during the past year. Taking the quantity of ore treated during 1903, namely, 231,000 tons, the actual saving effected is £24,000.

RUSSIA.

St. Petersburg advices say that since the commencement of the war in East Asia the Amur gold miners have stopped work, all Chinese laborers giving up their places. Many orders for gold dredgers given by the Siberian miners have been cancelled. It is said that several miners have got into difficulties and that the Government intends to make arrangements which would enable the miners to enlarge the production. In the iron districts the mines are working hard to fill the demand arising through the war. At the River Jenissei, not far from Krasnojarsk, large coal mines have been bought by the Government. Twelve to fourteen million puds are wanted every year by the Krasnojarsk district railway.

SOUTH AMERICA.

Argentine.

F. D. Harford of Buenos Ayres reports great development taking place in gold mining in the north of the Argentine Republic, especially on the Bolivian frontier, says the London Mining Journal. The gold dredging system is likely to be tried to some extent, under the advice of practical New Zealand and Australian mining engineers. The Argentine mining code, however, is said to compare unfavorably with the Bolivian mining code. Very high fees, too, have to be paid in Argentina for mining licenses to prospect and work new districts.

Dutch West Indies

The Aruba Gold Concession report, March 28, the return of 202 ounces of gold from 432 tons of ore treated.

Personal.

J. M. Lynch, a mining man of Ely, Nev., is in Salt Lake City, Utah.

Thos. J. Barbour left London on the 20th on his return to San Francisco, Cal.

T. Jacobson, president of the Columbus Con. M. Co. of Utah, is in Chicago, Ill.

W. L. Cobb of San Francisco, Cal., is putting up a 20-ton cyanide plant at Piute, Cal.

H. S. Shaw, a mining operator of Denver, Colo., is in the Black Hills of South Dakota.

J. W. Van Meter left San Francisco, Cal., this week on a ninety-day visit to London.

P. Porter of Salt Lake City, Utah, has gone to Chicago, Ill., on mining business.

A. N. Caton of Chicago, Ill., is examining mining property at Charleston, in northern Nevada.

E. H. Barton, superintendent of the Yellow Aster mine at Randsburg, Cal., is in San Francisco, Cal.

A. C. Lawrence, a mining man of Negales, Ariz., has gone to Sonora, Mexico, on mining business.

W. R. Thomas, superintendent of the Central Eureka mine at Sutter Creek, Cal., is in San Francisco, Cal.

Sydney Reeves, head assayer for the Fremont Con. M. Co. near Amador City, Cal., is in San Francisco, Cal.

R. Guensher has succeeded A. E. Snow as manager of the Martha Washington mine at Robinson, Utah.

D. L. Gregg, local manager of the Mine & Smelter Co. at El Paso, Texas, has returned there from Denver, Colo.

G. A. Laird has resigned the managership of the Victoria mines, Cerro de San Pedro, San Luis Potosi, Mexico.

E. H. Stagg, manager of the Chase Con. mines at Rochester, Cal., has returned there from Randsburg, Cal.

J. D. Wood, vice-president of the Daly-West M. Co. at Park City, Utah, has returned there from Los Angeles, Cal.

C. M. Fueller, Denver, Colo., has returned there from Georgetown, Colo., where he was examining mining properties.

J. Hoatson, superintendent of the Lake Superior & Pittsburg Co. at Bisbee, Ariz., has gone to Chicago, Ill., on company business.

P. T. Farnsworth, manager of the Bullion-Beck mine, in Tintic district, Utah, has returned to the mine from Salt Lake City, Utah.

D. R. Jackson, general manager of the Santa Eulalia Exploration Co. of Chihuahua, Mexico, has returned to the mines from the United States.

W. H. McCord of Guanajuate, Mexico, superintendent of the Peregrina mine, near that city, has returned there from San Francisco, Cal.

John M. Beckwith, E. M., now making a geological survey of a portion of Egypt, expects to return to London, England, during the summer.

F. Ames of Deadwood, S. D., has resigned from the superintendency of the Wauconda M. Co. to take a similar position with the Custer Peak Co.

William Russell, who lately returned to Denver, Colo., from southern California and Arizona, has gone to Sheridan, Mont., where he will be all summer.

L. D. Sivyer, who has been engaged for the past several months in mine examination and geological work at Globe, Ariz., has returned to Los Angeles, Cal.

Harris Franklin, manager of the Golden Reward M. Co. of Deadwood, S. D., has returned from an extended trip through the West and South, including Cuba.

The American Steam Pump Co., Battle Creek, Mich., in Sec. 2 of their catalogue No. 11 give condensed data concerning their Marsh tank and vacuum pumps.

As a member of the Panama Canal Commission the salary of C. E. Grunsky is $12,500 per annum, with $15 per day additional for all time spent on the Isthmus.

John Chalmers, chemist and mill man at the Wano mill, Jamestown, Colo., has

resigned his position, to take effect May 1, and will be at 1750 California St., Denver, for a time.

THE American Con. C. Co., Lordsburg, New Mexico, has elected G. H. Patterson of Colorado director and manager of its properties in New Mexico, succeeding A. R. Gibson, resigned.

JOHN LAWLER, owner of the Hillside mine, 30 miles north of Hillside station, Yavapai county, Arizona, has returned to Prescott from the mine, where development work is in progress.

H. S. MUNROE of Columbia School of Mines, New York City, has returned to New York from the Cripple Creek district, Colo., where he has been endeavoring to make arrangements for a summer school among the mines of the district.

Commercial Paragraphs.

W. M. WALLACE is the manager of the new San Francisco, Cal., office of the National Supply Co.

THE offices of the Wetherill Separating Co. have been removed from 68 Broad street to 52 Broadway, New York City.

THE Lunkenheimer Co., Cincinnati, O., send a fine enameled hanger of unusually handsome design and execution as a wall ornament, advertising their steam specialties.

THE Hydro-Carbon Manufacturing Co. of Denver, Colo., has closed a contract with the Denver Union Water Co. to supply them with their dipping and brush paints. They will double tbe capacity of their present paint factory.

THE first-class armored cruiser California, under construction for the United States Government at the Union Iron Works at San Francisco, Cal., will be launched on the 28th inst. under the auspices of the Native Sons of the Golden West.

THE Crocker-Wheeler Co. will carry in their Denver, Colo., branch a complete stock of motors and dynamos ranging from ½ to 50 H. P. motors and 1½ K.W. to 11½ K.W. dynamos, and will issue a stock list monthly, which will be mailed on application.

THE Brown-Corliss Engine Co. of Corliss, Wis., have an order from tbe Phillips Insulated Wire Co. of Pawtucket, R. I., for one 14 and 28x42-inch tandem compound condensing Corliss engine, and one 18 and 36x48-inch tandem compound condensing Corliss engine.

ARTHUR WARREN is manager department of publicity of the Allis-Chalmers Co., with offices at Milwaukee, Wis. Communications regarding publicity in connection with this company, including the Bullock Electric Co., recently absorbed, should be so addressed.

A NUMBER of officials of representative manufacturing concerns in Cleveland, O., have recently organized "The Manufacturers' Advertising Club." The officials of tbe club are: Charles B. Schenks of the Winton Motor Vehicle Co., president; William Townsley Jr. of the Grasselli Chemical Co., vice-president; Miss E. L. Harmon of the Low Supply Manufacturing Co., treasurer; Mrs. F. A. McIntosh of the Standard Tool Co., secretary. Considerable interest has already been created by this organization.

Trade Treatises.

Synopsis of the S. K. C. system, elaborately illustrated. Stanley Electric Manufacturing Co., Pittsfield, Mass.

Circular 73 from the Jeffrey Manufacturing Co., Columbus, Ohio, gives a general summary of all the Jeffrey machinery.

THE biggest catalogue of the year so far received—750 pages 9x12—comes from the Niles-Bement-Pond Co., N. Y., finely systematized.

Catalogue No. 4 from the Marvin Electric Drill Co., Binghamton, N. Y., makes a good showing for the Marvin drill and electric power in connection therewith.

Table of charges for assays, analyses, mill, treatment and smelting tests; compact and complete. The C. A. Luckhardt Co., 71-73 Stevenson street, San Francisco, Cal.

A pamphlet on "Long Distance Transportation of Ores by Aerial Wire Rope Tramways," issued by A. Leschen & Sons Rope Co., 920-922 North First street, St. Louis, Mo., is of present value to all interested in that form of telpherage.

Latest Market Reports.

SAN FRANCISCO, April 22, 1904.

METALS.

SILVER.—Per oz., Troy: London, 24 1/16d (standard ounce, 925 fine); New York, bar silver, 53⅜c, refined (1000 fine); San Francisco, 53⅜c; Mexican dollars, 43½ San Francisco, 43c New York.

COPPER. — New York: Standard, $13.25; Lake, 1 to 3 casks, $13.25; Electrolytic, 1 to 3 casks, $13.12½; Casting, 1 to 3 casks, $12.87½; San Francisco: $15.00. Mill copper plates, $17.00; bars, 18@24c. London: £57 18s 9d spot per ton.

Following are the figures of German consumption of foreign copper for the months of January and February, 1904, compared with the same period of 1902-1903:

	1904. Tons.	1903. Tons.	1902. Tons.
Imports	19,778	12,504	9,705
Exports	1,215	1,725	1,483
Consumption	18,563	10,779	8,222

LEAD. — New York, $4.65; Salt Lake City, $3.50; St. Louis, $4.25 San Francisco, $4.50, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½, sheet 7, bar 5¾c; pig, $4.85. London: £12 2s 6d ₱ long ton.

SPELTER.—New York, $5.25; St. Louis, $5.00; London, £22 5s ₱ ton; San Francisco, ton lots, 6¾c; 100-lb. lots, 7c.

TIN.—New York, pig, $27.87½@28.12½; San Francisco, ton lots, 29½c; 500 lbs., 30c; 200 lbs., 30½c; less, 31c; bar tin, ₱ lb., 32½@35c. London, £127 2s 6d spot.

PLATINUM. — San Francisco, crude, $18.00 ₱ oz.; New York, ingot, $19.00 ₱ Troy oz. Platinum ware, 75 @ 82c ₱ gram.

QUICKSILVER. — New York, $45.50@46.50, large lots; London, £8 5s 0d; San Francisco, local, $43@44 ₱ flask of 76½ lbs.; Denver, $46.00. Export, $43.00@43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER. — Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ₱ lb., 50c; dust, ₱ lb., 10c; sulphate, ₱ lb., .04c.

NICKEL.—New York, 50@60c ₱ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30@34c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.20 @14.35; gray forge, $13.00; San Francisco, bar, 3c ₱ lb., 3½c in small quantities.

STEEL. — Bessemer billets, Pittsburg, $23.00@23.00; open hearth billets, $23.00 @23.00; San Francisco, bar, 7c to 12c ₱ lb.

No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CAPS.—3x, $5.50 per 1000; 4x, $6.50; 5x, $8; Lion, $9, in lots not less than 1000.

FUSE. —Triple tape, $3.60 per 1000 feet; double tape, $3.00; single tape, $2.65; Hemp, $2.10; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11½c ₱ set; 14 oz., 40s., 10c.

CHEMICALS. — Cyanide of potassium, 98%-99%, jobbing, 23@24c ₱ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ₱ 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c ₱ lb.; Cal. s. soda, bbls., $1.20@1.40 ₱ 100 lbs.; sks., $1.05; chlorate of potash, 12@13c; nitrate of potash, bbls., 10c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2@3c; flour sulphur, French, 3¼@3½c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ₱ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ₱ lb.; nitric acid, carboys, 8c ₱ lb.

BONE ASH.—Extra No. 1, 5@6c ₱ lb. No. 1, 4@5c.

COAL. — San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.00; Southfield, $8.00. Cargo lots, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $11.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $11.50, long ton.

OILS.—Linseed, boiled, bbl., 49c; cs., 54c; raw, bbl., 47c; cs., 52c; Lucol oil boiled, bbl., 44c; cs., 49c; raw, bbl., 42c; cs., 47c. Kerosene—Pearl, per gal., 20½c; Astral, 20½c; Star, 20½c; Extra Star, 24½c; Eocene, 23½c; Elaine, 26½c; Water White, in bulk, 14c; Mineral Seal, iron bbls., 19c; wooden bbls., 21½c; cs., 25c; Mineral Sperm, cs., 26½c.; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E W. S., bbl., 85c; cs., 90c; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 60@65c; Natural White, 70c; Bleached, do., 80c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c ₱ lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case, ½c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

RED LEAD.—500 lbs. and over at one purchase, ₱ lb., 7c; less than 500 lbs., 7½c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ₱ lb.

BORAX.—Concentrated, 6@7c ₱ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

MANGANESE.—Pure, ₱ lb., 60c.

SODIUM.—Metal, ₱ lb., $1.00.

BISMUTH.—Subnitrate, ₱ lb., $2.00.

MERCURY.—Bichloride, ₱ lb., 77c.

MOLYBDENUM.—$2.00 ₱ lb.

CHROMIUM.—90% and over, ₱ lb., $1.00.

PHOSPHORUS.—American, ₱ lb., 75c.

SILVER.—Cbloride, ₱ oz., 90c@$1.00; nitrate, 55c.

ALUMINUM.—No. 1., 99%, small lots, 37c ₱ lb.; 100 lbs., 35c; 1000 lbs, 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

URANIUM.—Oxide, ₱ lb., $3.50.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SPRING DOWEL FORMING MACHINE.—No. 756,532. April 5, 1904. J. H. Ross, San Francisco, Cal. Assigned to American Steel & Wire Co. of San Francisco, Cal., a corporation. This invention relates to improvements in machines for forming dowels on coil furniture springs. The object of the invention is to provide a machine for making the dowels rapidly and of uniform length without danger of breaking the spring.

DRAPER.—No. 756,548. April 5, 1904. J. C. White, Marysville, Cal. This invention relates to improvements in drapers for grain elevators, headers, harvesters and the like; and its object is to provide a simple, economical and novel form of lateral reinforcement whereby the draper cloth or canvas may be protected against wear due from constant contact with the guides in which the edges of the draper run.

DRAFT EQUALIZER.—No. 757,232. April 12, 1904. P. V. Schandoney, Sacramento, Cal. This invention relates to an improved means for equalizing the draft of large teams used in hauling combined harvesters, gang plows, or other heavy machinery. The object of the invention is to devise means for connecting up the several elements of the equalizer so that each animal may be made to pull his own load and no more, to provide means for shortening the length of the team for rendering the guiding of these large teams easier, to simplify the connections between successive series of animals, and to maintain all the trees in substantially horizontal position, and thus balance the draft.

DRAFT EQUALIZER.—No. 757,233. April 12, 1904. P. V. Schnndoney, Sacramento, Cal. This invention relates to an improved system of draft equalization employing pulleys and interconnecting draft chains. Its object is to render the pulley type of draft equalizer practical, so that the natural inequalities in the length of the sections of chain passing around a pulley or drum will not react upon the animals on the shorter section to make them haul an undue proportion of the load.

SUPERHEATER FOR OIL BURNER.—No. 757,182. April 12, 1904. J. M. Donahue, Santa Rosa, Cal. This invention relates to a superheating attachment and connection for oil burners in conjunction with furnaces wherein such material is used as a fuel. This consists essentially in a return curved pipe located in the boiler furnace, connection between the steam drum of the boiler and one end of said pipe whereby steam may be caused to pass through the pipe, an oil-conduoting pipe fitted centrally within the steam pipe and following its course and extending back to the front of the boiler, connection between the oil pipe and the burner, and a connection between the steam pipe and the burner.

PICKS AND POINTS.—No. 757,206. April 12, 1904. L. Kovacs and M. Kovacs, San Francisco, Cal. This invention relates to improvements in picks and in the movable points therefor. For the purpose of renewing and repairing the wear of the points of picks which are subjected to the principal wear it is desirable to remove these points, and this invention is designed to provide a convenient and easy method for such removal and replacement.

ARTICHOKE TRIMMER.—No. 757,229. April 12, 1904. A. Roumiguiere, San Francisco, Cal. One-half assigned to R. Hickmott, of same place. This invention relates to an apparatus which is designed for preparing the vegetable known as "artichokes" for canning or for other purposes. The object of the invention is to first remove these leaves, then extract that portion of the interior which is not desirable, leaving the edible base portion in proper condition for canning.

ADJUSTABLE CANOPIES.—No. 757,175. April 12, 1904. E. G. Burland, Watsonville, Cal. The object of this invention has heen to design a canopy particularly for use in undertaking establishments which will answer for all occasions wherever it is desired to display a casket during such time as the remains of one deceased, whether infant or adult, is exposed to view. This canopy is adjustable to a frame of any size and it can be quickly removed from or placed upon the frame.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING APRIL 12, 1904.

756,927.—PEDESTAL—C. H. Ashley, S. F.
757,251.—MUSICAL INSTRUMENT — J. E. Berglund, S. F.
757,173.—DREDGE—A. Boschke, S. F.
757,086.—STATION INDICATOR — R. Bosshard, Los Angeles, Cal.
757,262.—PICTURE HANGER — J. Bryden. Colfax, Wash.
757,175.—CANOPY — E. G. Burland, Watsonville, Cal.
757,176.—SLUICE BOX—C. M. Carter, Sultan, Wash.
756,940—SHOELACE FASTENER—C. A. Conger, Oakland, Cal.
758,182.—OIL BURNER—J. M. Donahue, Santa Rosa, Cal.
756,948.—BOILER FEED—H. W. Fellows, Los Angeles, Cal.
756,949.—SPIRIT LEVEL—R. B. Ferguson, Los Angeles, Cal.
756,951.—HANDLING MATERIAL—R. B. Friend, Oakland, Cal.
756,957.—ELECTRIC RAILWAY—Hanna & Gilman, Rivera, Cal.
757,304.—CHECK HOOK—Hellruth & Taber, Sacramento, Cal.
757,192.—WIRE TIP—S. C. Houghton, S. F.
757,206.—PICK AND POINT—L. & M. Kovacs, S. F.
757,045.—PLANT PROTECTOR — Annie M. Lane, Lakeside, Cal.
757,209.—SASH FASTENER—J. A. Long, Spokane, Wash.
756,871.—SPECTACLES — S. G. Marshutz, Los Angeles, Cal.
757,407.—FISH TANK—L. Mayhall, Sultan, Wash.
756,873.—STAMP MILL—W. A. Merrals, S. F.
757,408.—MUSIC STAND—R. D. Noble, Sausalito, Cal.
757,220.—SMELTING ORES—A. R. Partridge, S. F.
757,221.—SMELTING FURNACE — A. R. Partridge, S. F.
757,222.—SMELTING FURNACE — A. R. Partridge, S. F.
757,229.—ARTICHOKE TRIMMER—A. Roumiquiere, S. F.
757,232.—DRAFT EQUALIZER — P. V. Schandoney, Sacramento, Cal.
757,233.—DRAFT EQUALIZER — P. V. Schandoney, Sacramento, Cal.
757,240.—SKATE—T. Spacie, Globe, Ariz.
757,360.—POTATO SLICER—L. L. Stevens, Los Angeles, Cal.
757,241.—HAIR CURLER — N. B. Stone, Outlook, Wash.
757,154.—BICYCLE—R. H. Tate, Portland, Or.
756,910.—ELEVATING MACHINE—A. P. Tatterson, Stockton, Cal.
756,992.—VEHICLE—C. R. Twitchell, Dayton, Cal.
756,994.—LAMP CHIMNEY—Rose L. Valleen, Seattle, Wash.
757,008.—CONCENTRATOR—G. E. Woodbury, S. F.

MINING AND SCIENTIFIC PRESS

Whole No. 2284.—VOLUME LXXXVIII. Number 18. SAN FRANCISCO, CAL., SATURDAY, APRIL 30, 1904. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

Foresight in Mill Construction.

The cost of mining is influenced to a great extent by the foresight of the management in providing proper means of economically developing and extracting the ore and getting it to the mill or smelter at the lowest expense of labor and materials. But mining is only half the battle. The mill or the smelter, if not in proper hands, may wreck a company as completely as inexperienced management in the mine. After over fifty years of actual practical experience, it would seem that mistakes in the construction of a quartz mill would not be made, or, if appearing, be of little moment; but such is not always the case, for mills are still being constructed along lines far removed from the acknowledged best practice.

The first thing for mature consideration when contemplating the building of a mill is the selection of a proper site. If the ground be flat, there is little choice, except to secure as substantial a foundation as possible; but in a hilly country there are often several sites from which to choose. The mill should be located in such a manner, if possible, that the ore may be delivered at the end of the mill, and not at the middle of the rear portion, as is often seen. The site selected should include a suitable situation for a sulphur house, and, where necessary, also a canvas plant and cyanide works. All should be arranged with a view to automatic passage of pulp from each stage of the operation to the next by gravity. Where this is precluded by reason of being on a flat, conveyors of various types afford an economical means of carrying ore or pulp from one portion of the works to another.

The next thing to be considered is foundations. This is most important, for, to a great extent, upon proper foundations depends the life of the building. If bedrock is near the surface—5 to 20 feet—an excavation should be made to bedrock and terraces cut into the solid rock to afford a substantial and enduring base for the superstructure.

Where the bedrock shows a tendency to cave, retaining walls must be built of rock or concrete. If water under pressure is available the superficial debris and loose rocks can be removed more quickly and cheaply by hydraulicking than in any other way. Sills must not be laid upon the ground, for the changing seasons, the alterations of moist and dry atmosphere will cause sills so placed to rot quickly. In the past a great deal has been published in the MINING AND SCIENTIFIC PRESS on mortar block construction, but there seems to be no uniformity of opinion on this matter. Wooden mortar blocks properly built have been known to last for years, and in some instances they have proven short-lived. Concrete blocks have their firm adherents, and there are those who say they are not satisfactory. That concrete mortar blocks must be built of the best and strongest material goes without saying—a cheap concrete block will not withstand the vibration of the heavy fall of the stamps.

How Stamps of Homogeneous Steel Wear in a Properly Fed Battery.

Amalgam Grinder in the Cleanup Room.

All mills should be supplied with suitable devices for quickly and cheaply moving heavy fittings from place to place. For this purpose there should be a track and traveler above the plate floor, with chain blocks, in order that shoes, dies, etc., may be moved where they may be required without delay, and with the least amount of labor. Similarly above the cam floor should be arranged a track and traveler, with chain blocks attached, for the purpose of distributing cams, raising stamps, removing stems, etc., and this track should be extended outside the mill, to facilitate the bringing into the building of these and similar things. In large, well appointed, modern mills these conveniences are provided, and it lessens and cheapens labor. By means of chain blocks, track and traveler, two men can do what would otherwise require half a dozen or more. Many mill men know what it means to "lug" a stem up a narrow stairway, and to haul it up to the cam floor with a common "snatch" block is only a makeshift. A good plan is to have an extra cam shaft, with cams all set, on the cam floor and in readiness to be taken to any battery where it may be needed. The shaft requiring repairs may be removed, the extra substituted in its stead, and in less than an hour the ten stamps are again dropping, while the other is being put in good condition for a similar service, should the necessity arise. For the handling of a cam shaft it is advisable to have a separate track on the side of the battery adjacent to the cam shaft so that it may be lifted out and placed on a trolley and sent to one end of the mill, where it may be let down to the ground to be sent to the machine shop. The accompanying illustrations are familiar scenes about a gold mill.

A Familiar Scene at the Back Door of the Mill.

The upper picture shows how stamp shoes which are made of homogeneous steel will wear when the feeding is properly attended to. Often shoes will wear until less than ½ inch of metal remains on the shank. The pile of dies in the lower left-hand corner furnishes another illustration of economical use of dies. The consumption of iron or steel in stamp mill shoes and dies per ton of ore crushed is dependent upon the character of the ore and the height of discharge, and also to some extent on the amount of water used, and very largely on the feeding. If a battery is overfed, crushing will be slow and the consumption of iron or steel will be relatively low. Iron shoes and dies do not wear as well as steel, but are considered economical.

The American Mining Engineer at Home and Abroad.

In a recent issue of the Iron Age, J. H. Curle, a mining engineer of London, has this to say of American mining engineers:

The American has played a great part in the development of the Transvaal mines, and to-day holds most of the big positions. He has left his mark as a brilliant judge of machinery or as an engineer gifted with financial genius, rather than as a mine manager. He is imaginative, and takes at the same time a broad grasp of the position; but, in the detail work of management, where a concentration of character is necessary, he has not shown to equal advantage. Far be it from me to decry that wonderful product of the age, the California-reared mine manager; but I class equally with him many Britishers. As mine managers we can show fine men, on the Rand or elsewhere; but we lack that mining instinct, that knowledge of values, and that grasp of the whole mining horizon which so many of the American engineers possess. America is a metal mining country, and England is not. We have not in England the mining atmosphere which is ever present in the States; and it is because of this, not from any inherent defects of mind or character, that we are handicapped in the race.

This is a deserved tribute to the ability and ingenuity of the American mining engineer, but it occasions some surprise that he is not credited with being a good manager of general mining operations, but is considered as more distinguished as a successful "financial genius," or a "brilliant judge of machinery." Knowing and judging the American engineer by his work at home, where he has demonstrated his ability to manage mining affairs in a manner that has never been equaled elsewhere in the world under similar conditions and circumstances, it is presumable that the average engineer of experience would do as well on the Rand as elsewhere. The engineer or manager who can operate a gold mine, where the ore carries only 25 or possibly 50 cents per ton profit under the exercise of the strictest economy permissible with the proper operation of the mine, and successfully keeps within that limit, year after year, enlarging the plant and the scope and magnitude of operations, while constantly larger dividends are being paid on an ore of increasingly lower grade, can manage a mine in the Transvaal or anywhere else, and there are many such men in the United States, of whom it is no exaggeration to say they have done and are still doing just such things as are above referred to. The writer of the above article may have had some particular individual or individuals in mind at the time, for his remarks do not apply with force to the majority of Western mine managers who have "grown up with the business" and made it what it is.

Rich mines are prone to make extravagant managers. The early days of the Comstock showed this to be the case, but in more recent years the propositions which mine managers have had to handle have been of a different sort. Large, low-grade mines — and not always large either — where every cent of cost per ton had to be considered, are the sort the American engineer has had to handle. If one seeks a careful, capable, conservative mine manager, he will find him in the man who has made success under the adverse conditions here described.

Cost of Mine Drainage.

One of the most serious problems that confronts many mine managers is the expeditious and economical handling of water, which sometimes occurs in large volume at unexpected and always unpropitious times, though in some mines the flow of incoming water is both large and constant. At some of the greatest mines of the West this problem has been reudered easy of solution, though the means employed involved great expense—that of drainage by tunneling. Undoubtedly the drainage of mine workings through tunnels driven for this purpose, and incidentally also serving as a means of ventilation and transportation, is the most satisfactory way to solve the perplexing problem, where the topography of the country admits of the possibility of attaining a depth sufficient to justify the expense. Notable examples of drainage by tunnel are found in the Sutro tunnel, which drains the Comstock mines at Virginia City, Nev., to depth of 1750 feet; the Ontario tunnels at Park City, Utah, which relieved that mine of a tremendous and ever present volume of water to great depth; the Yak tunnel at Leadville, Colorado, draining mines on Breece hill, to a depth of more than 1000 feet; the Kellogg tunnel, at Wardner, Idaho, draining the Bunker Hill-Sullivan group to a depth of over 1000 feet; and more recently the El Paso tunnel, draining important mines in the Cripple Creek district of Colorado. All these tunnels were driven at great expense, though no one will deny that in each of the instances mentioned the results justified the expense, and have proven to be and will continue to be an economical investment, but in time mines so drained reach a depth below the drain tunnel level, and then, if the lowest practicable level has been drained by adits, some other means of handling the water must be provided. Most mines are so situated that tunnel drainage is limited to comparatively shallow depth, and in such as these the water problem is usually ever present and must be met in the most economical manner possible.

In those cases where a mine cannot be drained by means of a tunnel, the management has usually the choice of raising water by means of pumps or by hoisting with skips or buckets.

When the shaft is being sunk it is impossible to ascertain or to even estimate the amount of water that may be encountered. In some mines the quantity varies greatly with the season, and also varies from no apparent cause. In such cases as the latter, and, in fact, in every case, it is necessary to have ample provision to take care of the maximum amount. The usual method in the opening of a new mine, where there are no developed mines in the neighborhood to give an approximate index of the quantity of water that may be encountered, is to sink the shaft, bailing as long as it is economy to do so. When this is no longer practicable a sinking pump is put in, and this should have a capacity three or four times greater than the amount of present water requires. Calculation must also be made for an increasing lift as the shaft goes down. When this first pump is approaching the limit of its capacity, as to volume of water or height of lift, a second and larger pump is put in, and sometimes both the old and new pumps may be employed to advantage, each lifting its own load to the surface or drainage level or they may be used in stages. By adding pumps from time to time as necessity demands, the shaft is carried to its deepest point, or to a level at which it will remain for a period of years. The levels are opened, sometimes contemporaneously with the sinking of the shaft, as is usually the case where the shaft is in or near the vein, or the levels are driven later, as is generally the case when a shaft is sunk vertically to cut a low-dipping vein, as in the deep levels of the Rand mines. When the maximum flow of water has thus been practically established, it is economy to put in a single large pump to raise all the water at a single lift, in place of several smaller pumps at various levels, or, at least, as few pumps as may be required to handle all the water. Twenty to thirty years ago large Cornish pumps were commonly installed at great expense to raise large volumes of water to great height, but in more recent years it is generally deemed better economy to employ modern steam, electric, hydraulic or air-driven pumps, raising by direct and, where possible, by single lift, all the water. As to a choice between these various types of pumps, the surroundings of the mine usually determine this. Where fuel is high, electricity, or air compressed by electric power, is often more economical than steam pumps. If water be abundant and cheaply obtainable under high head, a hydraulic pump may be preferred. Each of the four types mentioned are effective and satisfactory under conditions suited to their use. The Cornish system is also effective when once installed, but it is a system of small flexibility. Should the amount of incoming water be suddenly increased beyond the capacity of the Cornish pump to control, its one chief advantage becomes at once apparent—it can not be drowned out; but should it require repairs, they can not be made under water any more than on any other kind of pump. The expedient of "hooking" two Cornish pumps onto a single rod has been successfully done, but at an extreme risk of breaking the pump rod, usually a heavy and expensive construction. Also the employment of two rods in a single shaft compartment is not an unknown condition, but such installations are both expensive and unsatisfactory. Some of the rods operating Cornish pumps are of great length and size. That in the Combination shaft of the Comstock lode at Virginia City, Nev., was 3000 feet in length and 15 inches square. It operated a double line of 15-inch plunger pumps at a maximum of 6½ strokes per minute. A pump of these dimensions contains over 50,000 feet of timber.

The hoisting of water with skips and buckets is a common practice throughout the mining regions of the United States, and it is a method which may be adapted to any condition where the shaft permits the rapid and unobstructed passage of skips or buckets. Where the amount of water encountered is very large it may be necessary to have a shaft exclusively used for bailing, but ordinarily a single compartment of a three or four-compartment shaft, equipped with a large automatically operated bailing skip, can lift a very large amount of water from any depth to which shafts have been sunk (5000 feet), at a cost comparing favorably with other methods of raising the same amount of water to an equal height.

R. V. Norris in Cassiers for May makes the statement that at a Pennsylvania anthracite mine a skip of 1300 gallons capacity raised 780,000 gallons of water from a depth of 1000 feet in twelve hours daily, making fifty trips per hour.

At the Utica (Cross) shaft, Calaveras county, Cal., the bailing skip has a capacity of 1500 gallons and lifts water from a depth of 1300 feet, easily controlling the water in a wet mine.

Whatever means be adopted to raise the water from a mine, there is no economy in installing a mine drainage plant with insufficient power. This is a matter which requires as mature consideration as the determining what means shall be employed to raise the water.

WITHIN the week a distressing and most unfortunate accident is reported as occurring in the Robinson mine near Johannesburg, South Africa, in which forty-three native laborers were killed by the falling of the cage 1000 feet to the bottom of the shaft. Details of how the cage came to fall are not given in press dispatches, but it again emphasizes the necessity for daily trials of the safety appliances on mine cages.

CONCENTRATES.

CHLORINATION TAILINGS would make an excellent flux in the smelting of galena, insuring a recovery of all the possible gold therein.

****

SARDONYX is a crypto-crystalline variety of quartz which is like onyx in structure, but includes layers of carnelian (sard) both dark and light colored.

****

IF fireclay cannot be procured the muffle may be repaired by using a mixture of one to two parts of litharge, ten parts of boneash, made up to a paste with water.

****

BY volcanity is meant the state of being volcanic, or of volcanic origin, and it is used as descriptive of the evidences of volcanic action as seen on the surface of the earth.

****

IT would be possible to reuse water once used in stamp mill operation by means of receiving tanks and allowing sufficient time for pulp precipitation and complete clearing of the water.

****

BORAX is soluble in water, but calcium-borate, from which most of the borax of commerce is made, is not, but is soluble in hot hydrochloric acid, with separation of boric acid on cooling.

****

DYSCRASITE is a silver antimonide, including Ag_3Sb (Ag = 72.9%) and Ag_6Sb (Ag = 84.3%). It is sectile, color and streak silver white, sometimes tarnished yellow; specific gravity, 9.5; hardness, 3.5.

****

SIBERIA'S yearly gold production averages about 1,100,000 ounces, and it is unlikely that the present war will have any lessening effect. Scientific methods and modern American machinery could greatly increase the Siberian gold output.

****

NORTHUPITE is a double chloride and carbonate of sodium and magnesium ($MgCO_3$ Na_2CO_3 NaCl), crystallizing in isometric octahedrons; color, white to yellow or gray. Its only known occurrence is at Borax lake, San Bernardino county, Cal.

****

THE deepest oil well drilled in the United States is reported to be one of those of the Forest Oil Company of West Elizabeth, Pa., which is said to be 5575 feet deep, or 637 feet deeper than No. 5 shaft of the Tamarack copper mine, near Houghton, Mich.

****

A SEVEN PER CENT. grade and a 7° grade are not synonymous. By a 7% grade is meant a rise of 7 feet in each 100 feet horizontal distance. A 7° grade will make a rise of 12.28 feet in each 100 feet of horizontal distance, or about 648.38 feet to the mile—a steep grade for heavy teaming.

****

THE strength of hoisting cables is proportional to the area of the circle described by the diameter of the rope. A factor of 6 is usually allowed for safety—that is, if a rope is required to sustain a maximum load of 8000 pounds, the rope should have a breaking strength of 48,000 pounds.

****

WHEN cupelling, if too high a heat be employed, a portion of the precious metal will be volatilized, and a portion will be absorbed by the cupel, thus rendering the result unreliable. It is equally bad to have the heat too low. Experience soon teaches the proper temperature to employ.

****

CORD WOOD may be used to advantage in lining up mill holes in the form of a crib. A chute lined in this manner is not long-lived, as the wood cuts out rapidly, particularly if the ore is drawn out as fast as it is shoveled into the hole. If allowed to fill, there is always danger of jamming.

****

"BRITTLE SILVER" is the mineral stephanite, an antimonial sulphide of silver (Ag_5 SbS_4); color and streak are iron black; specific gravity, 6.2; hardness, 2—2.5; fracture, uneven; before the blowpipe on charcoal fuses, coats coal with antimony oxide; yields globule of metallic silver. Silver = 68.5%.

****

OCHER is the earthy variety of ferric oxide—usually applied to earthy limonite, brownish yellow to yellow in color. It is often impure from the presence of clay, sand, etc. When clean, it is used for making paint. Red ocher, ruddle and red chalk are applied to the earthy varieties of hematite, the anhydrous oxide.

****

THE specific gravities of the principal precious-metal tellurides are as follows: Sylvanite (gold-silver, in proportion 1 to 1), 7.9 to 8.3; calaverite (gold : silver = 6.5 : 1), 9.04; petzite (silver : gold = 3 : 1) 8.7-9.02; hessite (silver telluride), 8.31-8.45; nagyagite (sulpho-telluride of lead and gold), 6.85-7.2; krennerite (gold-silver), 8.35.

****

ALKALINE SULPHIDES in cyanide solutions retard its work in gold extraction. Where pure 1% cyanide solution dissolved a given weight of gold in ten minutes, a solution of the salt of the same strength, but containing one one-hundred-thousandth part of sulphur as an alkaline sulphide, required two hours to dissolve the same weight of gold.

THE price for molybdenum quoted elsewhere herein is the New York retail price for the metal, and not for molybdenite, the sulphide. Those who have molybdenum ores for sale should not expect to receive this price for their mineral, nor for the metal after it is extracted from the ore, as metal dealers do not sell their wares at the purchasing price.

****

BROADLY SPEAKING, an "ore" is defined as a natural mineral compound containing one or more metals. Strictly, it is applied only to those from which the metal can be produced at a commercial profit. For example: Chalcopyrite (copper pyrites) is an ore of copper but not of iron, though it contains nearly as much iron as copper (Cu, 34.5%; Fe, 30.5%). Pyrite contains 46.6% iron, but it is not considered an iron ore. The term is sometimes also applied to non-metallic minerals, as a "sulphur ore."

****

THE decay of the telegraph pole is caused by the growth of fungi in the wood. The pole first decays at the surface of the ground, or just below the surface, because above the ground the wood has a chance to dry out, and down in the ground there is not enough air for the fungus to flourish. The subject is an extensive one, and a full discussion can be had by writing to Dr. Von Schrenck, Bureau of Plant Industry, Department of Agriculture, Washington, D. C., and asking for his bulletin No. 14, 1902, on "The Decay of Timber, and Methods of Preventing It."

****

PENEPLAIN (from the Latin, meaning "almost a plain") is a geological term indicating a region of faint relief—that is, a region where denudation has reduced the surface to such an extent that further erosion would result in a "base-leveled" plain. If, subsequently, a regional uplift takes place and a new drainage system is established, a view on a level with the tops of the flat ridges thus formed will have the appearance of a peneplain. This feature can be seen in the Sierra Nevada mountains of California, where the peneplain has about a 1° slope from the horizontal toward the west.

****

THERE are ten electrolytic copper refineries in the United States; Great Britain, 6; Germany, 9; France, 4; Austria-Hungary, 2; Russia, 2; total, 33. The world's average daily production of electrolytic copper is about 883 short tons, of which 764 tons, or 86.5%, are supplied by the United States. Of the remaining 119 tons daily production, or approximately 13.5%, Great Britain furnishes 8.5%, Germany, 2.5%, and France 1.5%. The United States now produces annually 280,000 tons of electrolytic copper, which, at $250 per ton, is valued at $70,000,000. The by-product recovered daily contains about 740,000 ounces silver and 950 ounces gold, which equals an annual output of 27,000,000 ounces of silver, valued at $14,000,000, and 250,000 ounces of gold, valued at $5,167,500.

****

IRON can be prevented from rusting by the application of a strong solution of potassium bichromate, the article to be subsequently dried in an oven or over an open fire. Drying at ordinary temperatures will not be sufficient. To know when the heat is strong enough, moisten the iron with a little water. So long as the iron takes up any color the heat must be increased. When the requisite degree of heat is reached a fine deep black color results, which is not acted upon by water and which protects the surface of the iron from the action of the atmosphere. To remove rust from instruments, tools, etc., fill a suitable basin or jar with a saturated solution of tin chloride in distilled water. Immerse the rusty instruments and let them remain over night. Rinse in running water and rub dry with chamois.

****

A MIXTURE of one part niter and three parts argol (deflagrated) is sometimes employed in assaying. It is known as "black flux." A mixture of flour, three parts, and sodium bicarbonate, ten parts, is known as a substitute for black flux, and is used in place of lead flux, which latter is a mixture of sodium bicarbonate (sixteen parts), potassium carbonate (sixteen parts), flour (eight parts) and borax glass (four parts). It acts as a flux, reducing agent and desulphurizing agent, and is particularly useful in assaying lead, and for this reason is known as lead flux. What is known as Chapman's crucible flux is composed of carbonate of soda one and one-half part, dried borax one part, cream of tartar (argol) one-eighth part, white sugar one ounce, with a proper amount of litharge, usually from one to five times the weight of the ore, according to its character.

****

THE principal advantage in using the dovetail style of timbering in framing shaft sets is in the fact that that method requires less timber than in the overlapping ends, framed after the Comstock system. Where the timbers are over 12 inches square, this would make a considerable difference in 1000 feet of shaft. Where the timbers are 12x14 it would make a saving of 56 feet, board measure, on each set; and if the sets were arranged at 5 feet from center to center, in 1000 feet of shafts there would be 201 sets—making a total saving of over 11,000 feet of timber, board measure, which in most Western mining regions would be worth over $200. The long timbers should be bought to cut with as little waste as possible. It pays to buy special sizes for blocking; 10x10-inch timbers are as good as any others for 12x12 sets.

MAGNETIC PYRITES containing 3% nickel and 3% copper are heap roasted at Sudbury, Ontario, Canada. Being first classified into three sizes—4 inches, 1½ inch and ¾ inch—the coarsest is laid upon a bed of wood, over this the intermediate size, and then the whole covered with the fine material. In the center of the heap is a small rectangular vent or chimney to aid combustion. The bed of wood is laid upon a layer of fine ore 6 to 10 inches thick, which usually becomes itself roasted about half way down. The heaps are usually 5 to 15 feet high, 82 feet long and about 39 feet broad. A "heap" will contain from 300 to 600 tons of ore. A cord of wood is allowed to every twenty tons of ore. The length of time required for roasting varies from thirty to sixty days. One roasting will reduce the first proportion of 30% sulphur to 4%, and of 40% sulphur to 7%.

****

THE sudden influx of a large amount of water into mine workings is due to cutting a water course connected with a subterranean reservoir. The reservoir need not be an open excavation or a natural cavity in the rocks, but may be a zone or irregular body of fractured porous rock. Often when first cut the water gushes out with great force, but this usually soon disappears, and the stream assumes a normal flow. Until this normal flow is reached it is difficult to determine the capacity of the pump required to handle the water, but it is wise to put in a pump considerably larger than seems necessary, for if it handles the water readily it can run slowly, and should a large flow be again encountered the pump will probably be able to care for it. There is no economy in buying machinery which must soon be thrown out to be replaced by that of greater capacity.

****

SPECIFIC GRAVITY is the ratio of weight of a substance (solid, liquid or gas) to the weight of an equal volume of another body which is used as a standard. The specific gravities of solids and liquids are referred to pure water at a temperature of 15.5° C. In the case of gases the standard must be at same temperature and pressure. Gases are usually referred to pure dry air either at 60° Fahrenheit and 30 inches barometric pressure, or 0° Centigrade and 760 mm. barometer; though in theoretical chemistry the standard is usually hydrogen instead of air, as the atomic weights are also referred to hydrogen as the unit (making, in the case of the elementary gases, their atomic weights identical with their specific gravities—e. g.: Oxygen specific gravity = 15.88 with hydrogen = 1). In this connection it may be stated the specific gravity (H = 1) of a gas or vapor is the weight in grams of 11.11 litres of it. To determine specific gravity of a gas, especially designed apparatus is necessary. For solids: Weigh the body in air, then weigh while suspended in water (balances are necessary for these weighings), and difference in weight is weight of equal volume of water—specific gravity = wt. water ÷ wt. body. For liquids: Weigh a flask filled first with the liquid and then with water, and subtract from both the weight of flask.

****

MANGANESE is not known to occur native; it most commonly is found in nature in the form of black oxide (pyrolusite or psilomelane). In gold and silver mines, particularly the latter, it is of common occurrence. On the surface it is found as black oxide, and often in depth it is seen as carbonate (rhodochrosite) or as the silicate (rhodonite). It is rare to find it as sulphide, which, as is the case with most other base metals, is the normal condition; but the sulphide exists, and it is probable that all manganese oxides, carbonates and silicates were originally sulphides. The sulphide of manganese is an iron-black mineral of high specific gravity, having a greenish streak. It is called alabandite and is an uncommon mineral. It occurs at Tombstone, Ariz., associated with silver ores. It was found in limestone near contact with grano-diorite. Manganese oxide occurs abundantly at Leadville, Colo., in the oxidized zone; also at Butte City, Mont., and at Broken Hill, New South Wales. It also occurs in other countries, often as an ore of manganese alone, with neither silver nor gold. It is found mostly associated with limestone or cherty (siliceous) rocks, though occurring elsewhere, but usually in less amount than in limestones or cherts.

****

THE main geological eras or groups, with their principal divisions, are as follows: Archæan, Algonkian, Paleozoic (Cambrian, Silurian, Devonian, Carboniferous), Mesozoic (Jura-Trias, Cretaceous), Cenozoic or Tertiary (Eocene, Neocene, Pleistocene), Quaternary or Recent. The Archæan was formerly divided into Laurentian and Huronian in the United States, but the Huronian is now included with the Keweenawan in a new group called the Algonkian, which is pre-Cambrian. The lower Silurian in England is designated Ordovician. The Permian is an age of the upper Carboniferous. The Jurassic and Triassic divisions of the Mesozoic, though distinct in their characteristics, are not sharply separated by unconformities, and so are usually included in the compound name Jura-Trias. The Pleistocene of the Tertiary is separated into glacial and post-glacial stages. The Quaternary or Recent covers the human epoch. The Cambrian, Silurian, Devonian and Carboniferous are the principal ore carriers of the world, though the ore bodies themselves are not contemporaneous with, but later than the formations enclosing them. The so-called Mother Lode proper of California is referred to the Jurassic. The mines of the east belt occur largely in rocks of the Calaveras formation, which are of Paleozoic age.

California Mountain Road and Region.

When the Californiа miner is delayed for weeks by lack of transportation facilities he sometimes envies his brothers in less mountainous countries who can secure quicker service. The State of California, through its department of highways, is in present activity in commendable effort to give miners and others in isolated districts badly needed roads. There is in present progress a State highway to connect the main portions of the commonwealth with the part lying east of the Sierra Nevada mountains, comprising three counties, Mono, Inyo and Alpine, the road passing through the heart of the Sierra Nevada mountains. It makes use of "the old Tioga road, which a mining company constructed over twenty years ago," at a cost of $64,000. It took out from the Big Oak Flat road at Crockers, in Tuolumne county, and extended 56 miles by way of Lake Tenaya and Yosemite creek, passing only a little east of the Yosemite valley to a point 9800 feet above the sea level, where the mines are situated, while around about are elevations vastly higher. Adjacent are the towering granite peaks, Mounts Dana, Gibbs, Conness and Lyell, rising to altitudes above 13,000 feet and bearing on their northern slopes the remains of great glaciers, which once covered immense areas over this grand mountain complex. Granitic boulders, many of huge size, are scattered everywhere over the surface.

The engravings herewith illustrate the style of country through which this highway is being executed by the State, using the old Tioga road as a part of the enterprise.

One of the scenes is on the survey of the Tioga State road in Mono county. Mount Tioga, which is shown in the middle background, has an altitude of 11,000 feet; the road at this point has an elevation of 9000 feet above sea level, and here must be constructed through crevіced granite and is to connect that part of California included in the counties of Alpine, Mono and Inyo, east of the Sierra Nevada mountains, with the principal points in California by way of the Yosemite and the San Joaquin valley. At present the only commercial outlet for the people of the counties above named is by way of the State of Nevada.

Another illustration shows the broken talus of granite, averaging in diameter about 2½ feet. The road over this is to be of 7% maximum grade, and is to be walled on both lower and upper sides.

A third illustration shows the great angular boulders of granite near Mount Parker, such as are sometimes encountered on the line of mountain roads.

The fourth illustration shows a scene of less rugged grandeur, indicating that the extreme difficulties of construction are not always present. The picturesque little lake, like the most of the lakes and meadows of this Sierra region, is of glacial origin, though in some instances they are the result of damming of the valleys by recent flows of andesite or basalt.

The inaccessibility of the crest of the Sierra Nevada mountains has delayed the development of the mineral resources of that elevated region, though it is well known that at various places along the summit of the range and near it there are great veins and ore deposits, though mostly, as far as known, these ores are base—that is, not free milling, being complex mixtures of the sulphides of iron, zinc, copper and lead, with gold and silver. Considerable prospecting has been done near the headwaters of the North Fork of the San Joaquin river, in the northeastern part of Madera county, at an altitude approximating 8000 feet. In that district is a system of nearly parallel quartz veins, most of them of large size—15 to 75 feet in width—and traceable for several thousand feet. Shipments of selected ore are said to have carried 30 to 40 ounces silver, 17% lead and $2 gold per ton. One vein assayed 30% copper and 27 ounces silver per ton. All of these veins have only prospecting development, and only lack of suitable transportation facilities retards their development. At Mount Raymond, a few miles southwest of this district, are mines containing lead, zinc, iron and copper sulphides, with gold and silver values, and to the eastward of North Fork district are the great iron deposits known as the minarets. About 15 miles to the northeastward of the North Fork district are the mines of Tioga district, through which the road above referred to will pass. This district is on the summit of the Sierras, at an altitude of nearly 9800 feet. Bodie is 25 miles distant in a northeasterly direction. Bennetville is the name of the village that once was the center of the mining industry there, which perished for lack of transportation facilities in that rugged mountain region. That portion of the road above referred to as being completed was made at an expense of $64,000 by the Great Sierra Mining Co. in 1882-83. The principal development in this district is on the Great Sierra and Sheepherder lodes. Crosscut tunnels were driven to reach the veins at a depth of 800 feet, but were discontinued before the veins were reached after running over 1000 feet, and with less than 300 feet to go.

The veins occur in highly tilted and folded metamorphic rocks (slates and quartzites) and partly in gneiss. The lodes are large—10 to 45 feet wide—and of great continuity. The gangue is white, crystallized quartz. The minerals contained are described as argentiferous and auriferous mixtures of pyrite, chalcopyrite, zincblende, with subordinate occurrences of galena, bornite and arsenical iron sulphide (mispickel). The gold values are said to run from $1 to $8 per ton. No metallurgical operations have been carried on in the district.

In addition to the districts previously described are those of the region about Mammoth, in Lake district, near the North Fork district. The veins here are said to occur between porphyry and quartzite. The ores here also contain iron, lead, copper and zinc sulphides, with the secondary products of their alteration and both gold and silver. The bullion varies from $7 to $16 per ounce, dependent on the amount of silver present. In the early history of the district it is reported that about $20,000 worth of ore was shipped from the Mammoth mine. This mine has opened a vein 15 to 40 feet wide by means of tunnels. A 20-stamp mill was built on the mine in 1878 and twenty more stamps added in 1879. Only free gold was saved from these ores, and no attempt was made to concentrate the ores, which is the real road to success in mining in this region. Samples panned from the tailings are said to have returned a good percentage of sulpurets, high in gold and silver. The tailings have since been run over canvas sluices and a rough saving of the sulphides made in that manner.

In addition to the districts already mentioned in the high Sierras are Lundy, Pine City, Patterson district, north of Bridgeport, the Keith district, formerly part of the Mono diggings, the Jordan district and others, both north and south of those described. The only drawback to the development equipment and successful operation of these mines is cheap transportation, for there is abundance of wood and water. Many of the veins can be worked to the depth of several hundred feet by tunnels and the climatic conditions are less severe than those of the Rocky mountain region of Colorado. In the latter State several of the principal mining cities are at a greater altitude than any of the mines here referred to. But in Colorado, when mineral resources are shown by miners to exist, the enterprising railroads of that State quickly make the region accessible by building into the district.

In California the mining community has been spoiled by having the greater number of the mines developed in a region of gently rolling hills, where

Broken Talus of Granite on Leevining Creek Canyon, Near Tioga Mines.

A Spur of Mt. Parker on Tioga Road.

snow seldom falls, or quickly disappears, should it come, and where the difficulties of transportation offer no material drawback to the development and operation of the mines. These mines are for the most part not above 1500 feet altitude. Outdoor operations can be carried on throughout the year, and the cost of mining has been reduced to the lowest possible figure. Men accustomed to such conditions do not look with favor upon a mine situated on or near the summit of a great mountain range, which is mostly covered with snow throughout the year; but in Colorado the miners are used to this, and abundance of snow to them means abundance of water in the summer season, and this is synonymous with prosperity.

Near the Summit, Tioga Road.

Mount Tioga—Road Survey Around Left-Hand Side.

ANY metallurgical process, whether patented, secret, or otherwise, for which it is claimed that a greater value can be extracted from ores than is indicated to be present by assay, may be safely looked upon with suspicion. The methods of determining the amount of metal contained in ores, by either fire or wet analysis, have been reduced to an exact science, and, processes operating on a commercial scale by which it is claimed the operator can produce more than is indicated by these searching methods of assaying, is pretending to produce something from nothing—a physical impossibility.

Iron Ore in the Uinta Mountains, Utah.

In a reconnaissance study of the general geology of the region lying east of the Wasatch Range, Utah, J. M. Boutwell of the United States Geological Survey recently visited deposits of red iron ore (hematite) and obtained geological data concerning that region. In a short article published in the Survey's Bulletin 225, entitled "Contributions to Economic Geology, 1903," Mr. Boutwell presents the essential facts learned about these iron deposits of the Uinta mountains.

The Uinta Range is in the northeastern part of Utah, but it extends also into the extreme northwestern part of Colorado, immediately south of Wyoming.

In about the latitude of Salt Lake City and the southern shores of Great Salt Lake, it reaches from the Wasatch Range eastward approximately 150 miles, with an average width of about 35 miles. The range is in the form of an elongated dome composed of a deeply dissected central plateau and encircling hills. The iron deposits described by Mr. Boutwell occur in limestone near the inner margin of the belt of encircling hills, and thus outside of the interior plateau region. The narrow divide in which they occur overlooks eastward the broad glacial amphitheater of the upper Duchesne and its canyon, and westward the corresponding amphitheater of the basin of Soapstone creek. The locality is easily accessible from the west by way of Provo river and Soapstone creek. It is reported that the continuation of the same route leading by other deposits, farther south, may also be taken from the Duchesne on the east.

The iron was probably discovered and first used by the Indians, who are reported to have looked with favor on it as a source of paint. About twenty-five years ago the most promising deposits were located by a party from Heber. It is believed that they did the first actual development work on the property and hauled a few loads of ore to the smelters in Salt Lake valley. It is known that shipments were made amounting in all to at least 500 tons. About 1882 the ground was surveyed for patent, and seven claims, each 600x1500 feet, were eventually patented by E. P. Ferry. Some further prospecting has since been done in the vicinity, and, as a result, a few more claims may have been staked. In the fall of 1902 other croppings were prospected, additional claims were laid out and some assessmeet work was done.

The ore is a red hematite of two varieties—the red of the ocherous and the gray of the massive, semi-specular type. It varies in purity from samples of high grade, which are solid, pure iron oxide, to those in which the barren country rock in closes mere patches of lean ore. An analysis of a selected sample of a high-grade massive, semi specular variety reveals not only a high content of iron (79.34%) and a suitable amount of silica (18.55%), but also a most desirable absence of the deleterious elements — titanium and sulphur—and only a trace of phosphorus. It indicates a high-grade, workable iron ore. So little development work has been done, however, that there is meager basis for estimating its quantity.

A surveyor who ran a line for a railroad through this region in the early days reports an extensive body of iron, apparenty on this same divide, several miles to the north, and others state that promising outcrops occur to the south along this divide at intervals of several miles. A good wagon road, now out of repair, was built in the early '80s from the main road along Provo river up Soapstone creek, past a sawmill, to the ore pits at the crest of the divide. At present the nearest railroad point is Park City, about 35 miles west. Standing timber is plentiful and a small creek flows across the property. If, on thorough investigation of these deposits and the others reported to occur in the vicinity, it should appear that the amount of ore warranted operation of the property, the chief problem would be that of transportation.

Interesting Smelting Operations.

A smelter operator in Mexico says: "Our ores carry one-half of 1% copper, and consequently our matte is low in copper, but rich in gold, with some silver. We have found that one-fourth of 1% copper is sufficient to collect all the gold and silver, and this amount pays freight and treatment charges. In the furnaces hot blast is supplied by waste heat from the boilers and furnaces. About 15% of pyrite is used in the charge. The amount of coke used varies with the quantity of pyrite used, and other variations in conditions. A monthly run showed that an average of 7% coke was employed. Coke is freighted 60 miles and costs $20 gold per ton. There is little flue dust. The ores are dumped directly into the furnace as they come from the mine, breaking up the largest lumps only. No extra lime or other flux is required, the ores being self-fluxing when suitably mixed. The slags are very clean and carry from 40% to 45% of silica and insoluble mineral; iron 25% to 30% and lime 3% to 5%, but no lime is necessary. A silicate of iron slag is considered good enough, and so is iron matte, which runs 55% to 56% iron and 27% sulphur. The losses in the slag are small, and the labor at the furnaces light."

THE year 1903 stands as the high-water mark of prosperity in the anthracite coal trade, as the tonnage for that year exceeded by more than 6,000,000 tons that of any previous year, and the demand for coal was so good as to make it possible to dispose of the product at prices which brought a fair return to all concerned in the industry. Some significant figures in connection with the production of Pennsylvania anthracite during 1903 have been collected by W. W. Ruley, Special Agent of the United States Geological Survey, and will be included in E. W. Parker's report on the production of coal in 1903, which is a regular feature of the Survey's annual volume on the Mineral Resources of the United States.

CYANIDE OF SODIUM is becoming a competitor of 98% cyanide of potassium in cyanide practice, it giving favorable returns in cost and results.

Mill Construction, Milling and Amalgamation.*

Written by I. ROSKELLEY.

Like all other machinery and processes in vogue for the recovery of gold on the Witwatersrand, the mill and milling practices of to-day have been gradually evolved out of ruder machinery and cruder methods. Despite the improvements that have been made, the millman still finds many details in mill construction which could be changed with advantage both to economy of working and to the life of the mill. Engineers have already recognized many of these defects, and nothing but the cost of installation has prevented them from being rectified, and in the numerous new mills in course of construction will see them remedied.

Before treating of milling, I will point out a few of the alterations which, I consider, would materially improve our mills:

1. Lack of adequate space is, I am sure, a serious defect in most of our mills. Sufficient space should be allowed at the end of the mill for men to reverse the ends of a cam shaft. Usually, we find barely enough for them to range up to carry it. The cam floor, too, is much too narrow for the rapid working which breakages demand if the output of the mill is not to be lowered.

2. Then, again, instead of being provided with one tackle block carriage or overhead crawl, a mill should have four—one over the stamps, as is usual, another over the cam floor and two others at right angles to these, one at each end of the mill, so that parts needing repairs or renewing can be readily brought into position from the door of the mill.

3. The keyed cams and shafts in general use now can be advantageously done away with in favor of the new self-tightening cams. With the former, mill men find it difficult to tighten a loose cam—and they are continually working loose—because they can not get at the key, owing to the adjacent cam. In case of breakage, stamps have to be hung up an unnecessarily long time, since all cams from the end of the shaft to the broken one have to be loosened and again keyed up. In the new cams the entire cam hub, by its self-tightening construction, takes hold upon the shaft, and dependence is not to be placed on the shearing stress of a key, which is liable to work loose, or which may be driven so tightly that it may split the cam or impair its strength. Taking off the new cam is a simple and rapid operation. A slight blow on the back edge with a hammer loosens the cam so that it can be slipped off. Where these cams and shafts are in general use, breakages can be remedied in less than quarter the time taken with the old style, and mill operators would not be troubled with loose cams.

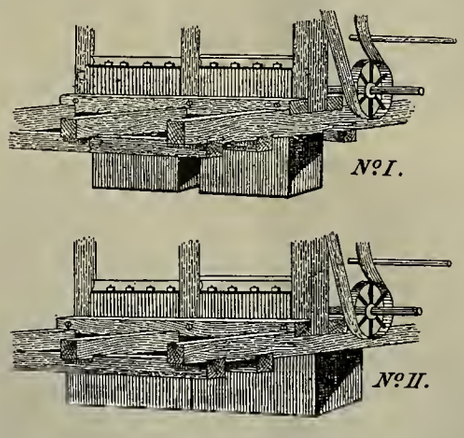
4. In modern mills ten stamps are usually placed on one shaft, and, as long as things are running smoothly, this seems a good arrangement, since less timbering, pulleys and belts are required than with five stamps to a shaft. The economy in timber is, however, slight—five king posts instead of six—and pulleys and belts have to be proportionally heavier for their heavier duties. This slight gain in initial cost is, in my opinion, more than counterbalauced by the excessive loss of time and waste of labor in repair of breakages, and for this reason I advocate a return to the old-fashioned five stamps to a shaft. The disadvantages of the present arrangement when anything goes wrong are that (a) ten stamps are held up instead of five while repairs are being done, and, (b) if the breakage occurs near the pulleys, some seven or eight cams instead of three or four have to be taken off and put on again, unless the pulley is taken off, and this is often a very difficult job. Hence, twice the number of stamps are held up for about half as long again as would occur were there only five stamps to a shaft.

It may be urged that I am thinking of nothing but breakages, and that these do not occur as often as I would imply. But repairs of one kind or another have to be made daily, and in the construction of a mill this should be borne in mind and everything done to facilitate it. Besides, when men are working at repairs, the rest of the mill is being neglected, and a broken stem or screen may pass unnoticed for some time.

5. In building a mill much care should be given to the selection of timber, especially to that which is used for king posts (battery posts). Good, well-seasoned pitch pine should be used for this purpose; unless this is done, splitting and shrinking and consequent loss of strength will occur, owing to the vibration. In many mills little attention seems to have been given to king posts, although they have to bear the brunt of the work. Where ten 1250-pound stamps are run to a shaft, the king posts are often the same size as those used in light mills, where five 1050-pound stamps are run. A cross-section of these posts measures 12x23 inches, but 18x23 inches would be better. The usual foundation of king posts is not good, as it admits of considerable vibration, that can be avoided by giving it a solid support, as shown in the following diagram.

This can be done by continuing the blocks that support the mortars outwards, so that the streak sill on which the king posts rests is supported by them directly beneath the king post.

Other points in mill construction I will leave until I come to the working of the mill, when I shall have something more to say on the point. When ore is brought up from the mine it is classified into "fines"



and coarse rock by dumping the skip load on a grizzly. Theoretically, "fines" is rock that passes through about an inch gauge, but, practically, it is often very different. I have seen rock weighing a stone (fourteen pounds) getting into a mill as "fines." The bars of the grizzly get worn or bent, and occasionally one falls out, hence the presence of these coarse "fines" in the ore bins. The grizzly should be examined often and anything defective rectified immediately winding ceases. Careless workmen and worn machinery here and in the crushing house are responsible for numberless breakages in the mill and for a low crushing capacity.

SORTING.—Since Mr. Johns introduced sorting on the Ferreira mine, in 1892, it has become geueral along the Rand; but since crushing has been resumed after the war scarcity of native labor has compelled the managers to sort less, and hence the grade of their ore has been lowered. H. H. Webb, in his address to the South African Association of Engineers, has, I think, put the question of sorting in a nutshell. "Sorting," he said, "will bear investigation for each individual property, at least, to find the desirable percentage of quartzites to be eliminated."

CRUSHING.—Usually. the crusher is supposed to break rock to about 2-inch cubes; but it is often coarser, owing to worn machinery. The tonnage crushed in the mill could be materially increased if the rock brought into the bins was first reduced to 1-inch cubes, since the drop could be lowered and the speed increased. Much more attention must be given the ore coming from the mill if we would get that rapid and effective crushing which is aimed at.

CONVEYING ORE TO MILL.—After passing through the breakers the ore is delivered to the mill bins by belts or mechanical haulage. The latter is the more usual, but where belts are used they give very satisfactory results. A Robins belt conveyor has been in steady use on the Robinson Deep for about twelve mouths, carrying from 700 to 1000 tons of ore per day to the bins, with no sign of undue wear. The belt, which is 24 inches wide, is made of canvas thickly coated with rubber, the center part being thicker than the sides.

The ore is tipped from the belt into the bins by means of a tripper. Just behind the point of tipping the makers supplied a brush which was intended to sweep off any particles of sharp rock adhering to the belt. This the brush failed to do effectively, and the result was that in passing over the supporting rollers on the return journey they were forced into the rubber.

The brush has been discarded for a stream of water from an inch pipe, acting at the point where the brush was placed. The water is brought up by a simple device. A long hose is attached to a water pipe outside the mill and brought in over a roller through a small window on a level with the tripper. As the tripper is moved backwards or forwards in the mill, the hose coils or uncoils automatically around a wooden cone placed directly beneath the window. The belt is cleared of water by a rubber scraper, placed a little in advance of the hose pipe, and the water is conveyed down through inclined launders to tanks, where the particles of ore settle.

FEEDERS.—Ore is fed into the mortar box by an automatic feeder. The feeder is operated either by a tappet rod or by a forked level, which engages a feed collar placed on the central stem of the battery. Many attempts have been made to improve on the Challenge feeder, but the two or three so-called improved feeders I have seen at work certainly do not justify discarding it. Probably an improvement will be made so that the brake wheel and three pawls can be done away with.

THE STAMP.—(a) THE STEM.—Hard, fine steel is the material of which stems are made, but after from four to six months' wear they often snap right above the head. It occurred to me that, to get an ideal stem, two materials should be used—hard, fine steel for the center part, where, with more pliable, though tougher material, bending would occur; and a tough iron for the upper and lower parts, where bending never occurs, but where the stem often snaps.

Acting on this idea, I had some 3 feet of iron welded to both ends of an ordinary hard steel stem and tried that. I have had about a dozen of these iron and steel stems in constant use for about eight months, and up to now I have not had a breakage with them. Though I can not as yet speak definitely as to the life of these stems, I consider them an improvement on the usual hard steel ones. Coarse steel, however hard, gives very unsatisfactory results. A number of stems of this material broke in the middle in the Robinson Deep mill after only two weeks' work.

(b) HEADS.—These should be made of hard, fine, cast steel. The difficulty which millmen experience with heads is the driving out of the broken stem. Often he has to resort to dynamite, and the chances are that he splits the head with the charge. This difficulty is one which occurs in large mills daily, but a slight alteration in the construction of the head would do away with it altogether. Between the end of the shankway of the head and the end of the shankway of the stem there is at present a solid center of from 2 to 4 inches. If the makers supplied heads with a 2-inch or 2½-inch hole through this part, the difficulty could be overcome. This alteration having been made, the stem would be driven out by placing the head with the broken stem downwards and giving the stem a few blows with a hammer worked by steam or compressed air. The small hole through the center would not materially weaken the head. At present blasting is about the only thing that splits them.

(c) SHOES.—Battery shoes should be made of hard steel from bottom of shank to bottom of shoe. The shank itself should not be as hard as the remainder of the shoe, as it would be liable to snap if it were. To get this difference in tempering of the two parts, the shoe itself, after being heated, should be cooled rapidly in water, leaving the shank above water to cool slowly. A new 12-inch (high) shoe weighs 225 pounds, and a worn out one weighs from 35 to 40 pounds. The shoe can be safely worn down close to the shank. A shoe will run for about ninety days and crush from 450 to 500 tons of rock.†

(d) DIES.—Great care should be given to the tempering of dies, as, owing to their stationary position, uneven tempering causes uneven wearing, and the result of a badly woru die is diminished crushing, and, possibly, a broken stem. It will be found on examining a heap of worn out dies that, although many of the dies are worn down at the center, some 2 or 3 inches still remain around the edges. The mistake that is made in the manufacture of dies lies in the heating, not in the cooling. A block of steel to be tempered evenly should be heated slowly, so that the whole block has a chance of getting to the same temperature. If the block is heated rapidly, the outside is ready for forging long before the iuside, and when the unevenly heated block is cooled in a bath the outside becomes hard, while the inside remains soft. If the die has been heated slowly and thoroughly, it can be cooled rapidly or slowly, according as a hard or medium hard article is required.

A 6-inch die which weighs 120 pounds will wear out a 12-inch shoe, and, consequently, wears for about ninety days and helps to crush from 450 to 500 tons of rock. A fairly evenly worn discarded die weighs about forty pounds; but, if the tempering has been bad, it weighs considerably more.

(e) TAPPETS.—These should be made of fine, hard cast steel. Those made of coarse steel split and become useless. I prefer a three-keyed tappet to a two-keyed one. The bore of the tappet should be $\frac{1}{32}$ inch larger than the stem it has to take. This little precaution will save millmen much hard work and prevent delay when the stamps are held up.

(f) GUIDES.—Many attempts, more or less successful, have been made to improve on the old-fashioned, solid guides. Wood guides in iron frames and many varieties of all-iron sectional guides have been tried, but I have found the solid guides better than any of the so-called improvements. It has been stated that six months is the life of a solid guide; but by keeping the bolts tight I have found them last much longer than this. Solid guides, made of English oak, that were put in the Robinson Deep mill six years ago, are still in use.

(g) WEIGHT OF STAMP.—This varies from 750 pounds in light mills to 1350 pounds in the heavy ones. It has been suggested in the society that compensating weights should be used when shoes, etc., get worn, to keep the mill at constant weight. To keep any particular stamp at constant weight without some such arrangement is, I admit, impossible; but it is easy to keep the average weight of the mill fairly constant.

A shoe ordinarily lasts about three months, so that in a 100-stamp mill thirty new shoes are put in every month, and this keeps the mill at a constant weight.

*Abstract Trans. Jour. Chem. Met. and Min. Soc., S. A.

†This varies greatly, depending upon the quality of the shoe and of the material crushed, manner of feeding, height of discharge, etc.—ED.

(TO BE CONTINUED.)

The Distribution of Placer Gold in Oregon.*

Written by C. W. Washburne.

In Oregon placer gold is limited to areas of the older rocks or to their vicinity. This means to pre-Jurassic rocks in the Blue mountains and to pre-Tertiary rocks in southwestern Oregon. Of course the streams from these areas carry fine gold even to the sea, and it may be detected in their gravels and sands at many places to so great an extent, indeed, that in sea beaches 200 miles from old rocks flour gold is so plentiful that it is supposed to contain fortunes for those who will find a way to save it. But stream gold which can be saved by methods now in use and in paying quantities is limited to the vicinity of old rocks. This is not a theory, but a fact observed during several years of field work in the placer districts of Oregon and during numerous reconnaissances in the Coast and Cascade ranges. It may be clearly seen by picking out the placer mines on Lindgren's map of the gold belt of the Blue mountains, in the twenty-second annual report United States Geological Survey.

The reason for this distribution is not hard to find. The later rocks in the Blue mountains do not contain much gold. The workable veins of the region are in Triassic or in Paleozoic rocks. Gold coarse enough and abundant enough to be worked with profit can therefore not be found in the stream beds where these rocks are covered for any considerable distance by later lavas or sediments. The same reason applies to southwestern Oregon, except that in this region mineralization continued through the lower Cretaceous (Knoxville) and probably into the upper Cretaceous (Chico), but did not continue thereafter, or at most only feebly. In both regions secondary enrichment may have continued to the present day, but primary depositions ceased at the times mentioned.

This explanation is not entirely sufficient, however. That the presence of gold bearing deposits in the rocks does not mean the presence of workable placers in the streams is evident from a study of the Cascades, though, of course, the absence of gold in the rock of any region must always result in the absence of placers. In the Cascades of Oregon and Washington there are many quartz veins which yield paying quantities of gold. The gold is in Tertiary rocks, and its deposition has continued almost to present time. In this case the absence of paying quantities of gold in the stream is due to the slight amount of erosion which the ore bodies have suffered. Since the late Tertiary the canyons of the Cascades have been cut, and in some cases divides have been worn to sharp ridges. More often the dividing ridges are broad and along their summits have approximately the surface of the last lava flows that did not enter the present canyons. In other words, erosion has been slight, being limited to the cutting of the valleys and canyons of the range. The scarcity of stream deposits among the lavas and tuffs of the range shows that previous to the cutting of the present canyons the piling up of volcanic material greatly exceeded erosion. Hence at that time veins were more likely to be covered than to be worn down by weathering.

In the Blue mountains and in the Klamath mountains, which is the name given by the United States Geological Survey to the mountains of southwestern Oregon and northwestern California, comprising the Siskiyous and part of the Rogue River mountains in Oregon, and the Salmon, Trinity and other mountains in California, on the other hand, there has been great erosion since the deposition of the ores. They are composed of pre-Tertiary rocks, and hence include all the gold deposits of southern Oregon. The erosion of the crumpled pre-Jurassic rocks of the Blue mountains probably amounts to many thousand feet vertically. The erosion of the pre-Tertiary rocks of the Klamath mountains must have been almost as great, as Mr. Diller has found evidence that these mountains were once covered by a heavy mantle of Cretaceous strata which has since been almost entirely stripped off. The latter region has been worn down to sea level, and elevated for recutting into its present form, since the deposition of the gold ores. This erosion, to which that of the Cascades is significant, has resulted in the breaking up of millions of tons of gold ore, the streams concentrating most of the gold therefrom within a short distance from its source.

It is a natural deduction from these two arguments that valuable placers will never be found in the Cascades south of central Washington, nor in the Coast range between the Olympic mountains and the Klamath mountains.

The Oregon coast has many deposits of black sand, but they furnish paying quantities of gold in but very few places. The sand is abundant from beyond the California line to Long Beach in Washington, and will give tests for gold at any place. But no miner has yet found a practicable means of working the sands farther north than the mouth of Big creek in Lane county, though reports have been received from B. F. Jones of Toledo, who is successfully working a beach deposit at Otter Rock, Lincoln county, which is north of the point indicated. In 1902 the writer found W. Reynolds saving $2 a day by working between tides with a rocker at Big creek. Mr. Reynolds also showed the writer a vial containing about three ounces of platinum which he had saved in a winter's work. Mixed with the platinum was another white substance, probably iridosmine, which constituted about one-fifth of the mass.

South of the above place gold has been found mined along the beach at innumerable places. At the mouth of Rogue river there are some beach mines that were once among the richest placers of Oregon. The discoverers of the deposits north of the mouth of Rogue river found it profitable to mine them, even though for lack of horses, it was necessary to hire men to carry the black sand on their backs to the top of the terrace back of the beach where running water could be had for washing out the gold. This was in the sixties. Since then these sands, as well as those near Gold beach, across the river, have been practically exhausted, being worked to-day in a most desultory way.

The source of gold in the beach sands is an interesting problem. Miners along the beach believe it has been brought down by streams from back-lying parts of the Coast range, and concentrated on the shore by the waves. They argue that the presence of black sand in these streams supports their view, which is mostly maguetite, and occurs in nearly all the rivers of Oregon which have basalt or other basic igneous rocks on their drainage, and rarely contains more than a trace of gold. In the Coast range it is not known to contain platinum or iridosmine, which are nearly always associated with the beach gold.

We must therefore conclude that the gold has been transported along the coast from the north or from the south. We have already noted the fact that the gold is too fine or scarce in the black sands from Long beach to the coast of Lane county to be successfully worked. We have also noted that the richest sands are at the mouth of Rogue river. South of this stream the sands are not rich and have never been worked beyond the Klamath river.

Competitive Prices on Quartz Mills.

To the Editor:—We are often asked to figure on a first-class up-to-date quartz mill, the intending purchaser stating that he would like to have the mill operated by steam power, and to be furnished complete with all necessary shafting, pulleys, boxes, belts, copper plates, engine, boiler and they may possibly state the weight of stamps they require, but that is all the information generally given, except that they want everything "first-class."

This information is generally given out to several firms in San Francisco, with the request that they submit specifications and the price on same. While a great many of our mining men are able to distinguish between the good and the bad, still many of the parties, who have the final say in purchasing the mill, are men who do not understand the fact that there is a great deal of flexibility in the word "first-class," and are apt to measure everyone's specification with the dollar measure, which is at times very misleading.

We had a peculiar instance of this a few days since, where we were figuring on a flexible specification of the kind mentioned above—the only information given us was that the party wished a 10-stamp concentrating gold mill complete, to be driven by steam power, stamps to weigh 1000 pounds each, rock breaker to have ample capacity for crushing enough ore in ten hours to operate the stamps for twenty-four.

We furnished our usual specifications giving them full weight of stamps, cast steel cams and tappets, forged steel shoes and dies, and mortar which was lined throughout with removable liners; copper plates 5 feet wide by 10 feet long, four concentrators for the ten stamps and 8x12 Blake rock breaker, a 10x12 25 H. P. slide valve engine, a 40 H. P. horizontal tubular boiler, heavy counter shaft and 12-inch five-ply main belt from engine. In short, we figured up what in our judgment was the very best mill we could produce.

We submitted for same a detailed specification, giving exact weight of the stem, tappet, shoe and stamp head, which weights were guaranteed by us, the total of which was 1013 pounds. We submitted this specification and one of our representatives called on the purchasers regarding same. He was informed that while our specifications were very complete, and no fault could be found with our plant in any way, still our price was between $300 and $400 higher than that of the lowest bidder; that while they had a high regard for our machinery, etc., still they could not pay us $400 more than our competitor, whose machinery presumably was just the same.

Our representative suggested that possibly our competitor's machinery might not be the same, and suggested that the specifications be laid side by side and compared.

The first thing that developed was that their grizzly was 3x8 feet, made of plain bars 2½x⅝ inches, while ours was 4x10 feet, made of taper bars ¾-inch wide at top, ⅝-inch at bottom and 3 inches wide, thus making a grizzly which could not be clogged up.

His mortar was an unlined mortar, while ours was to be supplied with removable liners, thus making the mortar everlasting; the aggregate weight of his stamps could not by any hook or crook possibly exceed 950 pounds. His copper plates were 4 feet wide, 8 feet long, instead of 5x10, as in our mill, but the crowning thing of all was his steam plant, where he specified a common slide valve engine with cylinder 8 inches in diameter by 10 inches stroke, and horizontal tubular boiler containing only 210 square feet of heating surface, as against 600 feet of heating surface in our boiler.

His engine was an Eastern engine of well-known make, and our representative immediately procured the manufacturer's catalogue wherein the engine was rated at 13 H. P. and the boiler at 20 H. P. Both of them were overrated, as we only rate a boiler of that capacity at about 15 H. P. and the engine at 12 H. P. Our representative pointed out the fact that this engine and boiler could not possibly be made to run the mill when running at the speed recommended by the manufacturers, and at his suggestion the intending purchaser called up our competitor and put the question to him regarding the capacity of engine and boiler. His reply was that he intended to run the engine at 350 revolutions and carry 150 pounds of steam on the boiler. Our representative also pointed out the fact that the main drive belt on this engine was only 8 inches wide, the battery belt was only 10 inches wide, while in our specifications both of the above belts were 12 inches wide.

All of this goes to show that unless a purchaser is a mill expert, they often get fooled by various people who supply mills, and whose only idea is to sell them cheap. We do not care for this class of business and prefer not to build cheap mills. Salesman.

San Francisco, Cal., April 25.

Hints on Shaft Work.

To the Editor:—In view of the enormous expense incurred in shaft work and the necessity of capable and economical management connected therewith, a few hints of practical value may prove of interest to readers of the Mining and Scientific Press.

Occasionally we see statements made by managers setting forth the cost per foot of shaft work and pointing with pride to the low cost of same, but never a suggestion of how or under what conditions this was accomplished. On the other hand, I have heard managers announce at stockholders' and directors' meetings that shaft work cost from $90 to $120 per foot. It is easy to see what a 1000-foot shaft would come to at such a figure.

These reports are accepted by the stockholders, unconscious of the fact that such work should and could be done for from one-half to three-fourths of the above amount.

After you have decided what kind of shaft you want—and to my mind a vertical shaft is the only proper working shaft—the next thing is to introduce some system and religiously adhere to it. First of all, do not have too many bosses. Usually a superintendent goes to the sinking crew and gives certain orders; perhaps before he is gone ten minutes the foreman comes along and advises something directly opposite; then probably two or three shift bosses come along and make counter suggestions. So it is only reasonable to suppose that chaos is the inevitable result.

My idea is to give the foreman full charge of the shaft work, if he is capable, and if not, get some one who is. Then if the superintendent has orders to give, let them be given through his foreman. It is well enough to have shift bosses come around to see if the shaft men need anything, and if they do, procure it for them. For the aim should be to have the men in the shaft stay there and not be running all over the mine looking for tools, etc. To avoid this, as a means of communication with the top man, I have used what I call a tag board. A piece of board 6x12 inches is a convenient size, and have written on it, or better still burned on, everything liable to be needed in the shaft, and opposite each item a hole in which to insert a wooden peg. This board is fastened on the cable just above the hook so as to be in reach, and left there. When anything is needed all the shaft men need do is to insert the peg opposite the article needed and send the bucket to the surface. At a glance the top man sees what is wanted and sends it down. This keeps the men at their work and avoids the careful handling of men by the engineer. One of the greatest items of expense is the breaking of the ground, and care should be taken not to break too much out of the sides of the shaft.

The space between the walls and the timbers must be filled in and consequently is a lot of needless work, and besides is not so substantial. To avoid breaking too much ground out of the sides, or too little for that matter, I have used a plumb-bob attached to a light pole, long enough to reach the last set, by placing the pole, with plumb-line attached, in the corners of the set and letting the plumb-bob drop to the bottom; you can see at a glance how much ground is to come out. Aim at least to take out from 4 to 8 inches outside of the shaft timbers. This leaves enough room to get blocking and lagging behind the sets. Some men who profess to be miners try to

take too much ground out of the bottom at one setting up, and to that end they tell the men to drill 9-foot or 10-foot holes, then fill them with dynamite. The result is that it takes one, and sometimes two and three days, to replace the timbers that have been blasted out, and besides they don't break the ground clean, but leave it in such a condition that it cannot be drilled or picked out. When the men are shovelling have them pick the bottom carefully and be sure to take out all the shattered rock, for it is difficult to drill ground that is shattered.

Machine holes should not be deeper than 6 feet for cut holes and 5 and 5½ feet for back and center holes. Of course local conditions will sometimes vary this and judgment must be exercised accordingly, but the above should be the maximum depth. There is no necessity of blasting out timbers if a man knows his business. Miners like to use large quantities of dynamite because it breaks the rock finer and makes easier shovelling. When timbers are blasted out, caution the men and let them know it will not be tolerated; if it continues it is time to get a new crew of men.

The wall and end plates should be protected against blasting by nailing on the under sides 3-inch plank and leaving it there until you are ready to timber again.

Do not allow the timbers to get too far from the bottom—in fact as soon as there is room for a set, put it in. To avoid injury the guides when blasting have two sets of false ones, one pair long enough to reach between two sets, and the other pair long enough to reach three sets. It is necessary that at least one man on a shift should be a good timberman.

Do not have too many men in the shaft, especially when timbering. One man in each compartment is sufficient. If you have a machine crew of four men, when it comes to timbering send one of them to the surface to help the top man send down the set. He will be more useful there than in the shaft. I have made it a point to timber on the night shift, so as to have the timber framer have everything in readiness during the day. Have the top man place everything uecessary close to the shaft so that there may be no delay in getting the set down; have the hangers in good shape; have the staging ready at hand, and it should go down first of all; then the tools, axes, hammers, plumb-bobs, saw, nails, two picks and a few wedges; then the wall plates; be careful to send them down in pairs so that it will not be uecessary to send them to the surface again; then the end plates, posts and centers, now a bucket of assorted blocks (and plenty of them) and 3-inch wedges.

All this should be sent down without any delay, as the men in the shaft have nothing to do until the set is down, when they get ready to hang it. The set should be blocked in three hours at most, and then the lagging should be sent down. From the time the staging goes down until it is back at the surface again with the set complete, should not take over six hours. Yet how often is this done?

Do not allow every man in the shaft to ring the bell for the cage or bucket. Have one man on a shift do it and have him educated to do it properly. Do not give your machine men a starter and a 6-foot drill and expect them to do good work. Have plenty of steel and do not have three or four different sizes, for they will not follow in the holes and besides will cause vexatious delays.

If you are sinking by hand have each shift drill, blast, and send up their own rock, so that in case of missed holes they will know exactly where to look for them. Have a tally board at the top and tally the amount of rock sent up by each shift. This creates a rivalry and brings good results, but do not expect the shift that has to take out the cut to send up as much rock as the shift that comes after. Keep powder and fuse for your shaft men at the surface, and have the top man cut and cap the fuse during his spare moments.

If the ground is wet, fuse should be greased for 2 or 3 feet back from the cap so as to avoid gettiug the cap wet. These few suggestions have been tried and proven in actual work, and to some one lacking in experience their application may mean the difference between an assessment and a dividend.

A. R. McDONALD.

A BORAX DEPOSIT is located in the marshes south of Lake Alvord, Harney county, Oregon, which covers over 10,000 acres. With transportation facilities as they are at present, about one-fourth of this area is rich enough to pay for working. The product is shipped by mule teams to Winnemucca, Nevada, 150 miles distant. The ground is level and treeless, and is encrusted with a layer of salt 6 inches thick—sodium carbonate, sodium sulphate and sodium chloride being constituents of the crust along with borax. During the long, dry summers this material is shoveled up, dissolved in boiling water to which sulphuric acid is added, the solution decanted, and the boric acid obtained by precipitation as the liquor cools. From 5% to 20% of the raw material is borax. Four hundred tons per year was reported for the years 1898, 1899, 1900 and 1901. No production in 1902. The Rose Valley Borax Co. owns the richest of the marsh land. The deposits are renewed each year during the winter rains. Hot springs carrying borax are the reputed source of the mineral.

A Magnetic Separator.

Written for the MINING AND SCIENTIFIC PRESS by W. R. CRANE.

Of the special and successful methods of concentration in common use, that which takes advantage of the magnetic properties of minerals is not only one of the most interesting, but also one of the most successful for difficult separations.

The electrical concentrators, although belonging to the same general class, have a much wider application, being applicable, in fact, to the treatment of practically the whole range of ores.

Excellent descriptions of many of the older and better known magnetic concentrators, or separators, such as the Monarch, Payne, Wenstrom, Wetherill, etc., have appeared from time to time in the mining journals. The Cleveland-Knowles concentrator is one that has come to the notice of the writer in the Joplin lead and zinc district. A company known as the Joplin Separating Co. has a mill at Joplin, where they are handling zinc ores in which occurs disseminated pyrite, and are turning out a remarkably clean product.

Several years ago, when the zinc smelters were located at Joplin, the Wetherill people had one of their inclined type of magnetic separators installed in the smelter by the roasting furnaces, and it was handling zinc ores with such a high per cent of pyrite as to render smelting of the same practically impossible. These ores were roasted before separation was attempted, which is done also in the use of the Cleveland-Knowles separator.

Only those ores that have considerable quantities of pyrite in them are treated by this separator in the Joplin mill, and as a good many mines—or portions of mines—yield such ores, the need of such a separator is apparent. Many mines and mills would, in fact, have to shut down if there was no market for such products.

The schedule on which zinc ore contaminated with pyrite is sold is as follows: A discount of $1 per ton for every per cent above 1, which remains constant until 5% is reached, above which a still further reduction is made, depending largely on the character of the ore aside from the pyritic content.

The Cleveland-Knowles separator is a belt machine and in that respect is similar to several other forms. The construction of the magnets, as well as the method of discharging the concentrates, is different from that of any other separator and gives the separator its distinguishing characteristics. See accompanying engraving, Fig. 1.

Referring to Fig. 2, it is seen that above the horizontal feed belt, of a single machine or unit, which runs over two wide-faced pulleys, are two large cylindrical magnets. The belt is seamless rubber, 12 inches wide, and extends horizontally for a distance of 7 feet 3½ inches. It is kept tight by adjusting screws acting on a sliding bearing at one end of the machine.

A short distance above and partly to one side of the feed belt are the two magnets, which are mounted upon vertical journals. The journals are held in position and supported by two bearings—the lower being of the ordinary form, while the upper are ball bearings. The magnets are driven by bevel gears mounted upon two shafts that run transversely with the machine. Upon one of these shafts is the main drive pulley; the other shaft is driven from the first by belt.

The vertical distance between the feed belt and the horizontal face of the magnets is ½ inch, but may be varied by raising or lowering the magnets, thus enabling the operator to adjust the separator to suit the requirements of the mineral treated.

Attached to the supporting journals of the magnets and directly below the lower bearing are the continuous acting brush connections, one to each journal, by means of which conuection is made with the exciting coils of each magnet. The connections consist of two metal rings mounted upon an insulated hub, the rings being insulated from both the journals and each other. Two brushes attached through rods to an insulated disc, which in turn is fastened to a cross timber above, rub upon and make electrical contact with the rings. A heavy wire leads from each ring to the two ends of the wire in the coil or coils.

The cross sectional area of the maguets is the same, which, as the magnets are cylindrical, is the surface area of the faces. The diameter of the magnets is 26¼ inches, and as the feed belt is 12 inches wide, the former is 14¼ inches wider than the latter.

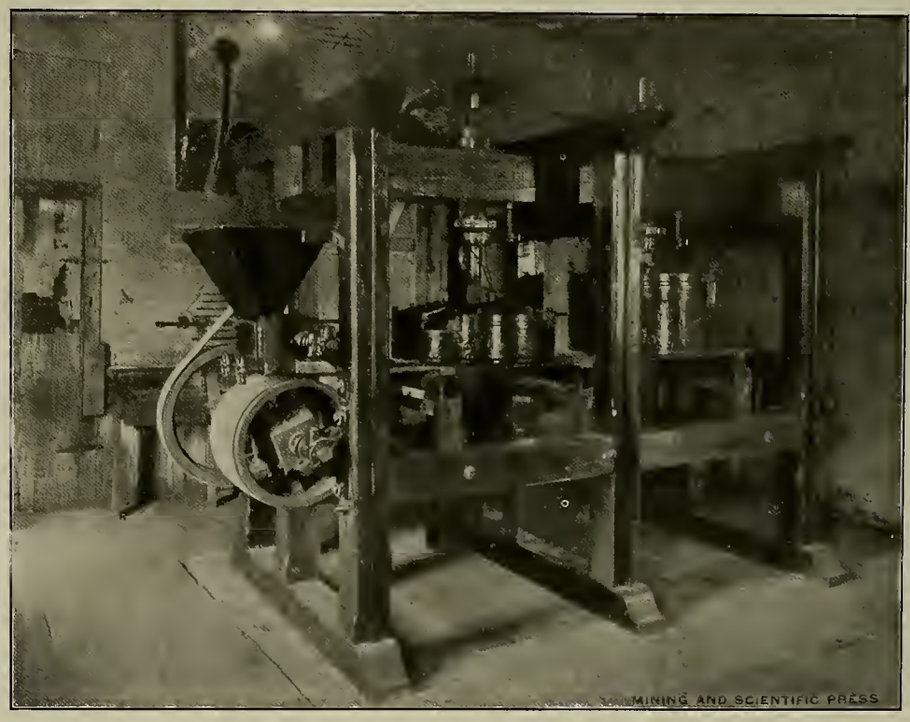

Fig. 1.—The Cleveland-Knowles Electro-Magnetic Separator.

The magnets are hung in the middle of the supporting frame, while the feed belt is set to one side in order that room for the discharge of the separated minerals may be had.

To prevent the belt sagging when loaded, and so increase and vary the distance between it and the face of the magnets, rollers are placed below the upper lap of the belt. There are three of these rollers, which are placed one between and one at the outer edge of the face of each magnet. The belt is supported at two diametrically opposite sides of the magnet, thus maintaining a fairly uniform space between the two parts, i. e., belt and magnet faces. The rollers are also made adjustable vertically, the supports being slotted below, and temporary adjustment, especially while in operation, is usually made here.

On the side of the magnets opposite the belt, or on the side where the larger part of the face is exposed, are steel knives or scrapers, which are fastened to the framework and extend across and press upon that part of the face of the magnets not covered by the belt. These scrapers do not extend radially with the face of the magnets, but are set at a considerable angle with the radii, thus acting as a plowshare in forcing any adhering mineral to the periphery of the magnets. They keep the face of the magnets free from accumulatious of mineral, which also aids in maintaining a uniform space between the belts and magnets. Directly below the scrapers—and, therefore, the exposed portion of the faces—are wide-mouthed hoppers, into which all materials scraped from the magnets are caught and conducted to separate boxes.

The magnets proper are very compactly built and consist of central, circular cores and encircling shells, which serve as the two sets of poles, respectively. The shells have flat annular faces, which form continuations of the bases or faces of the cores, when the two parts are bound together by the surmounting yoke. Through the yokes and extending iuto the core to a depth of 3 inches is a hole, which is the seat for the supporting and driving journal. Within the

annular space left between the core and the outer shell is placed one or more coils to each magnet. Between the coils and the metal of the magnets, as well as between the individual coils, when more than one is employed, are placed strips of wood or wooden washers for insulating purposes.

The coils are square in section, are made of well insulated wire and are, when formed, served with tarred rope. They have inside and outside diameters somewhat larger than that of the cores and the inside diameter of the shells, by which arrangement there is a dead air space between the coils and the metal on the sides, while the wooden washers give the desired insulation above and below. Connection is made between these coils and the feed wire brought
